Sweet William.—During the week, a large quantity of Sweet William was put out from nursery beds. This ought to have been planted long ago, but the untoward weather proved an obstacle, and it was decided to wait till early spring before moving them. The soil is now in excellent condition, the plants are thrifty and robust, so that there seems to be no reason why they should not succeed.

Bedding plants.—With the potting of a final lot of *Salvia* *Pride of Zurich* from the propagating pit, the increasing of hedding plants has terminated. More Zonal Pelargoniums have been mossed up, and meantime placed in heated pits. Pricking off is regularly done as occasion requires among seedlings; and in the course of the week full sowings of Ten-week Stocks and of Asters were made. The latter sowing included the popular single varieties which are appreciated for cutting. Further and final sowings of Antirrhinums were made. Plants from such sowings are valuable for late flowering.

Hardy-flower borders.—A beginning was made in the course of the week with the tidying up of the hardy-flower borders. These are rather extensive, and entail a good deal of work at this time. Stakes of a suitable length are placed in position, and afterwards the borders are hoed and raked. When this is completed it is possible to see where a colony of hardy annuals would be effective, and sowing is done without delay in such places. Bulbs in these borders at present make an excellent show, and when their season is over and the foliage ripened off the vacant spaces are temporarily filled up with any left-over hedding plants which will not unduly exhaust the soil. Among other things just now in bloom may be mentioned the *Pulmonarias*. Any stools of *Delphiniums* or of similar rather gross-growing subjects may with advantage be thinned at present. This makes the flowers upon the shoots which are left much finer, and the cut-back stems very often break again and provide a second show. This, if not so fine as that early in the season, is always useful and prolongs the season of these favourite hardy plants.

General work.—With the exception of China Roses the pruning has been completed. Plants in cold-frames are being freely exposed with a view to placing them outside in a sheltered place at an early date. The borders intended for Dahlias and Sweet Peas were stirred up after being dressed with soot, and a beginning was made with the trimming of Grass verges.

Vegetable garden.—No work of any importance was carried out during the week; sufficient sowings and plantings have been made for present requirements. A quantity of Leeks was lifted and laid in, and the break prepared for digging. Cauliflower plants raised in heat are now being hardened off. By planting in trenches and covering the plants with inverted flower-pots at night, Cauliflowers may now be risked in the open air.

Under glass.—The work under glass has again given way to the more pressing work out-of-doors. The usual attention in respect of watering is increasing daily, and takes up more time. Ventilation is freely given alike in fruit and plant houses on all suitable occasions. Rather attractive in a greenhouse just at present is a number of pans of *Myosotis*. The variety, *Royal Blue*, is a dwarf one, and, like *Primula malacoides*, is much more effective in good-sized pans than in pots.

W. McGUIFFO.

Balmoe Gardens, Kirkcudbright.

The late Mr. F. C. Drew.—Trustees have been appointed by the University College, Reading, to administer funds given and accruing to the late Mr. F. C. Drew, on behalf of his wife and family (eight children all under the age of fifteen years). The trustees, who consist of the Registrar at the College, Mr. Herbert Sutton, and Miss Lucy Ashcroft, Professor of Education and Mathematics, will do their best to help Mrs. Drew, and assist in placing the children in suitable schools and positions in life and administer to the funds for their benefit. Subscriptions have been sent to the trustees by his present and past pupils, and it is thought that many of his old friends would like to send a contribution, which they can rely upon the Trustees using to the best possible advantage. Donations may be sent to the Registrar, University College, Reading.—LEONARD SUTTON.

NOTES OF THE WEEK.

Botanical rigmaroles.—I notice in the paper some people use Latin names for Elwes' and Whittall's Snowdrops. I have grown both and many others, and I think they are two forms of one species. It is much simpler to say the Elwes or the Whittall form than use a double-barrelled Latin name.—W.

Cytisus Hildebrandti.—This has been finely in flower in the Royal Botanic Gardens, Edinburgh, under glass this spring. It is an early bloomer, and should have the shelter of a cool-house. In Edinburgh it is planted out, and makes a good bush 4 feet high or a little more, covered with bright yellow flowers. It promises to make an excellent pot plant.—Ess.

Double flowers.—When "W." was finding fault with double flowers, he might have included Cinerarias. Surely of all doubles, double Cinerarias are the worst. For double Camellias, there is this to be said: A relation of mine who lived in Brittany, and in whose garden Camellias took the place of Laurels with us, told me the double Camellias were harder than the single.—F. G. DUTTON, *Bibury Vicarage, Fairford*.

Narcissus nanus.—I think J. Cornhill's note as to the above being "easily grown" is a little misleading. Here (Co. Cavan, Ireland) I cannot keep it alive, although almost all other Narcissi grow and bloom magnificently, and increase almost too rapidly. I have bought bulbs of nanus again and again, but they rot away, so I have given it up, although with extreme regret. My garden is rather too flat and the soil heavy clay, which is very wet and sodden in winter.—A. B. M.

Iris reticulata.—As "W.," page 189, asks for experiences with regard to Iris reticulata, I will give him mine. I am on oolite limestone, and the rock is about 6 inches below the surface. So the garden has had to be made. It slopes to the south. I. reticulata used to do very well. Now I have one strong clump, and the others do not seem to increase. When they succeeded I had a gardener whose strong point was not watering. Now the borders are carefully watered, and, though I give instructions to avoid watering the Iris, it is not very easy to observe it in the case of the small clumps. I have inferred that a fairly deep soil and no watering are what I. reticulata likes. My I. stylosa began flowering on September 12th, and is

still going on, which I think is pretty good.—F. G. DUTTON, *Bibury Vicarage, Fairford*.

Heloniopsis umbellata.—Of this I saw a very good plant in bloom in the Royal Botanic Gardens, Edinburgh, on April 5th. It was growing in one of the borders in the front of the range of houses. The long, rather strap-shaped leaves were surmounted by a number of flowers of a pleasing pink, arranged in umbels on the short stem. It is far superior to H. breviscapa, and a good rockwork or border plant. H. umbellata comes from the Island of Formosa.—S. ARNOTT.

Anemone rupicola.—In the Royal Botanic Gardens, Edinburgh, this is evidently quite at home in the rock garden, where it is now in flower. At the Chelsea Show of 1915 its value, when shown by Bees Limited, was recognised by an Award of Merit. Its height is barely 9 inches, and above the Apple-green leaves are borne the silky flowers of pure white, tinged in the young buds and in the flowers which have been longest expanded with a pale blue. Sandy loam in the border or a well-drained spot in the rock garden would appear to answer well for this fine Himalayan Windflower.—Ess.

Polyanthus Munstead strain.—We have this in Sheffield, but down here (Surrey) it seems to do much better, and is now (April 12th) covered with bloom, and has been so, I understand, for a month or more. The flowers are white, cream, yellow, and orange, and whole beds are planted with them. Seed should be sown in a shady border now, and the plants pricked off and grown on rapidly. They should be planted in their flowering quarters in October. The soil should be moist and fairly rich, and the plants should be set out 1 foot or 9 inches apart each way.—E. T. ELLIS, *Moor Edge, Walton-on-the-Hill, near Epsom*.

Trees and the storm.—A great number of fine old Elm-trees and several Beeches were uprooted by the blizzard on March 28th. In other cases the trunks have been snapped off about 10 feet from the ground and some of the strongest boughs broken like matchwood. Cedar-trees also suffered badly, and in some cases are completely ruined. Some fine trees of Cupressus Lawsoni erecta viridis, 30 feet to 40 feet in height, were uprooted. A most picturesque old Yew-tree, standing in the centre of the rock garden, was badly damaged, quite half of its very large branches being snapped off close to the

trunk. I hear that the Cedar at Titchmarsh Rectory, reputed to be the finest in the country, is completely ruined.—F. W. GALLOP, *Lilford Hall, Oundle*.

Flowering Cherries.—Mr. E. H. Wilson's notes on these on pp. 167-8 are interesting and should prove useful. Regarding those which are frequently grown the following may be useful:—P. Sieboldi, of Wilson, generally called Watereri in nurseries and gardens, comes into flower about a fortnight before James H. Veitch. These two are followed by what one would consider a variety of the latter and called "New Rose" by the French nurseryman from whom I obtained it. This last-named is not so free-flowering as the other two, and the blooms are but little darker than those of James H. Veitch, which are deeper in colour than those of Sieboldi.—S. ARNOTT.

Glory of the Snow (*Chionodoxa Lucilæ*).—Few hardy flowers have attained to such popularity in so short a time as this. The lovely colour of the flowers, and the early season at which it blooms, render it one of the most precious among hardy bulbs. To see this little gem at its best it should be planted in colonies of half-a-hundred or more bulbs. Fortunately, bulbs can be procured at a very moderate outlay, and, once planted, they are a joy for ever. The Snow Glory is as hardy as the common Snowdrop, and will flourish in almost any kind of soil. It comes into flower with the little Siberian Squill, for which it is an admirable companion. The colour of the Squill is richer, but the Snow Glory is, I think, the more effective of the two, being of more robust growth, while the flowers have a white centre, which renders them very conspicuous.—T.

Notes from Surrey.—Things are much more forward down here than they are in Sheffield gardens. The borders are gay with Primroses, Polyanthus, Anemone apennina, and Hepaticas, as well as the fine, large, double Daisies, Wallflowers, and Hyacinths, and the rock garden is full of single Arabis, Scillas, Grape Hyacinths, etc. There will soon be Tulips in bloom out-of-doors, and the Fritillarias will be out in a day or two. This is very different from our Sheffield gardens. We had plants in bloom in January and February, but March was a blank month, for we were snowed up most of the time. When I left Sheffield, however, I noticed that Arabis, Doronicums, and Alyssums were showing bud, and that Aubrietias were coming into bloom, but I consider

this very early. Usually, it is not our good fortune to have these plants in bloom till late April, and sometimes they do not reach their full glory till mid-May.—E. T. ELLIS, *Walton-on-the-Hill, near Epsom.*

Herb gardens.—I have been acting devil's advocate in regard to these, which people have been getting up meetings to promote. I have tried to point out that it is a foolish game, as the demand for herbs is likely to be a very small one. After the war there will be so many countries more suitable for growing the plants that it can never be any material gain to grow them in this country, and it would be much wiser to devote the land to the production of food. The doctors themselves tell us to use as few drugs as possible. There are, perhaps, half a dozen useful and difficult to get, but the more our knowledge of drugs grows the more do people think that the best drug is no drug. Some people also think that the use of drugs is a national danger and cause of permanent ill-health to people who doctor themselves and believe the quacks.—W.

Scented-leaved Pelargoniums.—Signs are not wanting that the merits of these are being more generally recognised. This is not to be wondered at, as Pelargoniums of this section are remarkable, not only for the fragrance the foliage possesses, but also for the many varied scents to be found among them. The Citron-like smell of *Pelargonium crispum* and some others, and the Peppermint scent of *P. tomentosum* furnish cases in point. Added to this, the flowers of some of the scented varieties are very pretty. One of the most recent of this section is *Clorinda*, which was given an Award of Merit a few years since by the Royal Horticultural Society. The rose-coloured blossoms of this variety are large and showy, and immense numbers of it have been sold since it was first distributed. A very old class, yet, at the same time, combining fragrant leaves and showy blossoms, is the different forms of *Unique*. All are of a rambling habit, and at one time used to be trained as specimens, while they are also well suited for growing as wall or rafter plants in the greenhouse.—W. T.

Cupressus Lawsoniana, var. erecta viridis.—This has suffered during the recent rough weather, the branches falling about and making great gaps in the tree. As a small tree it has some value, and will then stand storms with immunity. Its dark green colour, too, at all seasons of the year, is not without value. I pity those who have many old specimens, for they are a continual source of expense and trouble. I have spent hours after a storm lacing in the branches in order to give it a respectable appearance, but this always seems wasted labour and material. I saw this tree used in quantity when visiting a Sussex garden during the past summer. It had been planted in two rows along the side of a raised terrace fully exposed, and a more bedraggled lot could scarcely exist. The lower parts of the tree had become naked, and the lumpy branches which had broken loose showed great, dead-looking holes which had been caused through the excluding of light and air by the thick habit of growth. With such a number of these it would be almost impossible to keep them laced in, with the result that they become fitting subjects for the fire. The species in a wild state reaches 200 feet in height, and is one of our most valuable trees, and perhaps one of the most planted of the Cypress group. When breaking into new growth in early summer it is very attractive; also when in flower; and lastly, is immune from all the troubles associated with this fastigate variety.—E. M.

FRUIT.

TAKING CARE OF THE FRUIT.

The present price of sugar, with an ever-upward tendency, is regrettable, and will, I fear, press rather hardly on cottagers, lessening the prospects of home jam-making and the sale of fruit not required for home consumption. The various jams will be greatly missed, especially where there are children, and under the circumstances it will be advisable to direct increased attention to bottling the fruit, also to have it riper than usual, so that when required for use only a very little sugar will be required. This applies to the different Currants, also Gooseberries and Plums, which are not much appreciated if too sharp. Any measures that can be taken to ensure the keeping of fruit and having it at its best will be welcome—a fact that was emphasised the other day (April 10th) when some nice baskets of Blenheim Apples were removed from their winter quarters in first-rate condition. I determined to let them hang last autumn as long as possible, the result being that they have kept sound and plump with no shrivelling. A few of the best fruits that had been tapped were treated with plaster of Paris, and have come through equally well. Fortunately, however, the birds are nothing like so fond of Blenheims as of some varieties. The above fruits are those mostly represented in small gardens. An occasional Pear furnishes material for dishes of stewed fruit, but these old kinds take an extraordinary time in the cooking, and are most acceptable for the purpose after they have been bottled. It is probable that the price of sugar will also have a prejudicial effect later on on the use and sale of Blackberries. E. B. S.

Hardwick.

ECONOMY IN THE GARDEN.

It is only fitting that all those who have charge of gardens should see to it that there is no waste at such a time as the present. It is not possible to lay down strict rules as to how this is to be effected, for what is applicable, and at the same time most suitable, in one garden is not so in another. In several cases the same rule will apply. Paths and roadways will not come to much harm if some of the labour in upkeep be withdrawn for the time being. Keep the gullies and drains in good working order by all means. It is also possible to dispense with the cutting of turf verges for one or two seasons; in fact, it is my opinion we do too much of this work. Again, dispense with the use of stakes for all herbaceous plants. This has been done, I know, in one instance, and with manifest advantage, and at least a fortnight's labour for two men has been saved. If any support be needed, use a few old stubby Pea boughs for the tallest plants, and stubby, worn-out brooms for shorter kinds. In this way the effect is much better and far less formal. Avoid any renewals of turf if possible, as this means labour; rather scatter a little lawn Grass seed and trust to its effect. Defer for another season, at least, the removal of shrubs of any considerable size. This, too, makes a lot of labour, not only in the proper and safe removal, but in the after attention to watering. Dispense for one season with the replanting of herbaceous borders by the division and planting afresh of the stock thereof. These are a few instances of what may be avoided in the general upkeep of the pleasure grounds. On the other hand, do not, if it be at all possible, neglect the forking over in the winter of the ground among shrubs.

When the work is neglected the shrubs will feel the effect when dry weather again sets in. Do this work and also prune all shrubs as usual that are known to be more effective when this is done annually and in its proper season. Climbers have often far too much labour bestowed upon pruning and nailing, just for the sake of formality. Some economy, too, may be carried out in the

KITCHEN AND FRUIT GARDENS. Here but little harm will come to any crop if the trenching two and three spits deep be reduced in its extent for a season or two. A few crops do better under deep trenching, but many others do not need it every year. Aim at rather small or moderate-sized examples of culture in preference to overgrown specimens, such as find favour on the exhibition table. We should do better if we grew more of the dwarf or semi-dwarf Peas that require but little staking. Here, again, is an instance of saving labour both in staking and in the preparation of the stakes. Runner Beans may be grown as the market gardeners grow them; true, the pods will be smaller, but they will be all the better, if gathered early. With both Peas and Runner Beans what is needed is more seed, and so let the rows be as close again. This will be in favour, surely, of the seed merchant! With respect to Lettuces, let the smaller varieties be grown rather than the big examples. Depend upon the small Carrots rather than upon the big examples. The same applies to Onions and Leeks for home consumption. Grow more of the smaller varieties of the Cabbage family. Make every effort to keep the hoe in use, even if some things are for the time passed by.—J. HUDSON, in *The Garden.*

MELONS IN FRAMES.

With but little time to spare for the making up of hotbeds specially for the growing of a summer crop in frames, some of the latter, now filled with Potatoes, will, as soon as they are cleared, be used for the purpose. The soil will be removed and the portions of the existing bed covered by the frames will then be renovated by the addition of some fresh stable litter. This, when fermentation has set in and the heat begins to subside, will be trodden firm and a mound of fibrous loam enriched with a little bone-meal, and a sprinkling of lime-rubbish added to ensure a firm, fruitful, rather than a soft, long-jointed, growth placed on the bed under each light and well rammed. Each mound will be of sufficient capacity to accommodate and support two plants—one to fill the top and the other the lower portion of the bed under each light—until "setting" of the fruits has taken place, when they will be added to. To prevent heat rising and filling the interior of the frames with steam charged with ammonia, the surface of the bed, after the mounds have been made up thereon, is covered with loam about an inch in depth and trodden down. Whether linings will be required will depend on the amount of heat which will result from addition of the stable-manure to the old material and outer climatic conditions also. In the meantime, the necessary number of plants will be raised, the seeds being sown singly in small pots filled with loam in a moist condition to obviate the necessity for applying water until germination takes place. To strengthen the plants the first rough leaf will be pinched off, and planting take place as soon as the pots are well filled with roots.

Early Melons.—Wintry weather and economy in regard to fuel have not been

conductive to the hastening of the growth of early Melons; still, with lengthening daylight and a prospect of brighter weather, a certain amount of leeway can be made up if the utmost use is made of sun-heat. Plants developing laterals will, if they fail to show a sufficiency of female flowers, be pinched to make them break, as the resulting growths are then invariably fruitful. The points of the main stems should at this stage also be stopped, as this leads to the production of a further relay of laterals, which may be depended on to fruit also should they be required in consequence of those first produced failing to do so satisfactorily. The main object is, of course, to obtain a sufficiency of laterals carrying female flowers that will open simultaneously, and unless this follows, a good crop will be looked for in vain. These fruit-bearing laterals are pinched at the first leaf beyond the flowers, which tends to strengthen and hasten their expansion. With the soil at this stage kept rather on the dry side, the female flowers, when fully expanded, set freely

PLANTS AND FLOWERS.

ROSES.

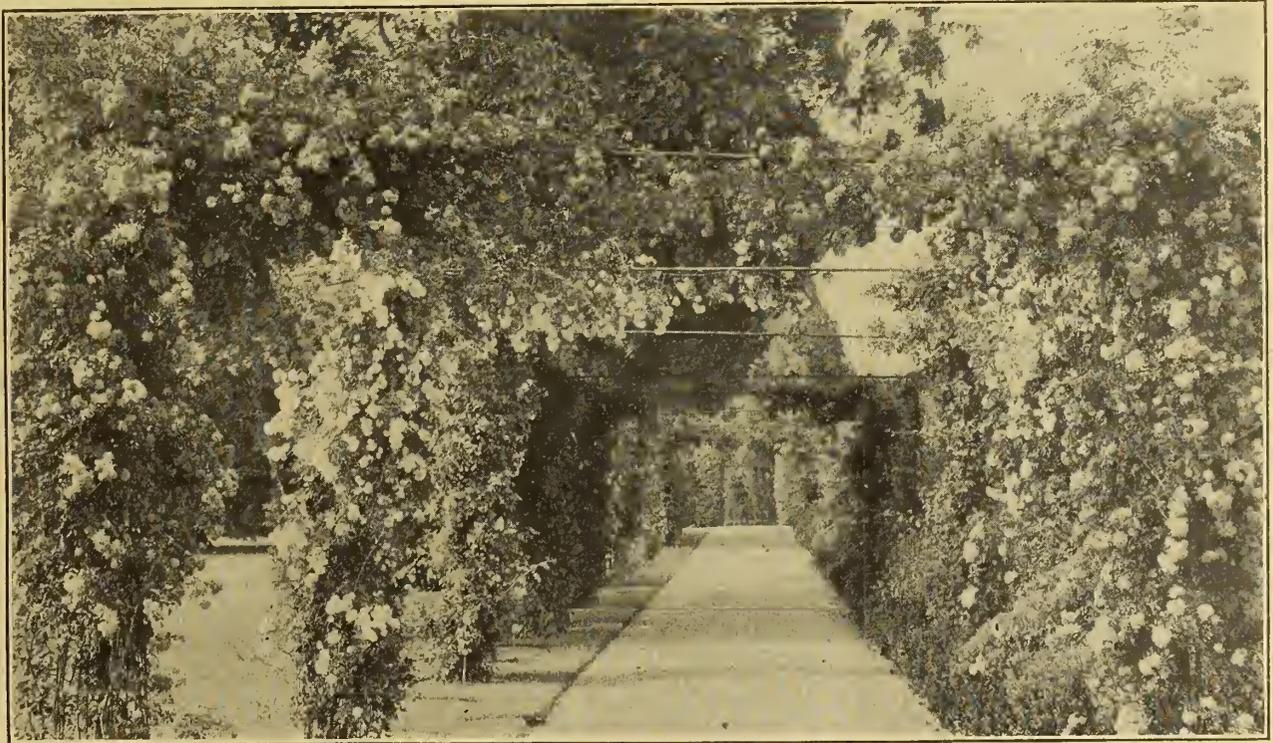

CLIMBING ROSES AT KEW.

ARCHES, pergolas, pillars, and trellises are among the most favoured methods of displaying the beauties of the Climbing Roses, and something answering one of these descriptions is generally to be found even in the smallest of flower gardens. The long, straight walk, spanned at intervals of 4 feet or so by iron arches, covered from end to end in the summer with a wealth of Rose blossom, is a feature in any garden. The illustration we give to-day shows the Rose pergola at Kew, which runs for a distance of nearly 250 yards between the rock and Iris gardens on the one side and the herbaceous ground and water garden on the other. The pergola is constructed of light iron bars. On it most of the best of the old and new varieties are thriving well, and in the season of bloom are

cases hard pruning will have to be resorted to in consequence of so much of the young wood having been killed by the frosts in the early part of March. At the time this occurred, the buds on the upper portion of the majority of the best of the growths had started, and in many cases had made as much as 2 inches of growth. Both these and the wood on which they originated succumbed when overtaken by the frosts alluded to, and have since presented a rather melancholy spectacle. Care will be taken to cut back in every case to live wood, and although the result is that the pruning is of a more severe nature than usual, the bushes will no doubt in the long run benefit by it. When finished the beds will be dressed with an artificial Rose manure, which will be pointed in.—G. P. K.

THE LATE PLANTING OF ROSES.

OWING to the unfavourable weather during March many growers have been obliged to delay planting their Roses until

Climbing Roses in the Royal Gardens, Kew.

after having been pollinated about mid-day, the fruits swelling off at once when well watered two or three days afterwards. After this, flowers of either sex are suppressed and the laterals and sub-laterals kept pinched at the first leaf. Ample supplies of tepid water alternated with stimulants are then necessary, and to encourage the increase of feeding roots additions of compost are from time to time required. For the benefit of the uninitiated it should be stated this is not applied in the same way as for Cucumbers—*i.e.*, on the surface of the soil in which the plants were set out, but at the outer edges in the case of mounds and raised borders, and round about the mound in the centre of pots, provision for which was made at planting time. This preserves the stems from risk of canker, which might possibly ensue if they were surrounded with fresh compost. A humid atmosphere is at all times essential from now until the fruit matures, and embrace the opportunity whenever possible and secure a temperature of 90 degs. with the aid of sun-heat by closing early.—A. W.

wreathed with flowers, the view from end to end being a continuous display of changing colour. Among those planted are Tea Rambler, Queen Alexandra, Leuchstern, Dorothy Perkins, Hiawatha, Carmine Pillar, Una, and others. Much has been written against the employment of iron arches, but where these consist of simple rods and so stayed together that they are secure against the effects of gales, they are so speedily covered by foliage and flower as to be entirely lost to sight. Another merit possessed by such arches is that being so slight they throw no shade, and, if not set too close together, the sunlight filtering through the loosely-trained growths permits Roses to form and expand beneath the arches as well as above them.

Rose pruning.—With the exception of Teas and their hybrids this has been brought to a close, and the beds are now being manured and lightly dug over. The pruning of the above-mentioned will be taken in hand forthwith and completed without delay. In the generality of

a very late date, and some have possibly not been able to complete the planting even yet. The question arises, "How late in the year can Rose-planting be done with a chance of success?" This depends upon the condition of the soil at the time of planting, the method of doing the work, and the attention given to the plants afterwards. I have planted large numbers of Roses as late as the last week in May and have lost only a very small percentage. To be in good condition for planting, the soil should be fairly dry and friable, for if it is at all sticky it is sure to bake hard in the sun, and this will hinder the formation of new roots. Where the soil is naturally very heavy it should be ridged, or thrown up very rough, early in the season, when the frosts, winds, and rains will pulverise it and get it into good planting condition for the spring. Where this has not been done it would be advisable to have a barrow-load of fine, loamy soil at hand, a shovelful of which should be worked in among the roots when planting. For spring planting "retarded" plants, that is, plants that have been dug up early

in the season and "heeled in," are far superior to those taken straight from the ground.

Before planting, cut the bushes back hard, leaving only two eyes or three eyes to each shoot, and carefully trim off the bruised ends of the roots. Open a fairly wide hole, so that the roots may be spread out and not cramped, dipping the plant into a bucket of water before planting. Roses like firm planting at all times, but especially in the spring. The actual surface-soil should not be trodden down, but be left fine, to form a tilth. Give a good watering immediately after planting. Subsequently water when the young shoots seem to be flagging, this attention being more necessary in light than in heavy soils. The moisture will be retained much more readily in the beds if a fine, loose surface is kept, and this can only be done by frequent hoeing, especially after rain and the application of water. Given such treatment there is no reason why dwarf Roses planted as late as May should not give quite a good show of blossom in the late summer and autumn. Climbing Roses planted now should be cut down just as rigorously as dwarfs, when they will make a lot of new wood, which will produce a grand display during the following season.

E.

PEGGING DOWN ROSES.

It is surprising that the pegging down of Roses is not more generally practised. The finest varieties for pegging down are those that every year make long, sturdy growths, which should be left full-length when pruning, all the smaller wood being removed. These long rods are then bent over gently and fixed about a foot above the ground-level by means of a peg. The pegs should be of good length, so that they may be driven well into the ground, for the bent shoots exert a considerable strain. Cultivation, too, should be of the best, a quantity of good old manure being forked into the beds each spring immediately after pruning is done. The pegging down of the shoots induces the plants to blossom so profusely that unless given plenty of nourishment they cannot possibly stand the strain many seasons and continue to produce new growth at the same time. It is likewise necessary to remove all useless wood, and also the pegged-down shoots directly they have done flowering, so that the energies of the plant may be utilised in the production of strong new rods for the following season. Those who have never tried this way of growing Roses should pay a visit to Kew Gardens during the Rose season, where several fine groups are to be seen, the plants literally smothered with bloom. When planting Roses for pegging down, place them at least 4 feet apart or the bed will become over-crowded very quickly. Equally effective groups may be formed by planting some of the perpetual-flowering climbing Roses, but these will need to be at least 6 feet from plant to plant.

D. N. E.

NOTES AND REPLIES.

Rose-trees unhealthy.—Kindly inform me what is the matter with my Rambler Roses, of which I send a few pieces. There is a growth round each shoot, and three trees which are within about 10 yards of each other, and in a sheltered position, are affected. Would you give me your advice as to how to treat them, and whether the peculiarity is likely to impede the flowering?—B. S. HUGHES.

[The Roses are forming great numbers of adventitious buds (as supplementary buds are called) about the base of each growth. This will probably prevent or interfere with the flowering of these shoots very seriously, and we think it would be well to cut down all the affected shoots so

as to induce new growth, and at the same time to top-dress the soil with manure or with good loam and manure, so as to encourage root growth. Is the drainage all it should be?]

H. T. Rose H. E. Richardson.—Growers in Scotland with whom I have come into contact have been very pleased with this Rose. It is a vigorous grower, bearing its flowers well on short, erect stems. The colour, a deep, rich crimson, is combined with charming form.—SCOTCH ROSE.

FERNS.

THE COMMON POLYPODY.

I AM pleased to see that I am not alone in estimating the common Polypody at its true value. I cannot say that I have seen it used in the way "E. M." describes as a carpet for bulbous flowers, but I can well believe that it is one of the best things that can be employed for the purpose. "E. M." alludes to the influence of shade on the growth of this Fern. I have grown it in all positions, and certainly in partial shade the fronds are larger and deeper in colour. On the other hand, they are more lax, are not so erect, and do not show the yellow spore-cases. The more open the position the more is the fructification displayed, and as it is so abundant it adds to the attractions of this Fern. Wherever I have seen it growing naturally it has invariably been on dry banks in a more or less open position. It does not seek the shade and moisture which nearly all other native Ferns do. I have seen it on a bank in very sandy soil and far removed from anything that could afford shade or shelter, but it is possible that there may have been trees there in former days. The fronds were very short, but perfectly healthy. The ability of this Fern to resist long periods of heat and drought in full exposure to the sun is very great. I have a lean-to greenhouse facing south which was built some forty years ago. The woodwork has been renewed, but the wall has never been pointed, and has, therefore, become a bit crumbly and Mossy. Some years ago one little plant of the Polypody appeared, and this in time became a fruiting plant and was the beginning of colonies which increase annually in strength and numbers. I suppose that if I lived long enough I should see that wall pretty well covered with verdure. How that Fern lives in a time of great heat I cannot imagine, and apparently without moisture at the roots, but it does. It certainly looks at times rather shrivelled, but in early autumn new fronds are made, and from that time all through the winter the fronds remain of a rich green, as deep in verdure and as large as is the case when in apparently more favourable circumstances. Some of the fronds are quite a foot long.

I do not think that the most is made of our British Ferns. I do not mean the crisped and tasseled varieties, which, we know, get their full meed of attention. It is the typical forms I am thinking of, and which, so vigorous and enduring, so easy to please, are at home among a stronger vegetation and can be used freely and will create an effect where so many things would fail, either partially or completely. The effect which these common Ferns create when judiciously planted is remarkable; they put quite 30 per cent. on the appearance of any garden in which they may be used. I had occasion to note this in the case of some villas the gardens of which were of the ordinary stereotyped style—Grass lawns with flower beds and shrubberies composed of the usual assortment of Laurels and similar cheap, common things for which selection we have to thank the speculative builder,

who, in a general way, knows little and cares less about the many beautiful trees and shrubs in cultivation, and whose sole object is to furnish the place at a minimum of cost. It makes me feel sad when I see how nice gardens have been, in a measure, spoiled in this manner, and how little variety is to be found in them. In contrast to its fellows there was one on which the eye rested with pleasure and which owed its superior attraction and distinction to the presence of large clumps of the Male and Lady Ferns which were rather freely used. These Ferns impart brightness and informality where more rigid forms of vegetation predominate, and they are so inexpensive that they come within the reach of the slender purse.

J. CORNILL.

OUTDOOR PLANTS.

HARDY FLOWER NOTES.

SAXIFRAGA COCHLEARIS MAJOR.—The true variety of this is a handsome Saxifrage, and by reason of its very bright encrustations quite a prominent feature in the winter. During the winter I know of no other encrusted kind that so well resists frost, snow, and heavy rainfall. Some kinds are, of a dull colour, and all seem to be more or less affected by weather influences, but *S. c. major* has gone through the most inclement time experienced for many years, and is quite unaffected. Small though this Saxifrage may be, there is a nobility about it which distinguishes it from the generality of its kind, and it is certainly much superior to the type, which sometimes does duty for it. In fact, I grew the latter some years under the name of major, and my plants were obtained from one of our leading hardy-flower specialists. There is no mistaking the two when seen together, the variety being considerably larger and much more silvery. My stock is very limited, and I have never seen it in the form of large clumps, but should say that for winter effect it must be one of the best dwarf-habited plants in cultivation.

PYRETHRUM ULIGINOSUM.—An inmate for many years of English gardens, this useful hardy plant remains the same. It is a pity that the same improvement cannot be made with it that has been effected with the Moon Daisy. The typical form of this was never in the true sense of the word popular. It was too coarse, the disc being too large. Now we have a number of varieties ranging in height from 2 feet to 4 feet and differing considerably in form. It is a pity that the same improvement cannot be effected with this Pyrethrum, and doubtless it could be done, but it would be a matter of raising a number of seedlings annually and taking advantage of any break, however slight, that might appear. When the autumns are sufficiently fine to allow seeds to ripen, this might easily be done. This plant, on account of its late blooming and the ability to withstand climatic vicissitudes, is most valuable, but it is wanting in refinement.

CEPHALARIA MONTANA is a good thing for the wild garden or for planting among low-growing shrubs. In the herbaceous border it is out of place, being of rank growth, and, therefore, liable to encroach on the ordinary inmates of a flower border.

ASTER THOMSONI.—Notes on this species have appeared recently in GARDENING ILLUSTRATED, and it certainly deserves a good place in the flower garden. It cannot compare in decorative worth with *A. Amellus bessarabicus*, which it somewhat resembles in habit of growth, but it has a long season of bloom, and from what

I have seen of it it does not need frequent transplanting. My experience is that it is rather impatient of removal, and takes a season to recover when divided. Being of dwarf growth and unlike its near relatives, the Michaelmas Daisies, not spreading rapidly from the roots, it is a good thing for the owners of small and medium-sized gardens. This Aster is worthy of more extended cultivation.

J. CORNHILL.

VIOLETS.

In addition to the interesting information on the cultivation of Violets given in a recent number, it may be noted that a border facing somewhere between north and west is the best place for the cuttings, as under such conditions they are shaded a bit when the sun is at its strength. Failing such a position, I have found it advisable to shade a little artificially. The foliage of Violets is very susceptible to the attacks of red-spider, and this is aggravated when the plants

A way of staking Delphiniums. From a photograph sent by Mr. C. Turner, 3, Kenwood-road, Highgate, N.

are exposed to very hot sun and allowed to get dry. It must not be allowed to make headway or the foliage will be crippled and the number and quality of the flowers considerably lessened. One of the best remedies I ever found, to be applied as soon as the attack was noticed, was to knock up some fresh horse-droppings with a fork, mulch the surface of the ground with these, and give a good soaking of water. An examination of the foliage the day after the application found it free of red-spider, which evidently cannot stand the aroma that rises from the saturated droppings. Bearing in mind the susceptibility of the Violet foliage to such attacks, it is not advisable to put the plants in close proximity to anything that might be similarly affected.

I think it probable we might learn some useful lessons in the cultivation of garden Violets by a consideration of the circumstances under which, in some districts, the wild forms show to the best advantage, notably in the way of soil and situation. It seems strange and a little difficult of explanation why the blue and white forms

should individually be strongly represented in certain districts. Here, for instance, in mid-Bucks, I should think the white is in the proportion of fifty to one—indeed, on long stretches of bank one hardly sees a blue flower. E. B. S.

Hardwick.

STAKING HARDY PLANTS.

The illustration we give to-day shows an original way of staking Delphiniums, by using branching Pea-sticks, thus giving a far more natural effect than is possible by tying each flowering shoot to a stiff stake. In one garden we know, the owner always uses spray branches for supporting his Carnation flowers, all of which are then seen to advantage, while it is far easier to gather any blooms that may be required for the house.

ANNUALS.

THESE will be largely employed to take the place of half-hardy annuals and many other subjects used in previous years.

form of *Nigella*, named Miss Jekyll, should be grown in good-sized clumps, and the same with regard to *Lavatera rosea splendens*. *Layia elegans* is well worth growing, and *Phacelia campanularia* is a gem for the front of a mixed border. Though the flowers are not very showy, and close up in the day time, good large breadths of the Night-scented Stock, *Matthiola bicornis*, should be found room for.

Though the fringe of the subject has, so to speak, only been touched upon, enough has been said to show what a fine floral display and what a great amount of pleasure may be derived from the growing of annuals alone. Sowing generally should be done at once, first raking the soil down to a fine condition and covering the seeds with fine soil, little or much, afterwards, according to requirements.

G. P. K.

NOTES AND REPLIES.

Arum Lilies in the open.—Would you kindly give me advice about my Arum Lilies? Having too many under glass, I want to grow them in the open. Is this possible without taking them in at all? I have seen splendid masses of them grown in the garden, and in flower in September or October. How am I to treat my plants to get this result?—LOUIS BARTON, Dundalk, Ireland.

[These plants can only be grown in the open in the more favoured parts of these islands, and then preferably in water. From your letter it appears you wish to grow them in the open garden, and unless you have proof of their success in your own immediate locality all you can do is to experiment with some of your surplus stock. In any case they would require a wet or moist, well-sheltered position, and a good deal of protection in winter. Submerged in water to a foot in depth they pass the winter fairly well, and flower during the summer. In your case you had better shake the plants out of the soil, divide them if necessary, and plant out at once, observing the hints given above. You say you have seen "splendid masses grown in the garden and in flower in September and October." You do not say whether they were permanent there or only temporary. If the former, and you are like circumstanced, you could not do better than copy it.]

Dividing Crown Imperials and Iris Kämpferi.—Can you tell me if I should divide my Crown Imperial roots this year? They are not flowering freely, and to my knowledge have not been divided for five years, also some of the clumps are producing variegated leaves. How often should Iris Kämpferi be divided?—J. L. NICHOLSON.

[The only safe guide as to how often the above-named plants require dividing is their behaviour in individual circumstances. No rule-of-thumb method can be laid down. Crown Imperials are impatient of frequent disturbance, and take some time to recover. As they are not flowering well and have been some time in the position, they may require replanting and new soil. They prefer a rich calcareous loam, and should be planted not less than 6 inches deep, manuring the ground well at some inches below the bulbs. July is the best time to transplant. The Iris question is answered above. If you can give us particulars of the size of the plants and their general behaviour, we may be able to advise you more definitely.]

The Mayflower (*Epigaea repens*).—In answer to "Surrey's" question respecting the failure or success of *Epigaea repens*, I think he has unconsciously given the answer, as he says: "In its own country acres of it may be seen in dry, sandy soil under Pine-trees." If after planting in peat it is covered with Pine needles during the winter the plant will grow through these and thrive and flower quite happily.

Among hardy annuals are many subjects which, if allowed space for proper development, continue to bloom for a very long period. Of these the *Godetias*, especially the double varieties, are a host in themselves. The same remark also applies to *Clarkias* of the *elegans* section, as the varieties salmon-scarlet, salmon, delicate pink, Snowball, and Firefly are all double flowered, and make an imposing display when well grown.

Convolvulus minor in two shades of blue, also of pink, is very effective when massed. *Linum grandiflorum rubrum* is also very fine when grown in a mass, and the same may be said of *Viscaria cardinalis* and a delicate pink-flowered variety which is also effective. The *Collinsias* are very free blooming and lasting, while *Saponaria Vaccaria*, with its pretty pink flowers, must not be omitted. This attains a height of about 2½ feet. *Dimorphotheca aurantiaca* and its hybrids are very showy and telling, while the *Eschscholtzias* furnish various shades of colour, varying from ruby-red, rose, pink, orange, to yellow and white. The improved

In the same way, those who have failed with *Linnaea borealis* have achieved success by adopting the above plan.—C. P.

—“Surrey,” page 189, asks about *Epigaea repens*. It does well in Bucks in peat among small Heaths and *Rhododendrons*. It is in a dry situation, and forms a dense mass. Last year a great deal of it was divided up and spread about, and has become firmly established. There is no doubt it likes a bit of shade, though not too much, I think. The last gale did a lot of damage, forty-two trees down in all, some of them fine specimens, though, luckily, none in what I call really important situations.—MAURICE YORKE.

—In the early spring of 1905 I planted three good roots. A hole 3 feet in diameter and 18 inches deep was dug out on the north side of a very large Douglas Fir, between the huge roots which run here on the surface. The soil was a mixture of sandy peat and Fir needles, and some charcoal was added. The plant increased very rapidly, and in a few years covered the whole bed, and flowered freely from February to April. In 1914 I was foolish enough to remake the bed, and nearly all the plants died. I have now three strong tufts, which are running freely, but do not think they will flower this season. The natural soil where the *Epigaea* succeeded is little else but great boulders and chips of slate or granite. It is very dry in the summer, but there is a heavy rainfall in the autumn and winter.—E. C. BUXTON, *Coed Derw, Bettws-y-Coed*.

Germination of old seed.—I quite agree with all that “E. H.” says at page 136. Those who have had much to do with seeds know that much depends on the harvesting and storing. The seeds of many are just as good the second year as the first, if they have been well stored. Some years ago a friend in the seed trade assured me that he preferred for his own use Beet seed two years old. I tried it, and now I always use this in preference to new seed. This spring I tried some of this age in a pot put into a dung frame, and found 90 per cent. grew. In the autumn, having seed of a special stock two and three years old of *Polyanthus*, which I wanted to breed, I sowed it, and found 90 per cent. grew. The two-year-old seed was only a week longer in coming up than new.—DORSET.

Herbaceous plants.—Many of these will be sufficiently advanced for the crowns to be thinned, an operation that should not be overlooked in old-established plants, for they mostly show far more growths than they can bring to perfection. The extent to which thinning may take place must be judged by the nature of the plant and its growth. No exact rule can be laid down for all, but the thinning should be ample, and, as a general rule, the best and strongest growths will be found around the outside of each clump. Vacant spaces in the herbaceous borders may be tastefully filled with choice annuals, and care should be taken to thin them sufficiently. Many people sow their seeds too thickly and injure the plants by delaying the thinning.

The Dyers's Chamomile (*Anthemis tinctoria*) grows about 18 inches high, and is excellent for a mixed border in any soil but stiff clay. It blooms for a long time in summer, its main defect being that at dusk or in the late afternoon the ray petals hang down just as in a half-closed umbrella. It flowers for a long period, and the succession is prolonged if the decayed blooms are picked off as they go past their best. The typical flower is of a golden-yellow, but several varieties have been raised, including *A. t. Kelwayi*, with larger and deeper-yellow flowers, and *A. t. pallida*, whose blooms are of a sulphur-yellow. The white variety, *A. t. alba*, is not so desirable as the others.—ESS.

The Scarlet Twin-flower (*Bravo geminiflora*).—Where *Tigridias* succeed in the open, a trial ought to be given to the equally charming *Bravo geminiflora*, one of the finest of the summer-flowering bulbous plants. The flowers, resembling somewhat those of the *Tritonia*, are, as its name implies, arranged in pairs, often to the number of thirty, along the slender stem, and are of a good shade of coral-pink. *B. geminiflora* must have a sunny exposure on a warm border, and, to make quite safe, ought to be protected in winter.—KIRK.

Crocus biflorus Bowles's Blue.—This is a charming blue variety of the valuable *Crocus biflorus*. It is much deeper than any Welden form that I know. Nothing in the illustrations in Maw's wonderful “Monograph” approaches this variety in depth of colour-tone.—S. ARNOTT.

GARDEN FOOD.

CHINESE CABBAGE.

THE following from *The Rural New-Yorker* issue of January 1st, 1916 :—

This has peculiar cylindrical heads, rather suggestive of Swiss Chard or Cos Lettuce. It is a Fall Cabbage, which should not be sown in spring, or it will go to seed. Sow in July in rows; begin manuring heavily when 4 inches high. Harvest after first light frost. By cutting off all green leaf tips it can be cooked without penetrating Cabbage odour. It is very tender and mild-flavoured. As served in soups in some of the Chinese restaurants here this Cabbage appears very slightly cooked, being chopped and added to the soup just before serving. Poultry seem extremely fond of this Cabbage—

will, I think, answer your query about the “Celery Cabbage.” I have grown the *Pai-tsai* a number of years. It is very easy of culture, but our New Jersey summers are, I think, too dry and hot for it, as a rule, and it becomes tough. It is also a favourite prey of the flea-beetles in a dry season. Earlier importations of the seed were evidently of a poorer type, the mid-rib being less developed and the leaf flimsier in structure. The Chinese gardeners in this country have evidently had the better form, as I have often seen it on sale in Dayers Street, in New York's Chinatown, and at Chinese restaurants in the same quarter. The Chinese cooks make a very rich chicken soup, to which chopped *Pai-tsai* is added just as it is served, so that the Cabbage is crisp and succulent, and without the rank flavour of ordinary long-boiled Cabbage.

That recipe for cold slaw or Cabbage salad sounds a little vague, for usually pepper, salt, sugar, and butter are added to this boiled dressing of eggs and vinegar. It is not a favourite with me; I prefer hard white Cabbage, crisped in ice-water, shredded fine, to which may be added shredded Onion, chopped Chives, Celery, or green Sweet Peppers (Chillies), served with French dressing. It is excellent with fish, and is very often served with fried oysters. My Jersey Dutch neighbours also make hot slaw (cole or cold slaw is a Dutch invention), which is shredded Cabbage heated in the vinegar before the egg dressing is added.

EMILY TAPLIN ROYLE.

Maywood, New Jersey.

—Reference may be made, as to this, to “*Le Potager d'un Curieux*” at p. 464, seq., where there is a long account of the *Pé-tsai* and also of the *Pak-choi*. They are also described in “*The Vegetable Garden*” at pp. 170-171. The seed of *Pé-tsai* can be obtained from Messrs. Vilmorin-Andrieux et Cie., of Paris.—T. V. ROSTON, *Godalming*.

COOKING VEGETABLES.

YEAR in, year out, the average wife continues to cook the fresh English vegetables in the same old way; no change, no variety. We are put to shame by the tireless little Belgian wife, whose vegetables are a joy to look upon by the time they reach the table. Here are some of her favourite recipes :—

COATED LEEKS.—Remove the tops and outside leaves from the Leeks. Wash them thoroughly and leave to soak in cold, well salted water for at least ten minutes. Tie the Leeks in bundles, and put into a white-lined pan, with boiling salted water to cover. When quite tender, drain thoroughly. Have ready one large slab of toast, put this in the bottom of the hot vegetable dish, range the Leeks in a

neat pile, and coat with the following sauce: $\frac{1}{2}$ oz. of flour, $\frac{1}{2}$ oz. of butter, $\frac{1}{2}$ pint of milk and water mixed, or the water in which the Leeks have been boiled. Melt the butter, add the flour, stirring it well in away from the heat, add the liquid, and stir well until the sauce thickens, and use. When vegetables have been thoroughly cleaned and washed, the water in which they have been boiled can always be used for making a coating sauce; of course, milk makes the sauce a whiter colour, but otherwise the liquor can be substituted with excellent results.

BAKED PARSNIPS AND TURNIPS.—We get so used to these two vegetables coming to table boiled, few of us know how delicious they can be when cooked in this way. Peel and scrape the Turnips, and cut into thick slices, then boil them in water until nearly done, drain the water off, put the slices in a baking-tray or a fireproof dish, and pour over a little milk. Put a few flakes of butter or dripping on the Turnips, sprinkle with a little finely chopped Parsley and seasoning of salt and pepper. Bake until the Turnip is quite tender, dish and serve at once. Parsnips should be par-boiled in the same way, and baked till brown in a tin with a little melted dripping or cooking butter at the bottom. If the joint is being baked in the oven, the Parsnips can be cooked underneath the meat trivet. This will give them a delicious flavour and will entirely alter the peculiar sweet taste of this vegetable.

—*Mother and Home.*

NOTES AND REPLIES.

The “Spice” Apple.—I hope your readers will not call this very interesting Apple the “Spice,” a name which has no meaning or use. The right name for it is the *D'Arcy* Apple. There are other names, such as *Baddow Pippin*—none so good as the *D'Arcy* Apple.—W.

Strawberry St. Fiacre.—One of the best of the recently-introduced autumn fruited is undoubtedly *St. Fiacre*. It is a heavy cropper. The berries, more resembling those of *Royal Sovereign* in size, are of good flavour. The colour is bright and the fruits are borne freely. It is undoubtedly the finest of all the autumn fruited. Now is a good time to plant new beds. The plant is by no means a gross grower, but I would advise a good root-run and at least 18 inches between the rows to allow the sun to get at the fruit. I prefer a sloping south border for the latest supply. Last season it was so good in late October that I made a note of it and found it valuable when potted up for late fruiting. Grown on shelves in 5-inch pots, and not over-cropped, the fruits are excellent.—C. R.

An Eastern way of preserving Apricots.

—In the neighbourhood of Damascus Apricots are grown in large quantities, and much of this fruit is preserved for future use by a method which has been known to the inhabitants from ancient times. The fruit is boiled down, without the addition of sugar, to a thickish pulp. It is then spread out on hot stone plates to bake, or when such are not available it is baked in an oven. This process converts it into a paste, which will keep any length of time. Being drawn out into long, thin thongs, it finds its way in that form to the market, where it is known under the name of “*amardin*.” Some has been kept for fifteen years in good condition. It is easily carried about and takes up very little room. During the coming fruit season, now that sugar as well as bottles for preserving are very scarce and dear, this old method of preserving our fruit might be tried by some of our housekeepers, who are fond of experimenting. It is said that Apples, Plums, and Pears lend themselves to the treatment. The “*amardin*” can be eaten as a sweetmeat, and being absolutely pure it is better and healthier than most; or it may, with the addition of water and, if desired, a little sugar, be boiled up again for the table, and can then be eaten as an adjunct to bread and butter, puddings, etc.

TREES AND SHRUBS.

LOMATIA FERRUGINEA.

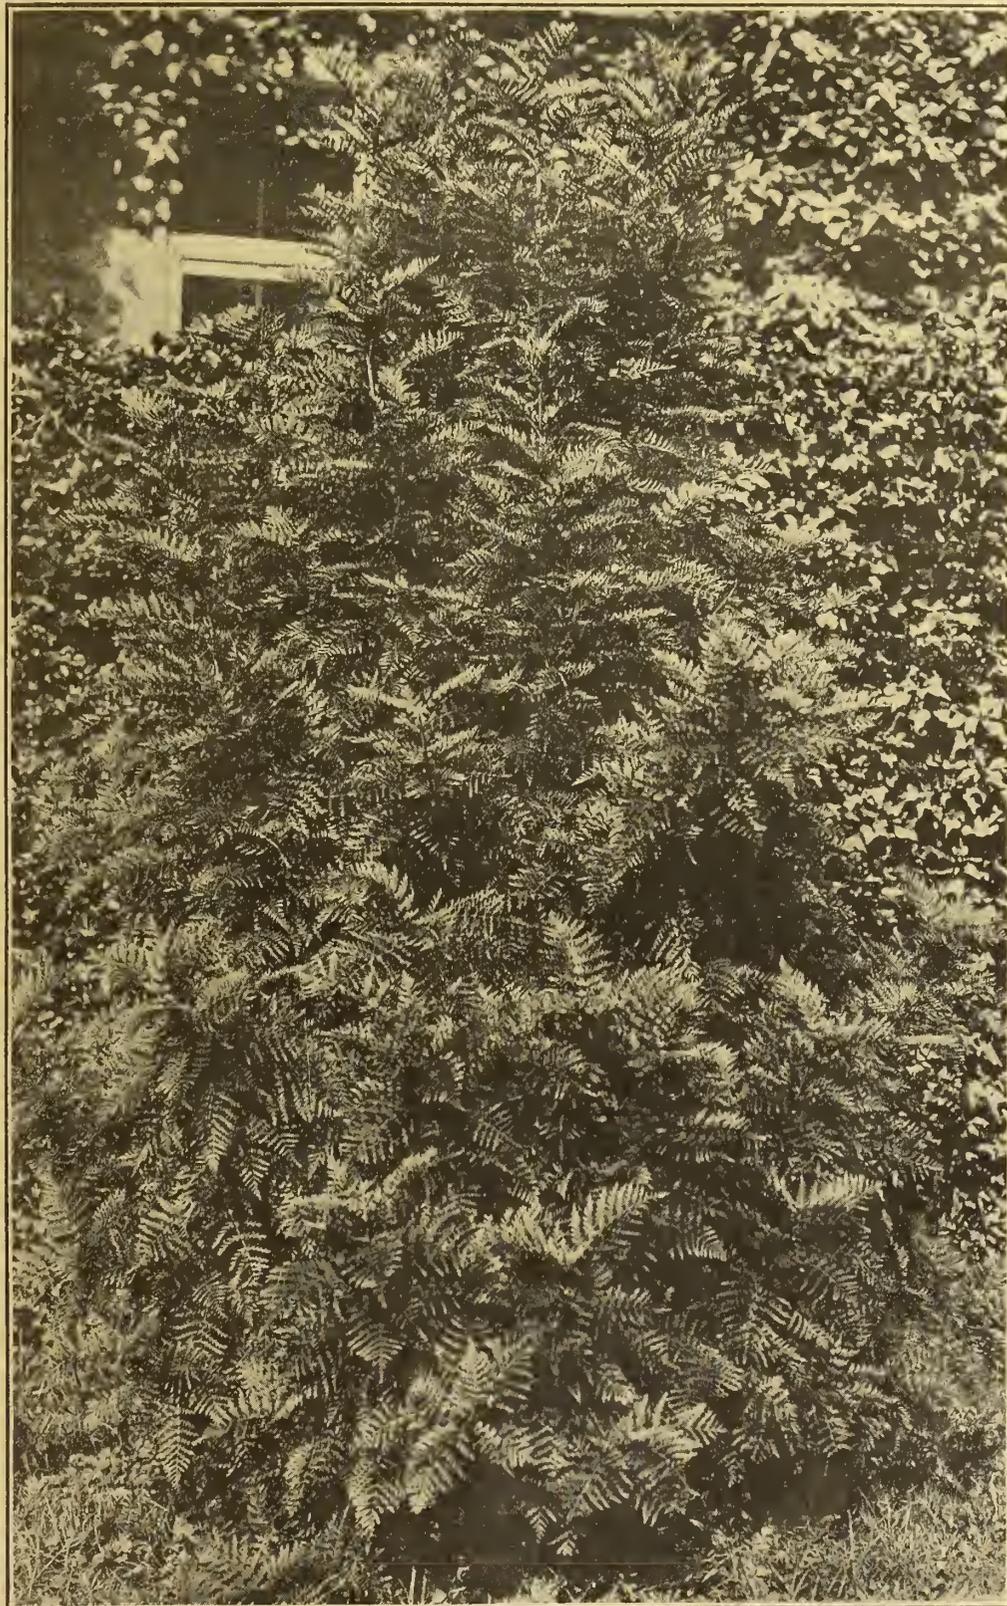

This is a handsome and graceful Chilean shrub of Fern-like character. Its leaves are very dark green on the upperside and

to sun and air, though protected from wind. It may be increased by layering.
Cork. R. H. B.

THE CRAB APPLES.

IN horticultural and botanical literature the Crab Apples are often referred to as

Apple native of this country—as *M. angustifolia*, *M. fusca*, *M. glaucescens*, *M. coronaria*, *M. ioensis* and its form, known as the Bechtel Crab, which has large and fragrant double pink flowers that look like roses and excite the interest and admiration of all beholders. The American Crab

Lomatia ferruginea at Ashbourne, Glounthaune, Co. Cork.

the red and yellow flowers are produced upon the hard wood, and therefore somewhat concealed from view by the dense foliage. When small it is susceptible to frost, but as it ages its resisting power to cold is much greater. It grows rapidly in any light soil, and must be fully exposed

“*Pyrus* (something),” but nowadays it is customary to speak of them under the generic title of *Malus* and to restrict that of *Pyrus* to the Pears, and this is followed here. My intention is to tell here of the Crab Apples of eastern Asia, but there are also several very beautiful species of Crab

Apples blossom later than their Asiatic allies, and both groups deserve the widest recognition. The Siberian, *MALUS BACCATA*, is the oldest known but one of the Asiatic Crab Apples, having been introduced to Europe in 1784. It is a tree 30 feet to 40 feet high, with stout,

spreading branches and slender branchlets which form a broad, rounded, or more or less oval crown. The flowers are pure white, delightfully fragrant, and profusely borne in clusters; the fruits small, yellowish or yellow-brown. This tree is widely dispersed in the cold northern parts of eastern Siberia, and extends southward into Mongolia, Mandshuria, and extreme northern China. It is the most northern of its class and the hardiest of all species of *Malus*, and for this reason ought to be used in the colder parts of this country as a stock for the common Apple. In the littoral regions of north-eastern Siberia, in Korea, and in northern Japan this species is represented by its variety *mandshurica*, which differs in certain technical points and has scarlet fruit. In Korea there is a form (*Jacki*) which has handsome, relatively large dark red fruit. Under cultivation numerous hybrids between *Malus baccata* and the common Apple and other species have arisen, and all of these are ornamental in flower and exceedingly beautiful in fruit. They are known collectively as Siberian Crab Apples, but many of the varieties have received distinctive names. The oldest known is the Chinese

M. SPECTABILIS, which was introduced from Canton to England in 1780. It is cultivated in the Imperial gardens at Peking and elsewhere in China, but has not yet been reported in a wild state. It is a small tree 20 feet to 30 feet high, with a narrow vase-shaped crown made up of numerous rigid ascending branches and short branchlets. The flowers are pale pink, more or less semi-double and fragrant, and the fruits are yellow, nearly globose, and about $\frac{3}{4}$ inch in diameter. The habit is rather stiff, but this old denizen of gardens with its wealth of clustered blossoms is strikingly beautiful. A lovely Crab Apple bearing in season its pale pink flowers in the utmost profusion is

M. SCHEIDECKERI. This is also a small tree, loosely pyramidal in habit and of hybrid origin, one of its parents being assumed to be *M. spectabilis*. The next species to make its debut in this country is the celebrated Parkman Crab.

M. HALLIANA, which was sent from Japan to the United States by Dr. G. R. Hall in 1861, and first cultivated by Francis Parkman, the historian, in his garden on the shores of Jamaica Pond, Boston, Mass. This is a tree-like shrub with a broad, bushy crown and twiggy branchlets and rather thick, dark green leaves deeply tinged with bronze colour where they unfold. The flowers, each on a long, slender stalk, are borne in clusters and are bright rose in colour, and these are followed by Pea-like dark greenish-red fruits which ripen very late in the fall. In a family so beautiful as the Crab Apple there is room for divergence of opinion as to which is the finest, but many (of which I am one) consider the Parkman Crab the most winsome of all the Asiatic species. The type has flowers single or nearly so, but there is a form (*Parkmani*) which has double or semi-double flowers. This lovely plant has long been a favourite in the gardens of the flower-loving Japanese, who call it the "Kaido," but like many plants cultivated in Japan it is of Chinese origin. In 1904 I had the pleasure of discovering it growing wild in thickets on the frontier of western China and Tibet, and collected seeds from which plants have been successfully raised. A very desirable plant is

M. ATROSANGUINEA, which is a hybrid presumably between *M. Halliana* and *M. Sieboldi*. It is a broad shrub growing 10 feet or more high, with thin spreading and arching branches and rose-pink

flowers. Perhaps the best known of these Asiatic Crab Apples is

M. FLORIBUNDA, which was introduced about 1853 by von Siebold to Leiden in Holland, yet its native country remains unknown to this day. Present-day Japanese botanists seem unacquainted with this plant, and both they and Japanese nurserymen confuse it with the Parkman Crab, and during my trip in Japan I never met with it. However, since our gardens are in fortunate possession of it we can waive the more academic question of its habitat. It is a broad, round-topped, tree-like shrub sometimes 25 feet high, and as much in diameter, with slender, arching, and pendent branchlets. The clustered flowers are pure white when expanded and bright rose colour in bud, and as they open in succession the contrast is singularly beautiful. The fruit is about the size of a Pea, yellowish or yellow-brown and long persistent, but not attractive except to birds, which appear especially fond of it. In gardens all the species of *Malus* hybridise freely and the group offers a field of immense interest to those who will breed and select the offspring. Some years ago there appeared in the Arnold Arboretum among a batch of presumed seedlings of *M. floribunda* a very distinct plant which has been named

M. ARNOLDIANA. It is probably a hybrid between *M. floribunda* and *M. baccata*, but whatever its origin it is certainly one of the most lovely of all Crab Apples. The habit is similar to that of *M. floribunda*, but the flowers, though of the same colour, are one-half larger, and the fruit, too, is much bigger. A friend of mine who lives at Winchester, Mass., has a fine specimen of this hybrid growing under the lee of his house, and no one has yet been able to persuade him that there is any other Crab Apple which approximates to this in beauty. At the same time as Siebold introduced *M. floribunda* he also introduced another Crab Apple, *M. Sieboldi*, better known as

M. TORINGO. This is a low, dense shrub of sprawling habit, with lobed leaves, small flowers, white tinged with rose in colour and small yellow fruit. It is really a scrubby form of a species widely distributed in Japan and horticulturally inferior to its real type, now known as var. *arborescens*, which is a small tree with ascending and spreading branches, twiggy branchlets, and fruit yellow or red on different individuals. Another variety (*calocarpa*), raised from seeds sent in 1890 to the Arnold Arboretum from Japan by Dr. William Sturgis Bigelow, has handsome bright red fruits $\frac{1}{2}$ inch in diameter and is, in fruit, the most strikingly beautiful of all Crab Apples. Differing from the tree form of *M. Sieboldi* only in certain technical matters is

M. ZUMI, which was introduced to cultivation by Professor C. S. Sargent, who collected seeds in Japan in 1892. This, too, is a very desirable small tree with fragrant white flowers and small yellow or red fruits. It is common on the slopes of Mount Fuji and on the shores of Lake Chuzenji in the Nikko region.

Most of the orchard fruits grown in the countries of the Far East have been obtained by long cultivation from species indigenous to China, and have not common origin with the same kinds of fruits cultivated in this country and in Europe. The Apple of that region is an example. It is only very recently that science has become acquainted with the source of the Apple of China and Japan, although under various names it has been in cultivation in the Occident for some sixty years. This Apple,

M. PRUNIFOLIA VAR. *RINKI*, grows wild in the mountainous parts of central China, where I was fortunate enough to discover it in the spring of 1901, and later secured seeds which resulted in its successful introduction to our gardens. Previous to this discovery it was known only from plants cultivated in Japan, and by most botanists was considered a very doubtful plant. From Japan it was introduced to Europe about 1854, and distributed by von Siebold as *Malus Ringo*. In habit this species resembles the common Apple, but its leaves are rather different, the flower-stalks are much longer, and the fruit is not impressed at the summit. As a fruit-tree the Chinese Apple is cultivated in central and western China, from river-level, where the climate is very warm, to altitudes of 9,500 feet in the more mountainous parts, where a severe climate obtains. In northern China and Korea it is cultivated sparingly over a wide area. The fruit is small, seldom more than $1\frac{1}{4}$ inches in diameter and slightly longer than broad, of a pleasant bitter-sweet flavour, and varies in colour from greenish to greenish-yellow, and is rosy on one side. Occasionally it is nearly all red. Formerly this Chinese Apple was cultivated in Japan for its fruit, but since the introduction of varieties of the European Apple its cultivation as a fruit-tree has been discontinued.

There are other species of much merit and beauty, and several new ones whose value we do not fully know, but there is one so distinct in habit and with a field of usefulness so peculiarly its own that it must not be omitted even in this incomplete enumeration, and that is

M. SARGENTI. This species is of dwarf stature, the branches rigid and spreading, and the lower ones flat on the ground, and is eminently suitable for covering slopes and banks. The flowers in umbellate clusters are saucer-shaped, round, and of the purest white, and these are followed by masses of wine-coloured fruit which is covered with a slight bloom. In its habit, its flowers, and in its fruit it is very distinct from all other species. We owe this valuable addition to Professor C. S. Sargent, who discovered it in fruit and sent seeds in 1892 from near Mororan in Hokkaido, Japan.

In this group of Asiatic Crab Apples there are trees for the avenue, park, or garden, shrubs for the lawn or border, and others suitable for slopes and banks—all absolutely hardy in the coldest parts of New England, and each and every one may be depended upon to produce every spring a wealth of blossoms in veritable cascades. The plants grow quickly in good loamy soil, and many of them begin to flower and produce fruit when only a few years old.—E. H. Wilson in *The Garden Magazine*.

NOTES AND REPLIES.

Pruning *Pyrus japonica* (*Inquirer*):—*Pyrus japonica* will always flower in a far more satisfactory manner when allowed to grow naturally than it will if closely pruned. Such being the case, the plant should be cut back only as far as is absolutely necessary to keep it within the assigned bounds. No pruning to particular eyes or buds is required in this case, the main consideration being the space at disposal. At the same time any old or exhausted shoots should be cut out, as by so doing the young, clean growth upon which depends a good deal of the future display of bloom is greatly encouraged. A good time for carrying this out is directly the flowering season is over, as the specimen has then a long growing period before it.

ROOM AND WINDOW.**CROCUS PURPUREUS
GRANDIFLORUS.**

Among the many Crocuses I have grown—and I have tried a good many—this, among the purples, is the finest, and it has the added merit of not being rare, but a rather cheap and neglected kind. The purple is splendid, especially in the buds, and it has the virtue of keeping its colour in the evening. W.

INDOOR PLANTS.**NOTES ON GREENHOUSE PLANTS.**

CHOROZEMA HENDERSONI.—The amateur who would like something out of the com-

This species is of lax habit, making shoots under good culture some 18 inches long, which make it useful, and as it must annually be pruned back rather hard to keep it within bounds, taking long sprays for decoration is not injurious. A compost of loam and peat in equal parts best suits it, adding a little coarse white sand. Repotting should be done when the young shoots are about $\frac{1}{2}$ inch long, and watering must be very carefully done until growth is being freely made. From the end of June until the beginning of September this *Chorozema*, like nearly all hard-wooded greenhouse plants, is best in the open air. Full exposure to the air gives substance to the wood.

GREVILLEA ROSMARINIFOLIA.—I wonder if this is the same as *G. angustifolia* men-

plants of the old ball of fibre becoming dry after repotting, in which case it may remain so for a time, the water given passing away through the new compost. Although repotting *Azaleas* annually is practised by those who wish to obtain the best results, it is by no means necessary to do so, as they can be maintained in health for several years without change of soil. It is simply a matter of giving weak liquid manure occasionally.

ECHEVERIA RETUSA.—This, like all members of the family, requires a maximum of sunshine when making its growth. Where the black weevil abounds it is liable to be badly attacked, the plants collapsing just as they are coming into bloom. Where this is the case the only way is to shake the soil away from the

Crocus purpureus grandiflorus.

mon in greenhouse plants should grow this. It belongs to the so-called hard-wooded class of greenhouse plants reputedly of rather difficult culture, and which, therefore, are shunned by those who have had to pick up their knowledge as best they could. The majority of them require the hand of the expert, but this *Chorozema* is as easily grown as a *Cyclamen* or *Primula*. I doubt if its value is fully appreciated by professional gardeners, for, unlike hard-wooded plants generally, it is very useful for cutting, and can be gently forced, whereas this class of greenhouse plant is very impatient of artificial warmth. The natural blooming time of this *Chorozema* is in May, but this year I have been using, early in April, sprays of it cut from plants that have been wintered in a warm house.

tioned in a recent issue of this paper. The plant I grew many years ago under the above-mentioned name did not exceed 1 foot in height, was very compact, and free flowering. I remember having a number of plants in my charge in my young days, but was told it had another name. I cannot find *G. rosmarinifolia* in any trade list. Perhaps some of your readers can afford some information in the matter. It is a charming little species not at all difficult to grow.

REPOTTING AZALEAS.—The directions given in a recent issue of *GARDENING ILLUSTRATED* are very good, but there is one detail that I have always considered as important. This consists in piercing the old ball with an iron skewer from the top down to the drainage. There is always a danger with very root-bound

roots in the latter end of June, wash away every particle of soil, and repot in fresh compost. In this way the eggs are got rid of. BYFLEET.

Statiche profusa.—Although strictly a greenhouse plant, a little moist heat proves beneficial when the plants are making new growth. A batch of plants which had seen a good deal of service during the past year, and were in need of a restorative, have been placed in a vinery, where the warmth and moisture are suiting them, as is evidenced by the amount of new growth they are making. Flowers will be suppressed until the plants have completely recovered. Then they will be allowed to push up their inflorescences and be placed in a greenhouse. On account of the length of time

the flowers last in good condition it is a first rate subject for room decoration. Once the pots are well filled with roots the plants require to be well watered.—G. P. K.

THE WINTER-FLOWERING BEGONIAS.

THESE Begonias have few equals, especially when we consider the bright and varied tints of their large flowers. B. Gloire de Lorraine, a reputed hybrid between B. Socotrana and B. Dregei, and its allies, such as Turnford Hall, are well known, and where these are grown there is no reason why some of those mentioned below should not be included. If I had to confine myself to one Begonia for winter work I should choose B. Elatior, a semi-double flower of a rich rosy-carmine shade. It is an easy plant to grow, very free-flowering, and an excellent subject for dwelling-house decoration, the colour of the blooms being extremely effective under artificial light. Ensign is another semi-double, colour light earmine toned with scarlet. The Gem is a fine rosy-red and well adapted for small pots. In striking contrast to these we have Exquisite (pink and white), Fascination (a compact-growing plant with bright orange-salmon flowers), Emita (orange-scarlet), and Optima, bearing a profusion of pale orange blooms which stand well away from the foliage. All the above were raised by the late firm of Messrs. J. Veitch and Sons, but Messrs. Clibran, of Altrincham, have also introduced numerous hybrids of a high standard, as Scarlet Beauty, Eclipse (salmon-red), Altrincham Pink, Lucy Clibran (orange suffused with rose), Splendour (reddish-scarlet), and Apricot. There are many more, but it would be useless to continue the list. A good plan is to visit a nursery where these plants are made a speciality of, or one of the London shows, then a selection could be made to suit each individual taste.

CULTURE.—When dealing with this group of Begonia the grower should bear in mind that they were raised from B. socotrana; a pretty pink-flowered species with fibrous roots, and varieties of the popular tuberous-rooted section. If this is done the difficulty of giving the plants a partial rest will be almost overcome. During the late autumn and winter months these Begonias will be in flower, and when they pass this stage the resting season begins, and continues until the end of March. At this time they require careful watering, and the temperature ought not to fall below 50 degs. Fahr. We should aim at giving just enough water to keep the stems and foliage in a healthy state. When growth commences, the plants will require repotting in a mixture of fibrous loam, leaf-mould, and sand, the first being the chief ingredient. The pots should be filled to one-fourth of their depth with drainage, over which is placed a thin layer of rough soil to secure a free outlet for water. Hard potting is not advised. To maintain a clean, healthy, and robust stock of winter-flowering Begonias it is advisable to strike a few cuttings each year. These may be taken at any time between April and August, the former month for preference, then some nice plants that will flower in November are obtained. Cuttings are made from the young shoots which form in the axils of the leaves. Make them in the usual way by cutting off the lower leaves and severing the stem immediately below a joint. Place them either singly or several around the edge of a small pot filled with sandy soil, and then stand them in a propagating-case or small frame where the tempera-

ture does not fall below 65 degs. Fahr. When they have formed roots they should be potted on in the same kind of compost as mentioned above until they are in pots 5 inches in diameter. Older plants, such as those rooted the previous year, will require pots a size larger. Throughout the growing season the temperature should be from 60 degs. to 65 degs., and to keep the atmosphere slightly moist the syringe should be occasionally used between the pots. Shade from strong sunlight and admit air judiciously at all times. Overhead spraying is not recommended to any great extent, and it ought only to be practised on bright days and early enough for the foliage to become dry before sunset.

INSECT PESTS.—The principal insect pests are thrips and a mite which causes the foliage to assume a rusty appearance. Both can be destroyed by vaporising with XI All or any similar fumigant about every three weeks. Small plants could be dipped in a solution of any reliable insecticide. No gardener or amateur who has the glass accommodation and is fairly successful with the Lorraine section need fear taking up the cultivation of these charming Begonias. T. W. B.

NOTES AND REPLIES.

Soil for India-rubber-plant.—I have two India-rubber-plants which want potting very badly. They are in much too small pots, and their roots are exposed. Would you be so kind as to tell me what sort of soil they require and if manure or leaf-mould should be used? Should the soil be rammed down hard or should they be loosely potted?—L. BROOKE.

[A suitable soil for the India-rubber plant may be made up of two parts loam to one part of peat, and sufficient silver sand to keep it porous. The potting compost must be pressed down moderately firm.]

Soil for Arum Lilies.—Would you kindly tell me what kind of soil Arum Lilies require, and if they should be potted tightly or loosely?—L. BROOKE.

[The Arum Lily needs a rich soil, say two-thirds good loam and one-third well-decayed cow-manure free from insects, with a sprinkling of sand. If no manure such as above indicated is available, leaf-mould may be substituted for it, and, failing that, peat. The soil should be pressed down moderately firm. Should peat be used, stimulants of some kind must be given more frequently than when there is a mixture of manure in the potting compost.]

Thunbergias.—The Thunbergias have, perhaps, become less popular than was at one time the case. The annual variety, T. alata—familiarily known as Black-eyed Susan—is a charming climbing plant with slender stems and numerous buff-coloured flowers, each having a black centre. T. a. alba is identical in habit, but with white blooms, and is less effective than the former. Both may be raised in heat from seeds sown now, and will be useful throughout summer and autumn in the greenhouse. A distinct race is the hard-wooded Thunbergias, which require stove heat and are useful roof plants. They include T. laurifolia, with pale-blue flowers with a white throat; T. Harrisii, a vigorous grower with bold racemes of purplish-blue blossoms with yellow throat; and T. fragrans, with small, dark-green leaves and pure-white tubular flowers. The specific name of fragrans is rather a mistake, for the blooms are destitute of fragrance. This variety flowers during the winter, the others in summer and autumn. T. natalensis succeeds under greenhouse cultivation. The hard-wooded Thunbergias require a good yellow loam, to which may be added a proportion of peat, a little well-decayed manure, and a

sufficiency of sand. Both the annual and perennial varieties being liable to attacks of red-spider, frequent syringing is necessary.—W. McG., *Balmac*.

Hæmanthus Katherinæ.—A few of the Hæmanthus require stove heat, but the variety under notice does well in the greenhouse. It is by no means difficult to cultivate, and succeeds well in a good loam with a fair proportion of leaf-mould and coarse sand. When established in suitably-sized pots, like many other bulbous plants, Hæmanthus are best left undisturbed for a series of years. After flowering, which is usually in July or August, the plants must have gradually diminishing supplies of water until the foliage ripens off. Then they may be kept quite dry until growth is again visible; at all times, so far as possible, being fully exposed to the sun.—KIRK.

FROM THE FIRING LINE.

My son, Philip Edward Moon, left England for the front on May 1st, 1915, and between that date and a few weeks ago, when he came home on his first leave, had collected the following plants, all found, if not actually in the firing line, close to it. He went straight into the firing line, and his battalion acted as first support in the second attack at Festubert, and it was then that he found *Linaria minor* and *Sisymbrium Irio* (London Rocket) growing in the trenches, and close by *Galeopsis ladanum* and *Camelina sativa*. Later, when billeted close to Festubert, he found in a garden of a ruined cottage *Astrantia major*, his only loot! It was there that he saw a curious sight. A shell had burst in a dyke full of *Ranunculus aquatilis*, and shot a quantity of the plant on to the sides of the hole several feet above the level of the water, and there it was, growing quite happily as a small, compact, tufted plant, having lost its long feelers! He also found there *Galium palustre*.

In July his battalion was moved much further south, and in a village just behind the firing line he was much struck by *Malva sylvestris alba* growing amongst Crimson Rambler Roses. I remember he wrote home saying how beautiful the two were together, and suggesting we should try the effect in gardens here. At that time they, when out of the trenches, were billeted in the open fields, and often had shrapnel and bullets flying over them, but in spite of this and all the discomforts he found *Lychnis Githago*, *Lathyrus Aphaca*, *Vicia Cracca*, *Verbena officinalis*, *Orobanche minor*, *Centaurea Calcitrapa*, and also a very rare *Plantain*. Later they moved still further south, and were for a time near an old chateau, the gardens of which before the bombardment must have been very beautiful. One thing left growing in profusion amongst the ruins and debris was a pink *Petunia*, the flowers small but very pretty. In the trenches there the *Mint* (*Mentha arvensis*), scenting all round, and *Ajuga Chamæpitys* (Yellow Bugle), with its bright yellow flowers, were abundant. Growing on the parapet in the front trench he found *Cerastium arvense*. When they moved three miles back for a short time he found *Trifolium incarnatum*, *Althæa officinalis*, and *Adonis autumnalis*. It was in the early autumn, while they were relieving French troops, that he came across a "dug-out" covered with *Nasturtium*, and wondered what home-sick Frenchman had planted the seeds! He found the *Opium Poppy* seemingly growing wild, but thought probably it was an escape from some garden. E. A. Moon.

VEGETABLES.

TOMATOES FOR AMATEURS.

I HAVE grown Tomatoes both under glass and in the open air for more than thirty years, and during that time have found it necessary to grow them in fresh soil under glass to obtain the best results year after year, and to mix fresh soil with the old where the plants have been grown in the same place outside for a number of years. Rarely do plants fail to yield a good average crop when grown under glass. Outside—in the midlands and southern counties—my experience is that very satisfactory crops result three years out of five, and occasionally very heavy crops are obtained. Some varieties are much more satisfactory for outdoor culture than others, and there has been a vast improvement in the strains for indoor culture during the past few years. Seeds or young plants should be at once procured. Any light place under glass, with abundance of fresh air during the summer is suitable if the plants are grown in good loam made moderately firm. If only a few are to be grown in the open air, place them in small pots from the seed-pans or pots, and again repot them before planting them out the first week in June. If a big batch of plants is being dealt with, then raise them in boxes, transferring when strong enough and well hardened off to a bed in a cold-frame, and finally to their fruiting quarters. They must not suffer any check, as time is so valuable. When transferring the young plants to the boxes put them 3 inches apart in 3 inches of good loam and leaf soil mixed, on a layer of rotted manure. From the boxes shift the plants to beds in cold-frames, and treat them in the same way, but provide a bed of soil 4 inches deep on a layer of manure 2 inches deep, and put the plants 7 inches apart. While in the early stages of growth keep the plants on a stage or a shelf near the glass and afford them a little heat. If grown in warm pits, cover every night till the middle of May, but ventilate always when the weather is fine during the day, removing the lights in the day-time, too, to harden the plants during the last half of May. Ordinary soil in open borders should be enriched with rotted manure in the meantime and made firm. Put out the plants 18 inches apart. Tomatoes may be grown in quite open beds and trained, single-stemmed, to upright stakes. G. G. B.

THE HARDINESS OF CELERY.

At p. 9, January 1st, the question is asked as to the protection of Celery. It is well known that too early earthing up is frequently the cause of premature decay. My note does not concern Celery grown for exhibition, but that for home use. I do not favour the huge sticks one sees exhibited and the rich culture given. Such huge heads do not keep. As "A." rightly remarks, Celery given rich food is more subject to decay. I never, after planting out, gave late Celery other than salt and soot, both of these being of great value; also keeping the plants free from slugs, which often sadly disfigure the heads. "A." gives an excellent method of protecting, but even then there must be sound plants and quite free of decay, or the covers will be of little value. Celery grown by the method detailed below is of no use to those who want huge heads several feet in length. I always fight shy of the giant varieties for keeping; indeed, in many instances size is obtained at the loss of quality. We do not see large quantities of these huge growths exhibited after the autumn shows.

Many years ago I had to provide Celery every day in the year (if possible), and at the start I admit I had considerable losses, and though great care was exercised in the moulding up I had to adopt other measures. Often the soil is at fault, as, if of a close, heavy nature or clayey, it is most difficult to arrest decay, and this means much labour to make it suitable. The plants are often much weakened by too early sowing, by sowing in strong heat, by overcrowding in the seed-boxes, and delay in planting out.

For late supplies—and by this I mean for use from December to May—I would advise sowing on an open south border in rich, light soil. The seeds must be sown thinly, as there is no pricking off. The seedlings, when a few inches high, are lifted with a ball and transferred direct to their permanent quarters. Though the seedlings treated thus are very small, it is surprising how quickly they go away. In Celery thus treated there is no decay of the centre and an absence of pithy stalks, which are not so large I admit. I think it a gain if one can obtain a sweet, nutty, solid growth. The grower must largely depend upon certain varieties. There are some good forms to select from, and some of these, though not by any means of recent introduction, have proved to be the best keepers. These are the Incomparable Dwarf White and the Sandringham Dwarf White, both noted for their good quality and flavour. If red Celeries are liked I would advise A1, a dwarf, compact grower of excellent flavour and a splendid keeper, as it may be had good till quite late in the spring if grown as advised above. Kept late it loses its red markings. Of new varieties White Gem is an ideal Celery for keeping, dwarf, solid, and very hardy. I have kept these Celeries well into May by protecting with a few dry leaves or dried Bracken. As the days lengthen it is necessary to lift the plants, say in February or early March, with ample balls, and place in a cool, shady border. Do not omit moisture or there will be shrivelling of the leaf-stalks. Earthing-up, as "A." notes, is at times done too early, and also badly. With the dwarf Celeries mentioned above much less earthing-up was done than is often the case, my aim being to get a hardy plant. Celery grown for soups or flavouring and not earthed up in any way is quite hardy. I placed small quantities of soil in fine weather when the growth was nearly full-grown and at intervals of ten days or a fortnight. In the severe weather of 1895 my plants were but little injured, though a goodly portion of green leaf-stalk was exposed after the earthing up. A large number of plants grown for cooking in a wide but very shallow trench—six rows of plants in a trench—were not much the worse, the only protection being a covering of dry Bracken. W. F. K.

CAULIFLOWERS.

THE time for the second sowing of Cauliflowers being close at hand it may be well to give the reminder that so far as small gardens are concerned the small varieties should be selected, being, as a rule, superior in quality and more remunerative—that is, many more heads can be obtained from a given area and there is no waste. Some of the large Cauliflowers are of excellent quality, but others are decidedly strong. The small variety is known under many different names, but it is difficult to make any distinction except it may be there is one type a trifle closer and with leaves showing the protective character in a more pronounced form. Plants from the first sowing should be in small pots in a cold frame

by the time the second sowing is made, and yet another sowing can be made about the beginning of May. It is sometimes suggested that it is not advisable to make this late sowing of the small sorts owing to the fact that the plants are unable to stand a hot, dry time. This failing can be checked by planting in a fairly shady spot, preferably a west border, and after watering the plants well in, mulch with short manure or lawn Grass to keep in the moisture. All the sowings should be made as thinly as possible, as a thick plant sometimes means an attack of black-leg and the collapse of a large percentage. Powdered lime and wood ashes in the proportion of two to one scattered among the young plants will keep the enemy in check.

Cauliflowers, perhaps more than any member of the Cabbage family, are subject on some soils to clubbing, and it is very annoying to have a promising batch go off prematurely. If any danger from this is anticipated it is advisable before planting to dip root and stem into a stiff puddle of lime and soot, and if rapid growth from the planting can be maintained one is generally able to secure the crop. E. B. S.

Hardwick.

Useful early Lettuces.—With seed sowing somewhat delayed by the weather of late it will be necessary to make up lost time by sowing those kinds that give a quick return. For this purpose there will be considerable gain if one can in any way forward the crops at the start. The smaller, compact growers, as Tom Thumb and Commodore Nutt, are more suitable for earliest work. Both these produce nice, compact heads in a few weeks, and in addition they are of good quality. The two varieties named are, in my opinion, the earliest we have, and when given a little shelter they are most useful. Some are unable to give much frame shelter, but much may be done by sowing a pan or box of seed and covering with glass till the seedlings are growing freely. Placing a box of seed in a cold frame or under a hand-glass will do much to forward the crop. I have often sown a little seed at the foot of a south wall in March, and covered with mats at night or in cold weather, and gained considerable time. If one can, when planting out, give cloches or hand-glasses to a few of the best seedlings there is a gain of some weeks.—F. K.

Cabbage Christmas Drumhead.—For many years I have grown this small, useful Cabbage for the winter supply, and so far it has never failed. This season it has been excellent. The Christmas Drumhead Cabbage is very hardy, has a dwarf stem, a particularly close, compact growth, the heads medium-sized and of Drumhead shape. The quality is excellent and more like that of a good early spring Cabbage than anything else. In exposed gardens this is an ideal winter vegetable. I have found this Cabbage do well after Potatoes lifted early in August. Seed should be sown as early in July as possible; indeed, in the North I have sown this variety at midsummer. Owing to its close, compact growth it can be grown in a small space and, if possible, should be given an open quarter. I advise early planting (August), not allowing the seedlings to become drawn in the seed-bed. It is a good plan to plant in drills, so that, should the weather be dry, water can be given.—M.

Celery.—The plants intended for the main crop will be pricked out, from 3 inches to 6 inches apart, into skeleton frames as soon as ready. The soil should not be too rich. Shade for a few days during bright sunshine, and protect against frost and cold winds.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM APRIL 13TH.—*Magnolia stellata*, *M. conspicua*, single and double *Camellias*, *Azara microphylla*, *Prunus triloba*, the *Rosebud Cherry* (*Prunus pendula*), *Laurustinus* (various), *Ericas* (in variety), *Berberis* (in variety), the *Pearl-bush* (*Exochorda grandiflora*), *Daphnes* (in variety), *Andromeda polifolia* and others, *Spiraea arguta*, *Rubus spectabilis*, *Periwinkles*, *Cydonias* (in a variety of colours), *Skimmias*, *Phillyrea Vilmoriniana*, the *Chinese Quince*, *Rhododendron ciliatum*, *R. venustum*, *R. Jacksoni*, *R. racemosum*, *Elæagnus edulis*, *Forsythias*, *Osmanthus Delavayi*, the *Goat Willow* (*Salix caprea*), *Prunus Myrobalana*, *Sweet Gale* (*Myrica Gale*), *Blood-root* (*Sanguinaria canadensis*), *Primula rosea*, *P. cashmeriana*, *P. viscosa*, *P. Julia*, *Lithospermum rosmarinifolium*, *L. Heavenly Blue*, *Snowflake Gravetye Giant*, *Anemones* (in great variety), white and blue *Forget-me-nots*, *Honesty*, single and double *Arabis*, *Veronica filiformis*, *Anchusa myosotidiflora*, *Saxifrages* (various), *Caltha polypetala*, *C. palustris*, *Sweet Violets* (in great variety), *Snowdrops*, *Dog's-tooth Violets* (in variety), *Omphalodes verna* (blue and white), *Stylophorum diphyllum*, *Viola gracilis*, *Wallflowers*, *Narcissi* (numerous varieties), *Chionodoxas* (several kinds), *Hutchinsia alpina*, *Gentiana verna*, *G. acaulis excisa*, *Water Hawthorn* (*Aponogeton grandiflorum*), *Collomia grandiflora*, *Barrenwort* (*Epimedium*) (in variety), *Scillas* (in variety), *Crown Imperial* (*Fritillaria imperialis*) (in various colours), *Snake's-head* (*F. Meleagris*) (in many shades), *Jack-in-the-Green*, *Hyacinthus azureus*.

WORK OF THE WEEK.—Full advantage has been taken of the fine sunny days which have done so much to render the ground workable. The pruning of dwarf Roses has been finished, and the forking up and cleaning of the beds and borders are being pushed along at every opportunity. Further plantings of Tufted Pansies have been made. Should the weather remain favourable, some of the beds will be raked down to a fine surface, and choice dwarf annuals sown. Some of the dwarf blue annuals are extremely beautiful used in this way. Here and there open spaces are left in the Rose beds, or it may be across one corner. On these bare spaces the annuals are sown and allowed to intermingle with the Roses. A large quantity of Sweet Violets is grown outside, and as some of these have occupied the same position for three years a border raised above the ground level has been prepared, and the following varieties have been planted:—*La France*, *Admiral Avellan*, *California*, *The Czar*, *S. J. Josse*, and *Ascania* (the last a fine flower, almost equal in size to some of the Tufted Pansies and very fragrant). In a rather cooler and more shaded position, *Princess of Wales*, *Cyclops*, *Mrs. Schwartz*, and *Kaiser Wilhelm II.*, in separate groups, have been planted. In this latter position we hope to get late flowers. A few new Vines of the Teinturier group have been planted in the reserve garden as they were rather small. Over the bare places among the new plantations of Hepaticas flat stones have been laid to conserve moisture. A position has been prepared in a cool and shady lane for a group of Shortias. Rotted leaves, peat, sharp sand, and a little good loam formed the compost, and the position lying rather moist these slow-growing plants should do well. E. M. Sussex.

SOUTHERN COUNTIES.

Parsnips.—Much of the seed has perished outright, the succession of hard frosts experienced in March proving too much for it. This is the first occasion during the course of a long experience that seed of Parsnips has been killed by frost. The soil is in such good condition that it will not be necessary to sow elsewhere, and the plot will be resown at once.

French Beans.—Towards the end of the month the first sowing will be made on a warm border outdoors in short drills drawn 2 feet apart. If necessary, these can be quickly and conveniently protected. An early maturing or forcing variety is always selected for the first sowing. To succeed the foregoing another sowing will take place in the open in a fortnight's time. Although the dwarf kinds will continue to be grown, a climbing variety will be largely relied on for the summer and autumn supply. It would pay anyone having the convenience to do so to raise plants under glass either in pots or boxes and plant them out early in May.

Scarlet Runners.—By many these are preferred to French Beans, and when required as early as it is possible to supply them a sowing in slight heat should take place now, setting out the plants in shallow trenches containing a good depth of decayed manure about the second week in next month. Until the plants require staking, some pliable stakes bent over the row in the form of an arch will serve to carry protecting material when the state of the weather demands its employment.

Vegetable Marrows.—For planting in sheltered positions and on disused hotbeds where they will have the protection of fresh

lights for a time, the plants should now be raised. Seeds are best sown singly in 60-sized pots filled with ordinary potting soil, this saving all further trouble in the way of re-potting, as is the case when a number are raised in pans or large pots. Varieties are numerous, but those providing small or medium-sized fruits are most appreciated for the dining-room. Where quantity rather than quality is required, the varieties Long White and Long Green will yield excellent returns.

Potatoes.—Second early and maincrop varieties are being planted. Labour being scarce and planting very much in arrears, the sets are being dibbled in. The dibber has a blunt end and is shod with iron, there being a tread at one side to enable its being thrust into the soil expeditiously. Although this method of planting is not viewed with favour, there is, under the circumstances, no help for it, and one man can certainly plant a large breadth in a day. The holes are filled in afterwards by first breaking the soil down fine round them with a hoe. On heavier ground, which will shortly have to be planted a Canterbury hoe will be used for filling in.

Tomatoes.—The plants intended for planting outdoors have been moved into a frame, where they will be gradually inured to the outer air and hardened off.

Spring Cabbage.—The recent cold spell has retarded the turning in of such varieties as *Ellam's*, *Matchless*, *April*, and *Flower of Spring*. They have, therefore, been given a stimulant of 1 oz. of nitrate of soda to the square yard, which was at once hoed in. Harbinger is far and away the earliest variety, and although small, is of intrinsic value where a very early demand has to be met. A large breadth which will come in and succeed the former will have the soil between the rows dressed with sulphate of ammonia and then well hoed.

Zinnias.—For cutting in autumn as well as for the flower borders these are indispensable. The seed will now be sown in slight heat in boxes. As soon as the plants appear, they will be moved into a frame and grown on to the pricking-out stage as hardily as possible. Being quick-growing annuals, there is not the slightest need to accelerate growth, as they cannot safely be finally planted until the third week in May. A useful addition to the large-flowered varieties for cutting is *Z. Haagena*.

Wallflowers.—For spring bedding and cutting these cannot well be over-estimated, their fragrant flowers always meeting with just appreciation. A race of very early-flowering varieties is now to be had, among which *Yellow Phoenix* is a gem. Of those which come into flower the latter end of March and early in April, *Fire King*, *Cloth of Gold*, *Ellen Wilcott*, *Faerie Queen*, *Blood Red*, and *Purple Queen* are half-a-dozen sterling sorts growing to a height of 18 inches. Of the dwarf varieties, *Ruby Gem*, *Brown*, *Yellow*, and *Pink* are all worthy of cultivation, they being exceedingly useful for filling small beds. The double varieties, though later in flowering, are valuable for the flower garden and cutting. The seed is sown now in drills drawn 9 inches apart on ground which is capable of being reduced to a fine tilth. Pricking-out is done as soon as the plants are of sufficient size, in rows 1 foot asunder, 9 inches between plant and plant, and on soil of a holding nature to ensure their being lifted with good balls of soil in autumn.

Indian Azaleas.—As these pass out of bloom they are divested of the seed-vessels and stood together until the whole of the forwardmost have bloomed, when those that require it are repotted and others knocked out for drainage to be examined, rectified if out of order, and then top-dressed. They are then placed in heat and kept liberally syringed to induce them to break and make new growth. Such growths as are produced as a result of the plants being forced into bloom are sacrificed, these being too scanty to furnish sufficient bloom for another season. A good stimulant for Azaleas while making their growth is Standen's manure applied on the surface of the soil.

Azalea mollis.—These also pay if accommodation can be found to give them sufficient warmth to induce free growth after they cease flowering. If this is not possible they should be kept cool, when, if planted out in suitable soil they again become available for forcing in the course of a couple of seasons. They are also useful for planting in shrubberies where the soil is suitable for their needs.

Calanthes.—Of these *C. vestita* and its varieties, together with the hybrids *C. Veitchi* and *C. Bella*, are now starting into growth, and will be potted in a mixture consisting of fibrous loam, peat, with a little flaky leaf-mould, dried cow-dung, and a liberal quantity of coarse silver-sand. Clean pots, containing drainage to one-third of their depth, will be used. For the large pseudo-bulbs of *C. Veitchi* and *C. Bella* 8-inch pots will be used, three in a pot. For those of smaller dimensions, 6-inch and 7-inch pots will suffice. When potted they will be placed in a house where a temperature of 60 degs. to 65 degs. at night and 70 degs to 75 degs. by day is maintained.

Dahlias.—The tubers must now be taken from where they were stored in autumn last, and overhauled. As propagating of fresh

stock is for this season out of the question, the old tubers will be used for planting when the time comes round. A little attention in the way of reducing those which made a great number of tubers to due proportions will have to be given them, also in supplying new labels. They will then be placed in a cold-pit, covered with soil of a light description, and kept as cool as possible, removing the lights during the day, and covering with mats at night in addition to the lights if likely to be frosty. A. W.

MIDLAND COUNTIES.

Strawberries in pots.—Abundance of water and liquid-manure is afforded all plants which are fast swelling their fruit, and the syringe is used freely in bright weather till the berries begin to change colour, when both manure and syringing must be withheld. For syringing, the water should be very clean. As the fruits change colour air more freely and keep the house a little drier to assist the flavour, but do not lower the temperature too rapidly. A small batch of plants is now introduced about every ten days to keep up a supply.

Melons.—The fruits on the earliest plants are swelling fast, and need supporting. Square pieces of netting furnished with a length of string at each corner are the best for this. The plants are afforded a brisk top and bottom heat, abundant moisture, with liberal supplies of tepid water at the roots, supplemented with liquid manure. The foliage is copiously syringed twice daily, damping all dry surfaces and pathways frequently. A sowing is now made every three weeks, a few seeds only being sown at a time. Melons succeed very well through the summer in frames on hotbeds where a bottom-heat of about 75 degs. can be maintained. The present is a suitable time to sow seeds for raising a batch of plants for this purpose. Hero of Lockinge is a variety of good constitution and very suitable for frames.

Cyclamens.—Those forward enough will be potted into 5-inch pots. The pots must be clean and well drained, a suitable compost consisting of three parts good fibrous loam, one part leaf-soil, with a liberal addition of wood ashes and silver sand. I do not use manure in the soil, as I consider nourishment is best applied in liquid form when the plants have well filled their pots with roots. Place the plants in a warm, close frame near the glass on a bed of ashes, shading and syringing with soft water morning and afternoon until they are established. In about a week after potting gradually diminish the heat and give more air, carefully avoiding cold draughts. Extreme conditions of temperature are very injurious, and too much shade must not be given or the plants will suffer. Cyclamens, too, must never be allowed to suffer from want of water, as this will soon render them a prey to red-spider, thrips, and greenfly. Should these pests make their appearance dip the plants in a mixture of soft-soap and Tobacco-water.

Biennials and perennials of various kinds will now be sown on a well prepared border and pricked out as soon as large enough to handle.

Wallflowers.—Now is the best time to sow seeds of these. The seeds are often sown too late—in June and July—but the Wallflower requires a long season to develop into a sturdy, bushy plant that will stand the winter. Sometimes the plants are injured by sharp frosts following much wet in winter, this often resulting from sowing the seeds too late. Sow the seeds thinly in drills 6 inches apart, and as soon as the plants are large enough prick them out in an open situation in rows 1 foot apart and 9 inches between the plants. Pinch off the tap-roots as this induces them to form fibrous roots near the surface. If time and space can be afforded they will well repay transplanting a second time early in September, as extra sturdy plants will be produced with fibrous roots that can be lifted with the soil adhering to them for planting in their permanent quarters in November.

Half-hardy annuals.—Antirrhinums, sown in heat and pricked off into boxes have been well hardened off, and at the first favourable opportunity will be planted out in positions in which they are to flower. *East Lothian Stocks* and *Pentstemons* will also now be planted out in beds and borders. *Asters*, *Stocks*, *Nemesias*, *Phlox Drummondii*, *Salpiglossis*, and many other annuals sown in boxes have been pricked off into cold-frames.

Forsythias.—As these handsome flowering shrubs pass out of bloom they require, in whatever form they are grown, some annual pruning. The shoots made now and those that result from this pruning will furnish the flowering wood for another year. The flowering shoots of this year should be shortened back to three or four buds, and other pruning required may be done at the same time. *Forsythia suspensa* and *F. viridissima* thrive here planted in the open in sheltered positions. In very cold districts they require the shelter of a wall. As wall plants, the shoots should be nailed in loosely. If the soil around the bushes is found to be exhausted some of it should be replaced with turfy loam and rotten manure.

French Beans.—A sowing of these will be made the last week in April on a warm south

border, where protection can be afforded if necessary. The best way for early sowing of this important crop is to draw drills 4 inches deep and 18 inches apart, half filling the drills with old potting soil, afterwards planting the Beans and covering with the same soil. This method will ensure speedy germination and free growth, and will amply repay the cultivator for the extra labour of planting at this early date. Masterpiece, Sunrise, and Canadian Wonder are good varieties for sowing now.

Runner Beans.—It is yet too early to sow these in the open, but a crop may be had much more quickly by sowing in a cool-frame in pots or boxes, and then planting out in the open. Of course, large quantities are not needed, and a row or two of plants grown thus will suffice. If sown in heat the plants suffer if not thoroughly hardened off previous to planting out; but by sowing a little earlier in a cool-frame, and keeping the frame close until the seeds germinate, better plants are secured. If a sowing be made in the open about the second week in May this will form a succession.

Beetroot.—The main sowing may now be made wherever the weather is favourable on ground deeply worked and not manured, that occupied with Celery last year being very suitable. The larger-growing kinds will be better left another ten days or a fortnight, or the roots will in all probability be too large and coarse.

Celery trenches are being prepared for the earliest sowings. It is far better to put out the plants in a small state, provided they have been properly hardened, than to allow them to become starved. Solid Ivory is a capital variety for early use, as it matures quickly and takes up little room. The trenches should be taken out to a good depth and nearly filled with good manure. I consider it a mistake to plant too far away from the surface, especially on wet, heavy ground. It is only necessary to have the trenches deep enough to receive plenty of water. The ridges may be planted with Lettuces, where they will do well and will not be detrimental to the Celery crop.

Vegetable Marrow seeds should be sown singly in 4-inch pots and placed in a close frame for planting out at the end of May. Where early supplies are desired a few seeds may be sown in a frame, where the plants can be allowed to grow until they have reached the height of the pit, when, if all danger of frost is past, the sashes may be removed, and the plants allowed to run. In this way Marrows may be cut greatly in advance of those grown in the ordinary way.

Cucumbers.—If seed be sown now the plants will be ready for planting in about a month, a time when frames on hotbeds that have been used for propagating bedding plants and growing early vegetables are no longer required. Such frames may be advantageously used for growing Cucumbers during the summer. The heat from the hotbeds, if properly made at the start, will be sufficient for the Cucumbers. Plants in bearing require to be frequently looked over for the purpose of tying in, and stopping sufficient young shoots at the second joint to cover the trellis without crowding, taking out the surplus old leaves and growth that has borne fruit. Add a top-dressing of soil when the previous one gets full of roots, which takes but a short time.

Tomatoes.—The earliest batch of plants has set a good crop of fruit, and is afforded weak liquid-manure at every other watering, and occasional slight doses of Le Fruitier. Plants for succession have been placed in their fruiting pots. Those intended for fruiting in the open are ready for shifting into 5½-inch pots, and are induced to make good, strong, sturdy plants. Small, late plants cannot be depended upon, and are practically worthless.

Potatoes.—Planting should be completed as soon as possible. F. W. GALLOP.

SCOTLAND.

Stove.—Fine-foliaged plants are now growing freely, and to maintain them in good health the free use of the syringe is needful. The water must be pure and free from sediment. Rain-water is undoubtedly the best for syringing. Shading will soon be necessary, but where many *Dracenas* and *Crotons* are grown it may be advisable to leave a portion of the house unshaded, these plants revelling in bright sunshine. Plants for draping stages are always useful, and pots or (preferably) pans of *Selaginellas* ought to be provided. Certain of the *Tradescantias* are useful for this purpose, as also is the Indian Grass (*Panicum variegatum*). Another less-known subject is *Ceropegia Woodii*, with slender stems and fleshy leaves, and which can be readily propagated from cuttings in bottom-heat. Night temperature from 65 degs. to 68 degs., according to outside conditions. Fire-heat need not now be excessive if early closing is resorted to, and with fuel not only scarce but rising in price, sun-heat ought to be utilised as far as possible.

Caladiums.—These should be potted without delay into the pots which they are to occupy throughout the season. There are some very fine named varieties now procurable; but for general purposes it is not necessary to go to

the expense of such sorts, an ordinary mixed lot being quite useful. The pretty silver-leaved variety *C. argyrites*, still holds its own among the dwarf kinds, and is useful for table work in small vases. All *Caladiums* require plenty of moisture throughout their period of growth. I have seen them very effectively grown planted out under the stages of a warm house, the foliage of such plants being useful for cutting. In

Vinerias a little air must be given along the ridge quite early in the morning when the sun is bright. This checks the condensation of moisture on the berries and prevents to some extent any disposition to rust. Keep ventilation well abreast of the rising thermometer; but delay using the side ventilators as long as possible at this comparatively early period. Cold draughts are easily admitted from the bottom, and are apt to induce mildew. Artificial manure can now be safely given, and it is just as well to give a change of stimulant from time to time. There is plenty of good Vine manures on the market, and the roots relish a change now and then. Sublateral growth must be kept down by regular attention at the necessary intervals, and the night temperature should be kept round about 63 degs. to 65 degs.

Late Peaches under glass.—As soon as the embryo fruits are visibly set, thinning and disbudding may be profitably commenced. Do not hurry to complete the work, but spread it over a fortnight or even three weeks. If many superfluous fruits are set remove those situated under the branches, and endeavour to fix the fruits on the upper sides, where they will receive all the sunshine possible and be highly coloured when ripe. In disbudding, the shoots, both from the upper and under sides of the branches, should be gradually removed. Sufficient shoots for furnishing may be secured from the sides, and, after all, only a few of these are necessary. Some judgment, of course, is necessary; and in young trees more wood is left than is needful in the case of established trees, but it is safe to say that one of the chief causes of failure with Peaches and Nectarines is the practice of leaving too much rough wood in young trees. Some attention paid to the constitutions and requirements of the different varieties goes a long way in deciding just how much wood it is desirable to retain.

Hardy fruit.—Owing to a spell of fine weather it has been needful to water the majority of the trees of stone fruit upon the walls. When this course is followed it is done in no half-hearted way, every tree receiving a thorough root-watering. After this those trees which were mulched have the coverings rearranged, this conserving the moisture. Peaches and Nectarines are being hand-fertilised daily. Up till now no frost of any severity has been experienced, and so the trees have not been covered for the present season. As previously indicated, I consider it to be the better practice to keep the trees uncovered whenever possible, but, naturally, the coverings are ready to hand, and can be put on at once.

Raspberry canes.—These are breaking freely, and in the course of the week the ground, after having had a good dusting of chemical manure, was well hoed up. The recent mild weather has resulted in growth being much further advanced than is generally the case at this date.

Hardy-flower borders.—Aided by the fine weather much further progress has been made among the hardy-plant borders in the way of staking, etc. It is always a tedious business to get over these borders for the first time. On several of the smaller borders, after having been cleaned, seeds of hardy annuals were sown broadcast, a distinct variety being used for each. Thus, one was sown with *Saponaria calabrica*, another with *Nemophila insignis*, a third with *Godetia Lady Albemarle* (dwarf), a fourth with *G. Duchess of Albany* (dwarf), and so on. These borders are always very interesting treated in this way, and the seedlings, being early and rigorously thinned, the display endures over a long time. When they begin to grow shabby they are cleared away, and this is generally done just before the late autumn display of the hardy plants reaches its best.

Gladioli.—These ought to be planted now. There are many ways of planting them, all equally good—in lines, in groups, or in beds. Grouping is, perhaps, the most popular way, half-a-dozen or so in a group. Personally, I think planting in heds is the most effective way. One large bed here last year was very fine, and the spikes of the Gladioli rose through a carpet of *Aloysia citrodora* and Sweet-scented Pelargonium in mixture. This season the ground will be carpeted with *Nemophila insignis* or a dwarf blue Lupin. Successional plantings will be made for some time, chiefly in groups, for the purpose of securing late spikes.

Mignonette.—Successional sowings must not be omitted. In some gardens Mignonette fails, but if the bed be raked to a fine tilth and after the seeds are sown firmly beaten with the back of a spade, success is fairly certain. Seed-eating birds are sometimes responsible for the failure of Mignonette, and to prevent them from doing damage damp the seeds and coat them thoroughly with red lead.

Late Potatoes.—During the week preparations have been made in view of the forthcoming planting of late Potatoes. A considerable area is devoted to this crop, and, although the ground has usually been cultivated by the spade, during this season it has been ploughed. The soil, now in excellent order, has been well harrowed and all weeds and stones removed. Shortly the Potatoes will be planted by dibbling the seed tubers in lines on the flat instead of in drills. By this means the quarter will be more easily kept clean until it is time to fork up between the lines, after which moulding up will be done by the plough.

Peas and Broad Beans were again sown. Of the former, the varieties sown at this time were Duke of Albany and Alderman, two Peas which, if sown upon the same date, form a very useful succession. Harlington Broad Windsor Bean is preferred for present sowing.

Digging vacant quarters.—As soon as ground is cleared of exhausted winter vegetables no time is now permitted to elapse until it is manured and turned up. The soil at this time of the year is not thrown up roughly, but is broken rather finely as the work goes on. This saves time in forking at a later date, a run over with wooden rakes being sufficient when the quarter is again required.

W. McGUIROG.

Balmoe Gardens, Kirkcudbright.

NATIONAL ROSE SOCIETY.

APRIL 14TH, 1916.

THE spring exhibition of this Society was held at the Royal Horticultural Hall on the above-named date. It compared favourably with that of last year from the competitive point of view, the quality of the blooms showing a distinct advance. Varieties of outstanding merit throughout the show were Sunburst, Mrs. George Norwood, and Mrs. Foley Hobbs, thus demonstrating a special fitness for early work. In addition, the silver-medal blooms—Mrs. Edward Mawley and William Shean—attracted everybody. The magnificent dozen of *Maréchal Niel* from Mr. Goodwin, Maidstone, were in the nature of a revelation, hardly less so a vase of Sunburst from Mrs. Courtney Page. For colour, Mme. Collette Martinet (rich orange apricot) was alone. The "Gold-medal" Rose of the occasion was Mrs. Bryce Allen, H.T., a shapely, delightfully-fragrant variety of rosy-red colour. Following are the more important exhibits.

NURSERYMEN.—SECTION I.

Two entered for the group of Roses in pots, the leading award going to

Messrs. Hobbies, Ltd., Dereham. Pillar, Polyantha, and weeping *Wichuraiana* varieties occupied the central parts. Around and in the ground work were such as Sunburst, Dean Hole, Ophelia, and Melody, Baby Elegance occupying the margin with Ferns. Messrs. Paul and Son, Old Nurseries, Cheshunt, were second with a less well-garnished group, yet showing very fine blooms. Sunburst, Edward Mawley, the fine white Mrs. H. Stevens, Mrs. A. R. Waddell (apricot), Lady Hillingdon, and Mme. Edmee Metz (pink) were some of the best. For a group of pot and cut Roses in a space of 100 square feet,

Mr. G. Prince, Longworth, took the leading prize, arranging pillars of such as Hiawatha, Excelsa, White Dorothy, and the new pink Rambler, Chatillon, as a background in conjunction with stands and vase groups of Lady Hillingdon, Old Gold, Melody, Austrian Copper, Mme. E. Herriot, and many others. Mr. Elisha Hicks, who was second, had excellent standards of his new pink-flowered Mrs. George Norwood, which, it is claimed, is the most fragrant Rose ever raised. Dean Hole, Mme. Second Weber, and Mrs. Charles Reed were others of note.

Messrs. B. R. Cant and Sons, Colchester, staged in the cut and pot-group class Silver Moon, a magnificent single white, believed to be a seedling from *Sinica Anemone*, surpassing all else, Hon. Mrs.'

R. C. Grosvenor (gold and blush), George Dickson (intensely rich and dark), and Lyon Rose being other good sorts.

Messrs. Paul and Son, Cheshunt, were first for six pillar Roses in pots, showing Coronation (red), White Dorothy, Excelsa, Hiawatha, and others.

Messrs. Paul and Son led for six weeping standards, distinct, having, among others, American Pillar, Lady Gay, Sodenia, and the rosy-flowered Mme. Casimir-Mouille. Mr. George Prince was second.

Mr. Elisha J. Hicks, Twyford, was first for six pots of new Roses, not less than two varieties, showing standards of his new pink, Mrs. George Norwood, Mrs. Andrew Carnegie (white), Mrs. Charles Reed (a lovely pink and blush-white), and Edith Part, among others. In this class the standards not only afforded diversity but demonstrated the fitness of the varieties named for this particular mode of cultivation. For fifty Polyantha Roses in pots, not larger than 6 inches in diameter, Mr. Hicks was first.

CUT BLOOMS IN BOXES (NURSERYMEN).

Messrs. B. R. Cant and Sons, Colchester, secured the first prize for thirty-six blooms, not less than twenty-four varieties. One of the finest Roses in the show, Mrs. Edward Mawley (silver medal), was in this set. Edward Mawley (red), Dean Hole, Yvonne Vacherot, and Antoine Rivoire were other good things. Messrs. F. Cant and Co., Colchester, were second, showing excellent blooms of Mrs. Edward Mawley, Mrs. Foley Hobbs, Mildred Grant, Cleopatra, and others.

Mr. Elisha Hicks was first for eighteen blooms, not less than twelve varieties, with a capital lot, Mrs. George Shawyer, Mrs. Foley Hobbs, Dr. J. C. Hall (rose), Mme. Jean Dupuy, and Maman Cochet being very fine. Messrs. G. and W. Burch, Peterborough, had excellent examples of Mrs. Foley Hobbs and William Shean, among others, and took second prize.

Mr. A. T. Goodwin, Roseholm, Maidstone, took first prize for the third time in succession for twelve blooms of *Maréchal Niel*. The blooms were remarkable for colour, size, and substance, and we doubt if finer have ever been staged.

Messrs. Burch were first for twelve blooms of any other variety with Frau Karl Druschki.

Messrs. F. Cant and Co. were first for six distinct, not more than five stems of each, their best being Lady Ursula (pink), Capt. Hayward (scarlet), and Frau Karl Druschki. Mr. Elisha Hicks was second, staging Mme. C. Lutania (golden apricot), British Queen (white), and Mme. Second Weber.

AMATEURS.

Mr. E. J. Holland, Sutton, Surrey, and Mr. G. A. Hammond, Burgess Hill, were awarded equal first for twelve cut blooms not fewer than six varieties. We were unable to agree with the judges' decision in this case. The latter exhibitor's Roses were, we thought, much superior, albeit lacking in coloured varieties. Mr. Holland's collection contained William Shean (silver medal), a large, yet less beautiful and refined bloom than Mr. Hammond's bloom of Mrs. Foley Hobbs. Both blooms of Dean Hole in Mr. Holland's set were, we thought, weak; certainly small and of poor colour. In the ladies' vase class,

Mrs. Courtney Page, Enfield, showed Sunburst magnificently. Of this variety the show contained nothing finer: clean, refined, beautiful, and as near perfection as could be desired.

TABLE CLASSES.

Mrs. Oakley Fisher was awarded first for a setting of Lady Hillingdon, Acer foliage and other things in brown wicker baskets; second, Mrs. F. A. Tisdall, whose Sunburst, with Asparagus, was particularly good. We strongly favoured the arrangement of Mrs. Courtney Page, who was placed third with a superb lot of Ophelia, a lovely pink and cream in perfect condition, the first-prize table in the opinion of many. It would be interesting to know on what lines the tables were judged. In the nurserymen's section Mrs. A. R. Bide, Farnham, was alone, employing the unique Mme. Collette Martinet (rich orange apricot), and taking first prize.

The list of certificated plants and medals at the Royal Horticultural Society's meeting on April 18th, as also the awards of the Narcissus Committee, will be found in our advertisement columns. A report of the latter will appear next week.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Freesias the second year (H. F. W.).—To grow Freesia bulbs so that they may be depended on to flower the second year they need a good place in the greenhouse after they go out of bloom, proper attention to watering, with a little liquid manure occasionally, and as they show signs of going to rest exposure to full sun in order to ripen them. This will be about midsummer or a little later. When the leaves have all dried off stand them on a sunny shelf and give no water. In August turn out of the pots, shake clear of soil, size the bulbs, and repot. We much prefer, however, to purchase fresh bulbs every year, as the difference in blooming between home-grown bulbs and those imported is very considerable.

Zonal Pelargoniums for winter (M. T.).—To have Zonal Pelargoniums in flower during the winter months cuttings should be taken at once. Insert singly in small 60 pots in equal proportions of sandy loam and leaf-soil, and stand in a warm greenhouse. When the cuttings are well rooted and commence to show a little growth, pot on into 5-inch pots, and stand in a cool frame for their summer quarters. Keep all long shoots pinched back to form a plant of good habit, and pinch the flower-buds out as they appear. At the end of July another shift may be afforded, a 6-inch or 7-inch pot being a useful size. Place back into the frame, and continue pinching for a month or six weeks. For the final potting loam and leaf-soil in equal proportions, with the addition of a little well-rotted stable-manure, are essential, and a small portion of sharp sand. At the beginning of September discontinue pinching, and allow a little stimulant twice a week. We recommend cow-manure. As soon as the plants begin to show flower, stand in a greenhouse for their winter quarters. Care should be taken during the winter months with the watering.

FRUIT.

Disbudding Vines (Inquirer).—This consists in removing the young shoots which are not required, and the sooner this is done after the bunches of Grapes can be seen the better. All healthy, vigorous Vines will throw out more shoots than there is room to lay in. As a rule, one shoot to each spur is quite enough to leave. Go over the Vines as soon as they break and take off all weakly buds; but, in doubtful cases, where one cannot identify the shoot which is destined to carry the best bunch, two of the most likely ones are left, and a final selection made later on when the bunches are more developed.

Repotting an Orange (A. G.).—This is the best time of year to repot your Orange-tree, but do not place in cold draughts after repotting. If you can give the plant stove treatment for six weeks or two months it will do well. Syringe daily, keep foliage free of insects, and do not overwater at the root. If you can give the roots a little bottom-heat after repotting for a few weeks it promotes a good start. If unable to, frequently damp overhead, but not so heavily as to saturate the soil. Use good turfy loam, some pieces of broken charcoal, and dried cow or spent Mushroom manure. Pot firmly, with plenty of drainage.

VEGETABLES.

Tomatoes in unheated greenhouse (Grower).—Tomatoes may be grown either in pots or boxes, but in your case we should prefer a trough made with one board on the bottom, unless the border could form the bottom, and an 11-inch board to form the front, the back of the bed resting against the

wall. The trough thus formed may be 15 inches or so wide, and should be filled with a mixture of two parts loam, one part stable-manure, not too damp or rich, and some old mortar or plaster, or crushed charcoal, or a little charred material. Set the plants out 18 inches apart. Do not use stimulants till the first trusses are set and the fruit swelling; then any kind of liquid-manure will be useful.

MISCELLANEOUS.

Shading for a conservatory (J. C.).—Do not paint the glass over with permanent shading material, it is a very bad plan. In a general sense nothing is better for the purpose than thin scrim canvas outside blinds, made to roll up or down. Any intelligent local carpenter will make the roller and fix the blinds. If these can be arranged so that they will roll up under a protecting board, so much the better.

Grass mowings (A. B. Wilson).—If the summer is dry it is a good plan to remove the Grass box of the mowing-machine—*i.e.*, if you mow the Grass every week—and leave the mowings on the lawn. They prevent the Grass being burnt. If you do not care for this, then you may collect the mown Grass and use it as a mulch for the various crops in the kitchen garden or spread it over the flower beds. This mulch will help to retain the moisture and save watering.

SHORT REPLIES.

R. P.—Kindly send some specimens of the caterpillar you refer to, and then we can better help you.—*Holmestrove.*—The most probable cause is that the shoots, being very green and sappy, succumbed to the very severe weather we had during March.

Tropaeolum Dr. Mules.—Can any of your readers inform me through GARDENING ILLUSTRATED where I can procure plants of Dr. Mules' climbing scarlet Tropaeolum? It is a most distinct and beautiful Tropaeolum. Until the last two years I have been able to buy plants, but since then I cannot find anyone able to supply me. I have tried many nurserymen, but the plants I have received have proved similar, but not the correct kind. Many gardeners in this district would be very pleased to get the right kind. Dr. Mules, who brought this Tropaeolum out, was an eye-specialist in Bowden, near Manchester.—*HOLLIES.*

OBITUARY.

MONS. F. JAMIN.

I REGRET to announce the death of a much respected French nurseryman, Mons. F. Jamin, of Bourg-la-Reine. He was, among other things, Vice-President of the National Society of Horticulture of France, and a grower of fruits and plants generally. As a young man he had been to England—I think, in Messrs. Rivers' Nursery—and he was always very glad to meet English people. I got some of my best fruit-trees from him, and my Clematises on their own roots. Pyramids of Perle d'Azur, from layers, every year remind me of him with their thousands of blooms. I sincerely hope that he will have some worthy successor. He always had a good stock of Clematises on their own roots, layered in little pots, so that they could be easily sent out all through the planting season. Like others, he had followed the grafting delusion for some time, and regretted to me that he had ever given up his layering ground, which is the right way of propagating many shrubs and climbers. He had also a very beautiful jardin fruitier.

NOTES OF THE WEEK.

Dittany of Crete (*Origanum Dictamnus*).—Looking over Tournefort's "Travels in the Levant," I see the figure of a plant like this in the book, and very well figured. I regret I fail in growing this curious plant. I think its best place would be a dry wall or some specially warm soil.—W.

The great Pilewort (*Ranunculus ficaria-formis* F. Schultz) (*Ficaria grandiflora* Robert).—This, referred to lately, is rightly named. As regards its being distinct from the little Celandine there can be no doubt of its being so as a garden plant. The main thing for us is that it is a first-rate plant for spring garden use.

Narcissus cyclamineus at Edinburgh.—In the first week of April a delightful little group of the charming *Narcissus cyclamineus* was in bloom in the rock garden of the Royal Botanic Gardens, Edinburgh. This Daffodil is not plentiful in the north, and one may go through many gardens before meeting with it. In Edinburgh it seems to do particularly well.

Anemone stellata.—There is at present (April 21) an excellent display of this Windflower. The colours vary from rosy-white to a purplish-crimson, the blooms of the latter being larger than those of the former. All these—over a thousand in number—were imported from Italy, and, so far, are turning out well, although a very severe winter might possibly try them.—W. McG., *Kirkcudbright*.

Primula Winterei in the open in Edinburgh.—Quite a pleasant picture was made in the rock garden of the Royal Botanic Gardens, Edinburgh, by a group of *Primula Winterei*, which was coming into bloom the first week of April. Some flowers were already expanded, and the group, nestling at the base of the large rocks and sheltered from the wet and winds by some which overhung, looked remarkably well. *P. Winterei* is quite hardy in these gardens.

Gigantic Arums.—A recent note, over the signature of "An Old Friend," is interesting in so far as it shows the enormous height of flower-stem and size of spathe. Otherwise, as in the case of many other things, size is really a drawback, medium-sized flowers being preferable for ordinary work. If a florist were asked which he would prefer, large or medium-

sized spathes of Arum Lilies, he would at once answer in favour of the latter, for the reason that it is difficult to work other flowers into the interstices left by exceptionally large spathes. In private places, too, medium-sized blooms, having thinner stems, can be more easily used in vases, especially long and slender glasses.—KIRK.

The white Snow Glory.—This graceful flower is now in bloom, and well worth growing. It seems stronger than *Chionodoxa Luciliae*. We have to thank Mr. Maw for it, and I am looking forward to some charming associations of this with the blue form, both hardy bulbs that in some free soils might be naturalised.—W.

Pontic Kingcup (*Caltha polypetala*) as a cut flower.—This is the handsomest hardy plant that has been introduced for a dozen years. It is very good for the house, and lasts well there, looking very pretty in a little bed of Wood Forget-me-nots. It is good in all situations, such as in ponds, fountain basins, and even a moist border.

Tufted Pansy Marguerite.—Although it is now nearly twenty years since this variety was introduced it is still favoured by many. Its habit is neat and compact, while its freely-produced flowers are of a pale primrose-yellow, rayless, and with a deep yellow eye. Individual blooms possess much substance, and have exceptionally long foot-stalks, so that they have a certain value for cutting. The variety is very useful for massing, and, if the spent flowers are regularly picked, it continues to bloom freely till late in the season.—KIRK.

Primula Juliae.—This has stood the winter, and is giving a plentiful supply of bright purple flowers just above its close-growing mat of foliage. It is a very dwarf plant, being barely an inch or two in height. It is a gem for the border, the bog garden, the stream-side, or the moraine. In the last-named it has flowered earlier with me than anywhere else. It is a Caucasian species, discovered in 1901, and first recorded in bloom in this country in the Oxford Botanic Gardens in 1910. It increases freely, but there are two forms, one flowering much more freely than the other.—S. ARNOTT, *Dumfries*.

The Spring Star Flower (*Brodiaea uniflora*).—I grow this as a wide edging in front of Azaleas, where the soil is cool but not good, yet well exposed to sunshine. The bulbs have occupied this position for some years. As I write (April 15th) the

plants are almost hidden by myriads of pale blue star-shaped flowers, a violet stripe running down the centre of each petal. The effect is beautiful, especially in the middle of the day, when the fragrant flowers are fully expanded. The flowers, borne on stiff stalks each a foot in length, last well when cut. Individual flowers appear all the winter through, but it is at the present time such a glorious profusion of bloom is produced.—E. M.

Ranunculus cortusae-folius.—This handsome plant, too tender for the open air in most of our British gardens, is excellent for a cool-house, especially where it can be planted out. It was finely in flower in the early days of April in one of the houses of the Royal Botanic Gardens, Edinburgh. It is planted out, and had there exceeded considerably its book stature of 2 feet. The very large flowers, of a glistening yellow, were very fine. Although introduced so long ago as 1825, *R. cortusae-folius* is but little seen. It well deserves a place in the alpine houses which are becoming so popular. Although not an alpine in the proper sense of the word, it might be associated with the smaller hardy flowers with advantage.—S. ARNOTT.

An early Cherry (*Prunus subhirtella*).—The flowers of this Cherry are at their best in early April, in advance of those of the large-flowered *P. serrulata* and the varieties of the European Cherries. A native of Japan, it was introduced to the British Isles in 1895. At its best it is only a small tree. In Japan its height is said to be from 20 feet to 30 feet, and here it will probably reach maturity at from 15 feet to 20 feet high. The head is wide, spreading, and made up of numerous slender branchlets, from the axillary buds of which clusters of pale rose-coloured flowers are borne from early April onwards for two or three weeks. Its early flowering appears to be against the production of fruit in this country, for so far none has been recorded. That, however, is of little moment, for cuttings of half-ripe shoots root quite readily if inserted in sandy soil in a close frame during the early part of July. Plant if possible so that the tree will have a background of dark foliage, for the flowers are seen to greater advantage under such circumstances than against an unbroken sky-line. It is also desirable to protect against north and east winds, for cold winds seriously injure the delicate blossoms. A closely allied *Prunus* is the Rosebud Cherry of

Japan (*P. pendula*), the principal difference being in the pendent branches of the latter. It is, however, a less desirable tree for general planting, as it is rather easily injured by late frosts.—D.

Primula vincæflora.—This charming Primula, which Professor Bayley Balfour, in his paper at the Primula Conference in 1913, stated had been grown in the Edinburgh Botanic Gardens for five years without flowering, was in bloom in the beginning of April. The leaves are surmounted by a lengthy stem, bearing a large flower of Violet-like shape, and of a most beautiful blue-purple. In form the flowers are quite unlike those of the greater number of the Primula species. It remains to be seen how far *P. vincæflora*, with its distinct flowers, will lend itself to cultivation in our gardens, either in the open or under glass. Probably the latter will be the more suitable.—S. ARNOTT.

Rhododendron Pink Pearl.—The parentage of this fine hybrid is said by "D." (page 193) not to be generally known. Some years ago I communicated to the *Field* newspaper information which I received in Edinburgh to the following effect: When the stock of Peter Lawson and Son, of Edinburgh, was sold by auction, Messrs. Methven bought a large number of seedling hybrid Rhododendrons. Some years later, when Messrs. John Waterer's traveller was inspecting Messrs. Methven's stock, one of these hybrids was flowering, which he purchased, and this, I was told, was the original Pink Pearl. Messrs. John Waterer wrote to the *Field* to say that I had been misinformed, and that Pink Pearl was a hybrid raised by themselves, but they declined to state its parentage. It is neither my interest nor my desire to express an opinion as to which of these two conflicting accounts is correct, each coming from a source of undoubted integrity. I think it is obvious that *R. Griffithianum* is one of the parents of Pink Pearl, and it is well known that Mr. Peter Lawson, a noted enthusiast in this genus, used that species largely in the production of hybrids; but Messrs. John Waterer may have done so also. Their motive in keeping secret the parentage of Pink Pearl is not clear.—HERBERT MAXWELL, *Monreith*.

The Pasque Flower (*Anemone Pulsatilla*).—Large numbers of this beautiful Windflower are now in bloom, some of the plants, which have been established in their present position for several years, carrying from fifty to eighty flowers. Like many other valuable spring flowers, it has in many instances been cast aside, which is unfortunate, as it robs gardens of one of the choicest of hardy plants. The large, drooping buds appear from among a fringe of silky grey hairs, and these are seen to much advantage in the early morning when covered with dew. Although the general tone of colour in the flowers is mauve there are violet, red, and white kinds equally attractive. This plant is fond of limestone soil, but this is not absolutely necessary for its successful culture, as the soil here is devoid of lime. The plants referred to are used as an edging along the side of old flagstones set up edgewise in place of tiles, and to which they seem to cling. The soil is of a sandy clay nature, known among gardeners as soapy. In this the plants are quite at home, and annually provide a feast of their beautiful flowers on stout stems a foot in length. The flowers are splendid for cutting, and last well indoors. During the past winter a group has been planted in a little shade, and this when established should prolong the season of bloom.—E. M.

VEGETABLES.

THE MANURING OF COTTAGE GARDENS AND ALLOTMENTS.

OF the chief food ingredients required by plants only three, viz., nitrogen, phosphates, and potash, have to be applied directly in the form of manure. Farmyard manure contains all three, but artificial fertilisers usually contain only one or two of the necessary ingredients.

A fourth substance, lime, is required, not so much as a plant food as on account of its action on the soil.

FARMYARD MANURE.—The manure at the disposal of the cottager and allotment holder is often poor in quality as compared with farmyard manure made in well-constructed cattle-feeding yards. It is apt to contain too much straw, or other litter, and too little of the animal excreta. In view of the bulk of material applied, therefore, the crop returns obtained from its application are often disappointing. When the manure has to lie for some time in a heap before application it should be covered with about 6 inches of soil in order to preserve the fertilising material. In the case of heavy soils the manure is best dug in during autumn and winter; in the case of light soils this should be done in spring, some time before cropping. The undecayed portions of the manure should preferably be used for the green crops (Cabbage family), the more completely decayed portions for the root, fruit, and flower crops. An average market-garden dressing of manure would be about 2½ cwt. to 3 cwt. per rod (30¼ square yards). A large barrow-load of moderately decayed manure will usually weigh about 1 cwt. Where the full dressing of ordinary manure cannot be obtained artificial manures, as indicated below, may be applied with advantage.

POTATOES.—Where the crop is grown on the flat, sulphate of ammonia should be applied on the surface just before the first earthing up, at the rate of ½ oz. per square yard (1 lb. per rod, or 1½ cwt. per acre). Where Potatoes are planted in drills the sulphate of ammonia may be applied in the drills at the time of planting. Superphosphate of lime should be applied at the rate of 1½ oz. per square yard (3 lb. per rod, or 4¼ cwt. per acre), and may be forked in lightly before planting on the flat, or applied in the drill at the time of planting; or superphosphate and steamed bone-flour may be mixed in equal proportions and applied when planting at the same rate as in the case of superphosphate alone.

CABBAGE FAMILY.—All the members of this group respond to applications of nitrogenous manures. Sulphate of ammonia should be applied at the rate of ½ oz. to ¾ oz. per square yard (1 lb. to 1½ lb. per rod, or 1½ cwt. to 2 cwt. per acre) before the first earthing up, or as soon as growth starts. Where Cabbage crops are slow in "hearting," and Turnip crops refuse to "bulb," phosphates are usually deficient. Superphosphate should be applied, alone or in combination with steamed bone-flour, at the rate of 1 oz. per square yard (2 lb. per rod, or 3 cwt. per acre) at the time of planting, or before the first earthing up.

In inland districts, where allotment crops on light and medium soils are liable to suffer from drought, salt is very helpful and will usually increase the crop. It should be applied at the rate of 1 oz. per square yard.

PEA AND BEAN FAMILY.—Crops belonging to the Pea and Bean family can usually provide themselves with sufficient nitrogen. A mixture of superphosphate

and steamed bone-flour, in equal proportions, should be applied to the ground, before or after sowing the seed, at the rate of 1 oz. to 4 yards in length of drill. The mixture should never be sown in the bottom of the drill so as to come into direct contact with the seed.

ONIONS, LEEKS, AND CELERY.—Sulphate of ammonia should be applied at the rate of ½ oz. per square yard (1 lb. per rod, or 1½ cwt. per acre), with superphosphate and steamed bone-flour, mixed in equal proportions, at the rate of 1 oz. per square yard. On light soils, liable to dry out, salt may be given with advantage (1 oz. per square yard). These crops should all be manured in the early stages of growth.

CARROTS, PARSNIPS, AND BEET.—Sulphate of ammonia should be applied at the rate of ½ oz. per square yard after singling. Superphosphate and steamed bone-flour, mixed, at the rate of 1 oz. per square yard, should be applied before sowing the seed. On dry soils 1 oz. of salt per square yard may be applied before drilling.

LETTUCE, SPINACH, AND RADISHES.—These are greatly helped by applications of sulphate of ammonia, which should be applied at the rate of ½ oz. per square yard in the early stages of growth. Where Radishes do not "bulb" readily superphosphate, at the rate of 1 oz. per square yard, should be applied to the soil before sowing. Where the soil is known to be over-stocked with organic matter (containing nitrogen), producing a very rank growth of leaf, the sulphate of ammonia should be withheld. This reservation applies to all the crops dealt with in this article.

LIQUID MANURE FOR FRUIT AND FLOWER CROPS.—One peck of poultry manure or one peck of sheep droppings placed in a 40-gallon cask and filled up with water will, after standing twenty-four hours, make an excellent liquid manure if applied while fruit is swelling, and in the case of flowers while the blooms are opening; 2 gallons per square yard should be applied weekly. Where the above materials cannot be obtained, ¾ lb. sulphate of ammonia and 1 lb. superphosphate in 30 gallons of water will make a safe liquid manure, which may be applied at the rate of 2 gallons per square yard.

GENERAL CONSIDERATIONS.—The recommendations made above are drawn up to meet the conditions now existing with regard to the supply of chemical manures. Potash salts are hardly obtainable, but wood ashes, which contain potash, should be collected and applied at the rate of 1 oz. per square yard to soil in which Potatoes, Peas, Beans, Carrots, Parsnips, and Onions are to be grown. The richest ash is produced by hedge clippings, prunings of fruit bushes, Nettles, and coarse-growing weeds burnt before they are fully ripened. The ash of timber may contain little potash. Ash must be collected as soon as possible after burning, as rain quickly washes out the potash. Recent experiments tend to show that members of the Cabbage family can avail themselves of the stores of potash already in the soil to a greater extent than most other crops, and this circumstance should be borne in mind while potash is scarce. On heavy soils, and soils rich in organic matter, basic slag may replace superphosphate, particularly in districts with a good rainfall. The quantity used should be from one and a half times to twice as much as is recommended in the case of superphosphate.

The present prices of the manures referred to in this article are about as fol-

lows, when bought in quantities of 1 ton or more :—

		Per ton
		£ s. d.
Sulphate of ammonia	20% of nitrogen	17 0 0
Superphosphate	35% of soluble phosphates	5 0 0
Steamed bone-flour	1% nitrogen and 60% insoluble phosphate	7 0 0
Basic slag	20-30% of total phosphates	1 14 0
Agricultural salt		2 10 0
		1 12 0

Allotment holders should order their manures co-operatively so as to save on the carriage and secure the advantage of the lower prices at which dealers are prepared to quote for considerable quantities.

The prices charged for small quantities of 1 cwt. or less vary very much with the district and the cost of carriage from the nearest manure works.—*Journal of the Board of Agriculture and Fisheries.*

Mushrooms.—Beds which have been bearing throughout the winter have been given water at a temperature of 85 degs. This has had the desired effect. Applying water for this purpose requires to be done

PLANTS AND FLOWERS.

INDOOR PLANTS.

NOTES AND REPLIES.

Acacia dealbata failing.—There is an Acacia dealbata in the conservatory of these gardens that is almost a failure. It is planted out in loam, peat, and sand, about 2 feet in depth, aspect south-west. It is about six years old, but made rapid growth the first year after planting. I stopped it in the spring of last year when about 10 feet high, since then it has made very little wood or side growths, and the leaves fall off. There is a small ventilator on the roof, which opens direct on the head of the plant, and, thinking that was the cause of failure, I left off using it. The temperature is kept about 55 degs.—HENRY PENFOLD, *Down's Court, Sandwich.*

[Acacia dealbata is such a vigorous grower that we cannot understand your specimen behaving as it has done. Is the border drained so that the surplus water can run away? If not, the roots may be in a poor state. Should conditions be

and sand would have been better. When potting, you would, of course, have an opportunity of observing the condition of the roots. If they are unhealthy it may have been caused by an excess of moisture, or the reverse, for large plants may often appear moist on the surface and yet be very dry in the interior of the ball of earth. In a general way, however, too much moisture is at the root of the trouble. It is also quite possible that the plant has been kept too warm and shaded at some time, and this would cause the leaves to die off.]

ROSES.

ROSES ON ARCHES AT PECKHAM RYE PARK.

Roses are seen to the best advantage when growing over arches and arbours. Fortunately, there are a wide selection, and many forms and colours, so that we can

An arch of Roses in Peckham Rye Park.

with judgment, as it is the soil casing alone of the beds which needs moistening. If the manure beneath it becomes saturated the mycelium perishes and a further supply of Mushrooms may be looked for in vain. As the house invariably becomes too hot from now till autumn comes round for Mushrooms to be grown successfully, a cooler place has to be found in which to grow them during that period. Sheds or disused stables answer well for this purpose, and later on beds can be made up in the open if necessary. In these several instances the beds should be made upon the ground surface in the form of a ridge, 3 feet in width and 2 feet in height. To eke out the supply of manure or droppings four barrow-loads of loam may be added to each cart-load, and be well mixed with the manure at the time it is formed into a heap to undergo the usual course of preparation prior to the making up of the beds.—A. W.

favourable in this respect we should advise you to lightly fork over the border and apply a light dressing of some stimulant, such as one of the many plant foods now on the market. Instead of this, weak manure-water may be given. The soil and temperature are very suitable, and we should not be afraid to open the ventilator immediately above it.]

Camellia failing.—Would you please tell me what is wrong with this Camellia? The leaves are turning brown. It was like this before I potted it last year. The mixture I used was loam, leaf-soil, sand, and manure. I have it in a vinery 3 feet from the glass, and it is flowering very well.—J. F. M.

[Undoubtedly the cause of the ill-health of your Camellia is some error in its culture. What that is we are unable to say definitely, and can only point out possible causes. We strongly suspect that the roots are in an unhealthy state, and the fact that you used manure in the potting compost would not tend to improve matters. A mixture of loam, leaf-mould,

easily satisfy our tastes and still keep to the varieties that are suited to the purpose. An arch or bower of Roses should never be formal or its main beauty is lost. Few things are more pleasing than an arbour or archway covered with the huge trusses of yellow and nankeen of Alister Stella Gray, the deep crimson of Carmine Pillar, or the creamy-white of Félicité Perpetué, more especially when the growths are allowed greater freedom than is usually met with. If we wish very hardy varieties for an exposed position, we should make use of the Ayrshires and others of the same habit, as Dundee Rambler, here seen clambering over an archway in Peckham Rye Park, Rêve d'Or, Zephirin Drouhin, Aimée Vibert, and Longworth Rambler. We can have flowers of small or large size, single or double; in large trusses; those producing a heavy mass of bloom early in the season, more or less continuous bloomers, or those almost evergreen.

FRUIT.

CHERRY BLOSSOM.

WE usually look Kent way for pictures of Cherry orchards, but judging by the following, from *The Times* of April 19th, other counties have charms in Cherry orchards:—

Every orchard in South Buckinghamshire, and the counties fringing on that district, is now a billowy mass of blossom. The trees are mostly of an enormous size, which accounts for the high, tapering ladders which are to be seen in this part of the world in the summer. In spite of late frosts and the cruellest of winds and blizzards, the Cherry trees are blooming earlier this year than last. For the past few weeks a deep pink shade has been diffused over every orchard—a sign that with warm rain and sunshine they would soon emerge into showers of white. But the cold winds persisted, and the rain came, but without warmth, and the trees burst into bloom amidst hail and sweeping northerly winds. So to-day the Cherry orchards stand out white against a background of purplish-red—for the other trees are not so forward—a wonderful Spring vision in a still wintry setting.

It is a sad sight to see some of the trees which were in leaf last year when the Cherry bloomed now lying prone, their great roots upheaved. In one Buckinghamshire orchard, where the Cherry trees are now white, there lies a whole row of giant Elms. Last year, when the orchard was in bloom, these same trees were thick with tender leafage. This Cherry blossoming country is full of the haunts of poets; it is the country where Milton lived; where Waller was born, in the windy hamlet of Coleshill, above Amersham. Hard by is the quiet retreat of the Quakers—of William Penn and his circle. Near Jordans, where rest William Penn and beautiful Gulielma, his wife, there is an orchard where the blackish trunks stand supporting showers of snowy blossom, and the green Grass beneath is chequered with moving shadows, as the blossoming boughs sway in the breeze. This orchard lies at the top of the steep, high hill which mounts from Jordans. Further on, past this orchard in the direction of Chalfont St. Giles, if one keeps on the high land above the Miskbourne stream, one comes to more Cherry trees, for that narrow lane leads through the heart of the Buckinghamshire Cherry Orchards.

NOTES AND REPLIES.

Grape thinning.—This now requires almost constant attention. One most important point in Grape thinning is to commence early. It is surprising how quickly the berries increase in size when the flowers are fertilised, so that if one does not begin to thin the most advanced bunches directly they require doing, by the time one has reached the last bunches the berries have developed so much that it is practically impossible to remove those one ought without damaging in some way those remaining. Begin thinning at the bottom of the bunch and work upwards. Take out all inside berries, cross berries, and small berries first. The berries left should be the big ones that point straight out. The berries should be left about $\frac{3}{4}$ inch apart. Be careful not to rub the berries with your head or anything else, because this injures the bloom and makes

the Grapes shiny when ripe. Do not put the scissors through the bunch to thin the other side, but move round the bunch. Cut the stalks in close, and keep the scissors clean.—G.

Caterpillar among Gooseberries.—Generally, the worst attacks are experienced during a dry season. There are many remedies—many of which are dangerous—but nothing is better than the old plan of dusting the bushes freely with soot, or with soot and lime in equal proportions, as soon as the first signs of the pest become visible. These, it will be noticed, are usually at the bottom of the tree, and if the infected part be at once dusted, the caterpillars will fall to the ground, where a good sprinkling of soot will speedily finish them. The summer rains will wash the fruit clean before ripening time comes round.—KIRK.

GARDEN FOOD.

SALADS FOR 1916.

THE season is coming when we may expect to have good salads in our gardens for those who do not force, and salad is such a precious element of garden food that we may well take some precautions.

It seems to me the great thing is to have salads as far as we can clear of manure of any kind, or with only a very small quantity of rotted stuff below the surface. It should be easy in every country place to grow salads in a cleanly way, and free from contact with any kind of manure. Clean, fresh ground, plenty of water, and such leaf soil as we can get where nourishment is wanted, is the best way of growing them. The introduction in many places of the French system of market gardening, that is to say, with beds on enormous mounds of manure, is very successful in the region round Paris, but I doubt if it is as well done in our country. If size is not to be desired in salads of any kind we ought to be able to get them in the freshest and best way without the addition of rich manure. All those who grow and control their own salads have the great privilege of being saved from the accidents of the market gardener and the market.

The way recommended in books of washing and drying salads is a mistake. Salads are better served as they grow, that is to say, as dry as may be. In that way we get the true flavour and the natural salts of the plants. Adding dressings, particularly what are called salad dressings, as is done in some English houses and in most hotels, is also a mistake. It is an odious delusion, but easily got rid of, and even we think an epicure of salads would be better without the best oil and vinegar. As to our great favourites, the Cos and the Cabbage Lettuces, it is possible that there are other things as well, and a man who has been going round the country lately in robust health made salads of all vegetables, getting rid of the cook and doing very well. He grated his Turnips and his Brussels Sprouts, and so on. Whatever we may think of his way there is no doubt that some delicate salads can be made of mixed fruits—Oranges, Bananas, and other things, helped out with good Apples like the Newtown Pippin. W.

NOTES AND REPLIES.

Qualities of dessert Apples.—The article from "F. B.," in your issue of March 11th, reminds one that we all have our preferences as to fruits and our special ideas as to the relative values of the many varieties. I offer mine. Ribston is dry, deficient of flavour, and of no value beyond October on this warm, gravelly soil. The following are all good for late use:—Allington, when well coloured, is good during December and January for those who relish briskness; Northern Spy is of

superlative texture, and useful right through March; while Bedfordshire Foundling will supply the lover of tartness during March and April with a good Apple. Something of richer flavour is found in Mannington Pearmain and Pine Golden Pippin during the first three months of the year. I should not like to be without some of the varieties marked kitchen in the nurserymen's lists. Highly-coloured fruits of Cox's Pomona during November and December, Beauty of Kent from February to April, and Northern Greening during March and April are refreshing in an unequalled degree; Carter's Pearmain is very pleasant eating during April and May, it is crisp, juicy, and rich; Sturmer Pippin finishes the season, being good right into June, but is tougher and not so sweet as Carter's Pearmain.—WILL TAYLER, *Hampton, Middlesex.*

Kirke's Plum.—Among dessert Plums this has, I consider, few equals. It has not the exuberant growth of some other Plums, and therefore needs much less pruning—an operation which ought to be very sparingly performed on all kinds of Plums. Its spurs never attain to an obtrusive length on walls, and it ripens up its wood well if the autumn is at all favourable. Kirke's may be relied on year after year to furnish a crop. Its fruits, too, are large and handsomely shaped, their purplish-blue skins, with delicate bloom, showing well in the dessert. The yellow flesh, as in all yellow-fleshed Plums, is of high flavour. In our northern climate this variety must have a wall, doing equally well here either with a southerly or an easterly exposure.—W. McG., *Balmac.*

The Pecan Nut.—The Pecan is one of the finest of Nature's products. One lb. of Pecans contains more nourishment than any other known food; 1 lb. of Pecans contains as much protein as $\frac{1}{2}$ lb. of meat, as much fat as $\frac{3}{4}$ lb. of butter, and as much starch or carbohydrates as $\frac{1}{4}$ lb. of bread, so 1 lb. of Pecans is the full equivalent of $1\frac{1}{2}$ lb. of other highly concentrated and nourishing food. In comparing total values, 1 lb. of Pecans is worth, in nutritive value, 2 lb. of pork chops, 3 lb. of salmon, 2 $\frac{1}{2}$ lb. of turkey, or 5 lb. of veal. An acre of land planted to Pecans will produce from four to ten times as much nourishment as one used for pasture. In the next century Nuts will largely, if not entirely, take the place of meats on the bill of fare, and the Pecan will assume its rightful place at the head of the list of nourishing and digestible foodstuffs.

Wholemeal gem bread.—1 lb. flour, $\frac{3}{4}$ pint water. Put into mixing-bowl cold water (boiled or distilled if preferred), and half the flour. Mix well together with whisk or hand. Mix in remainder of flour a little at a time until stiff enough to mould into gems. Drop into well-greased gem pans, which have been previously heated, and bake in a quick oven from forty minutes to fifty minutes. A "gem" is a small oval roll, about 2 $\frac{1}{2}$ inches long and 1 inch in thickness. If so made that a good deal of air is incorporated with the dough the gems, when baked, will be light, pleasant to eat, and very digestible.

Apple Claygate Pearmain.—I see this Apple much praised by readers. Once I tasted it delicious at Berkeley, but I think it is an Apple of very ordinary flavour. Some nurserymen have no doubt the true Apple, which is a very fine Russet.—S.

Birch wine.—Can any reader give me a recipe how to make Birch wine? It is the sap drawn from the Birch-tree. I think I saw a recipe some years ago in your paper, and I am not sure whether one should add sugar and yeast or only sugar when the sap is in the bottles.—F. A.

TREES AND SHRUBS.

THE PINASTER AND THE STORMS.

I HAVE a notion that the Pinaster is a neglected tree, and very much more valuable than some of the fashionable Conifers of the day. There appear to be varieties of it, some better than others. At any rate, there are some extraordinary trees of it in Sussex which have withstood the storms for many years. I wrote to the owner to ask him how they stood the recent gale, and this is his answer. They are very handsome trees, and I am pleased to hear that they survived:—

In reply to yours of April 11th, I am

fore May, if the bloom is susceptible to damage by frost, is of any use with me, and the earlier May blooms are caught as often as not. Several of the quite late bloomers were caught last year, but that we must hope is exceptional. W.

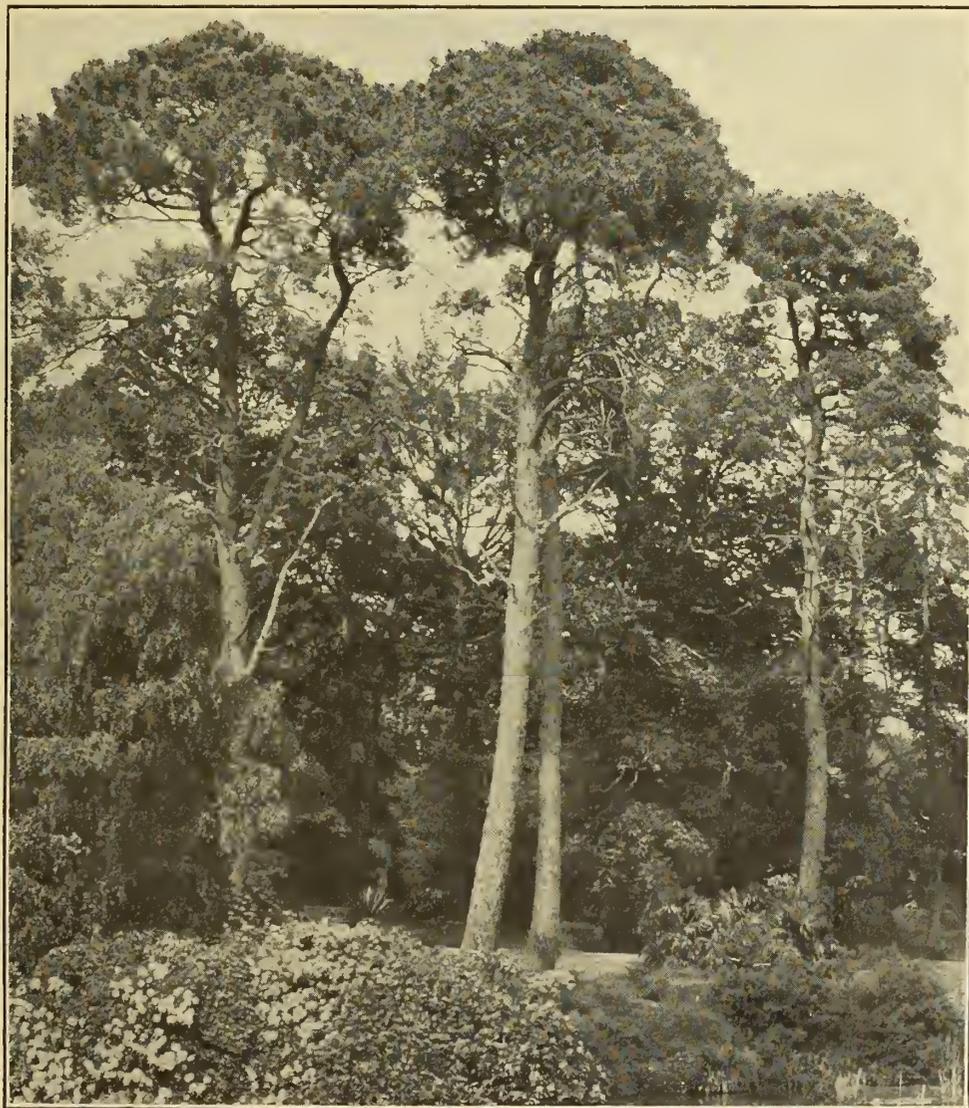

NOTES AND REPLIES.

Shrubs for bank.—I have a small shrubbery, the bank on pathway running up into shade of tall trees. Would the Tamarisk be suitable to brighten up the place?—T.

[Very few shrubs are likely to succeed on a bank under tall trees. Certainly the Tamarisk would not be a success under such conditions, as full sunshine is necessary in order to develop the charming pink

named is the Ivy. For such a purpose the smaller-leaved forms, if of free growth, are preferable to those with large leaves, which would, from the weight of their foliage, be very liable to be stripped off by heavy gales.]

Cutting Ivy.—The common Ivy is the best of all evergreen wall climbers, for it is at its best during the dark, dreary days of mid-winter, and gives a snug, warm look to any building that is covered with it. Like all other creepers of a strong growing nature, it needs frequent attention to keep it in order, or it will fill up water-spouts and over-grow windows if not kept in check by timely pruning. It must have at least one good cutting-in

Group of Pinaster, Sussex.

very glad to say that my big Pinasters escaped anything but quite trifling damage from the south-westerly gale of the one night and the northerly blizzard of the next. In fact, I escaped very fortunately altogether, but the gardens are so well sheltered on the northern side that we never suffer from that direction. I hope you have been equally fortunate. I see the winter has left its mark upon some of my Eucalypti, or, rather, the autumn, as it was, I think, the November frost that did the damage. The early Rhododendrons have not had a ghost of a chance this season, but it is very seldom they have, and I consider that nothing that blooms be-

colour of its blossoms. Furthermore, it would not thrive in such a position. Of the few subjects that may hold their own under the conditions named, the most likely are the Butcher's Broom, Berberis Aquifolium, and Berberis Darwini, and of low-growing shrubby plants, the Ivy, Vinca minor, and Hypericum calycinum.]

The Hydrangea.—Will the Hydrangea stand gales of great violence where shelter is impossible on sea coast?—K. B.

[The Hydrangea would not be likely to succeed under such conditions.]

Hardy self-clinging creeper.—What is the hardest evergreen creeper, self-clinging, for walls exposed to terrific sea gales? The soil is poor.—K. B.

[The only self-clinging evergreen climber likely to succeed under the conditions

every year, and I find that April is the best time for doing it, for then the season of active growth is close at hand, and the young foliage quickly develops and takes off the somewhat bare look given it by clipping. A small, sharp reaping-hook or pair of pruning shears is the best tool for cutting it in with, and it should be cleared entirely off the wall below the gutters for at least 1 foot, or it quickly fills them up and causes an obstruction.

The Double-flowered Blackthorn (*Prunus spinosa* fl.-pl.).—Well-flowered examples of this shrub at once arrest attention, for the white blossoms are conspicuous, and last in good condition for a longer period than those of many other kinds of *Prunus*. The stiff, spiny branches peculiar to the type

are reproduced in the variety, and there is little to distinguish between the two plants when out of flower. The blossoms, which appear in April, usually with great freedom, are each about one-third of an inch across. As is the case with the type, this variety is well adapted for planting in poor ground, and this, together with its showy nature, should be sufficient recommendation for its extended culture. Unfortunately, it is not easily obtained, probably on account of its having to be increased by grafting. It is sometimes offered grafted on stocks of the type a few feet high, and at other times it is met with as a low bush with branches touching the ground. If it could be obtained in quantity it would form an excellent companion to the double form of the common Gorse for clothing dry banks, while it is equally worthy of a place among choice shrubby plants.

The Snowdrop-tree (*Halesia tetraptera*).—One of the most beautiful of flowering trees in its season is *Halesia tetraptera*. Introduced as long ago as 1756, it is still by no means so extensively grown as its beauty warrants. It is perfectly hardy, and, given a rich, open soil, and abundant moisture, makes a charming display in April. I have a tree, every year crowded with flowers, which is 15 feet high and more in breadth. The popular name of Snowdrop-tree is a particularly appropriate one, for the pure white pendent flowers, which thickly stud the old wood, have a close resemblance, both in shape and pose, to those of our native Snowdrop. They are borne in clusters of three or four on short stalks. The specific name refers to the four-winged fruits. The tree is deciduous, the leaves just pushing after the flowers have expanded. The species is a native of South Carolina, etc., and likes more especially the banks of streams and other moist situations.—F.

OUTDOOR PLANTS.

SOWING ANNUALS.

As the best time for sowing these is now with us, it may not be amiss to call attention to one or two facts that are frequently overlooked in their culture, and which, to a great extent, bring them into disrepute. The first cause to which I allude is that of sowing them on poverty-stricken soil, thereby causing not only a very meagre, but also a very short-lived, display of bloom. Sowing thickly is one of the worst things that can be done. It is a very common practice to sow annuals in patches in mixed borders, and generally one can find from ten to twenty plants in a space where three or four would make a far more effective display. If it is desirable to sow in patches it is certainly desirable to sow more than enough seeds to form a good clump; but as soon as the plants are large enough to be considered safe from the many mishaps that befall the seedling plants they should be thinned out to the desired number, which can reasonably be supposed to attain something like a full development. I am aware that a good many annuals do better sown where they are to flower. These ought to be treated as above described. A good many may be sown in boxes, pots, or pans, and planted out when other bedding plants are put out. I may mention *Phlox Drummondii* as one of the most popular annuals grown, and one that has been immensely improved of late years. The very best strain of seed is far more expensive than the old small-flowered one, but a small packet of it, if sown in a seed-pan or box, and the seedlings pricked out singly as soon as large enough, and finally planted out at least

1 foot apart, will fill a large bed as they branch out, just the same as *Verbenas*; and if regulated over the surface with a few pegs or hair-pins before they come into bloom will make a really magnificent display. Plenty of other illustrations might be cited, for in the main the transplanting of seedlings singly is amply repaid by better after results. Then, as regards soil, how often do we see annuals sown in borders full of the hungry roots of coarse-growing herbaceous plants that suck out every particle of nutriment, and where it is difficult for the seedlings to live at all, much more thrive, so as to attain anything like fair proportions. Only give annuals fair play by planting them in good soil, deeply cultivated, and they will hold their own against anything in the whole list of garden flowers. Briefly, get the best seed, sow thinly, and plant out where they can flourish, and your beds of annuals will yield you infinite pleasure. T. P. W.

THE MAYFLOWER

(*EPIGÆA REPENS*).

"SURREY," p. 189, wishes to know under what conditions this hardy plant thrives. I have never attempted to grow it because I know that I could not possibly give it the conditions which are indispensable to its welfare unless I adopted means which I think are out of place in the case of hardy plants. For me a hardy plant has no value if it has to be protected not only against the vicissitudes of an English winter but has to be nursed during the growing season. When the late Mr. Wilson began growing hardy plants at Wisley this *Epigæa* was one of the things that he much desired to establish. He failed for some time, but one day he showed me with pride a plant which was unmistakably at home. It was in short Grass just within the shelter of Oak-trees, the over-hanging boughs of which gave a certain amount of shade. "You see," said Mr. Wilson, "it is rooting as it goes," and unless one can get it to form roots in this way it will certainly not become thoroughly established and will not take on perennial vigour. Later on I saw it in a most luxuriant condition in the Oak wood in company with Lilies and other things which cannot be treated as border plants, and I cannot imagine that it would be more vigorous in its native land. The soil, naturally light, was enriched by the accumulation of decayed foliage which had been going on for very many years. This must be the natural rooting medium of this *Epigæa*, and, in conjunction with the shade, shelter, and atmospheric conditions engendered by the superior vegetation, gave it exactly what was necessary to promote a vigorous life. Only where this hardy plant finds similar conditions can one realise its beauty. It is a charming hardy plant when in its native vigour, but in the form of semi-stunted specimens, such as are generally to be seen, it is not worth growing.

"Surrey" and others who may be interested in this hardy plant will, I think, realise what it needs, which briefly stated are partial shade and very free soil composed mainly of decayed leaves and perfect shelter from cold winds. Those who have woodland should have no difficulty in growing this interesting little hardy plant to perfection. If shade and shelter are there the rooting medium can be made, in which case I would suggest well-decayed leaf-soil and some peat in lumps. It is, of course, open to those who have no woodland to try their hand, in which case a north position should be chosen and dryness of atmosphere must be neutralised as much as possible by frequent moisten-

ings both at the roots and overhead. In this way a moderate degree of success may be achieved, but not comparable with that obtained under conditions which closely imitate those which it enjoys in the woods of New England. J. CORNHILL.

NOTES AND REPLIES.

Montbretias wintered in cold-frames have made sturdy growth. They have been hardened off, and may now be planted out. The ground where it is intended to form groups should have plenty of old hotbed manure or leaf-soil trenched in. For grouping, the plants may be placed 6 inches apart, at which distance they form masses of colour. If a border is devoted to their special culture, plant in rows 1 foot apart and 6 inches apart in the rows, this allowing room to use a hoe amongst them.

Double White Rocket.—For many years I went to a great deal of trouble to obtain the real old-fashioned sweet-scented double White Rocket, and tried specimens from many nurseries. However, I have at last obtained the correct kind, and shall do all I can to preserve it by taking side shoots every year and striking them, otherwise I believe the plants die off.—HOLLIES.

Hunnemania fumarifolia.—Although perennial, this is so tender, except in very warm gardens, that it is best treated as an annual. It is much too seldom grown, and is really a handsome and showy border flower.—S. A.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

PRIMULA DENTICULATA.

AMONG the bolder and more showy hardy Primulas none is more easily managed than the subject of the present note. Rich in variety and well grown in informal groups, it commands attention by the effectiveness of its display at flowering-time. Good as a border plant, it may be introduced into the cooler parts of the rock garden with every hope of success, the measure of success depending on a more or less generous treatment. The accompanying illustration shows a small group of it in the rock garden, to which reference has already been made, and in such a place it is seen to advantage.

What surprises one, seeing its free seedling and the ease with which hundreds or thousands may be raised, is the comparatively little use made of it for naturalising in cool or moist woodland and like places; in short, where our native Primrose—most precious of spring flowers—in established examples bearing nearly foot-long leaves and tufts in proportion, revels. In these and places akin this Himalayan kind would need but little soil preparation to make it a success. Not that I would suggest any slovenly method of treatment or haphazard way, the plant meriting something more than this. In the woodland the plant would not only show well, but be benefited by the shelter afforded—a substitute, in some measure, for its own native covering of snow. For such work seedlings would be best raised in boxes and put out when three or four leaves had been formed. In Nature the species often inhabits boggy or wet ground, and in cultivating it the fact should be borne in mind. A deciduous kind, resolving practically into a crown at ground-level in winter, the vagaries of our climate tempt it occasionally to start early into growth, with the result that the flowers are injured by frost, though rarely to any great extent.

SEEDLING-RAISING of this fine perennial kind is especially interesting, because of the good colour forms that are likely to occur. Lilac in the typical kind, the usual range is from the palest of this shade to rich, sometimes reddish, purple and white. The varieties differ also in size of flower, all being produced in roundish heads at the top of a foot-long scape. The pure white form, *P. denticulata alba*, is especially valuable for the alpine-house. It also

comes fairly true from seeds, though tinted lilac forms also appear. Possessed of a greater vigour, and more imposing withal, is the Kashmir form, *P. d. cashmiriana*, a variety also characterised by longer leaves and more richly-coloured flowers. The whole plant, too—stems, leaves, and calyces—is covered with a dense meal. The coming of this excellent variety about the year 1879 gave a distinct impetus to hardy plant gardening at the time. Seeds of it and the equally unique *P. rosea* were distributed in the same year—both acquisitions to the cultivated species of that time and not surpassed to-day.

Primula seed is best sown soon after ripening, little soil covering being necessary. Delay in this is frequently accompanied by loss of vitality; also uncertain vegetation. A point for the seedling-raiser to bear in mind is the bog-loving nature of this set. Moisture, indeed, is as important at this as during the growing stage. The raising of these plants from root-cuttings in the case of plants so easily and abundantly raised from seeds is likely to suffer neglect or fall into disuse altogether. It has a value of its own, however, in the case of varieties of special merit, the plants then coming true. It is, however, less expeditious than seedling-

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM APRIL 20TH.—*Osoberry* (*Nuttallia cerasiformis*), *Forsythias*, *Rhododendrons* (in variety), *Purple Plum* (*Prunus pissardi*), *Rosebud Cherry* (*Prunus pendula*), *P. Amygdalus*, (the *Wild Cherry*), *Ribes sanguineum*, *Osmanthus Delavayi*, *Andromedas* (various), *Viburnum Carlesi*, *Cydonias* (in various colours), *Chinese Quince*, *Elæagnus edulis*, *Berberis* (in variety), *Prunus triloba*, *double Gorse*, *Laurustinus* (various), *Azara microphylla*, *Rubus spectabilis*, *Bush Honeysuckle*, *Sweet Gale* (*Myrica Gale*), *single and double Camellias*, *Ericas* in great variety, *Spice Bush* (*Lindera Benzoin*), *Spiræa arguta*, the *Pearl Bush* (*Exochorda grandiflora*), *Magnolia stellata*, *M. conspicua*, *M. Soulangeana*, *Pernettya serbica*, *Narcissi*, *Snowflakes*, *Grape Hyacinths* (in variety), *Windflowers* (in variety), the *Pasque-flower* (*Anemone Pulsatilla*), *Hepaticas* (in variety), *Primulas* (in variety), *Polyanthuses* (in variety), *Saxifrages*, *Barrenwort* (*Epimedium*) (in various colours), *Arenaria balearica*, *single and double Arabis*, *Scillas*, *Hutchinsia alpina*, *Bloodroot* (*Sanguinaria canadensis*), the *Algerian Iris*, *Honesty*, *Stylophorum diphyllum*, *Water Hawthorn*, *Fritillaries* (in variety), *Snow Glories* (in variety), *Red and yellow Fumitory*, *Forget-me-nots*, *Hyacinthus azureus*, *Tufted Pansies*, the *Greater Celandine*, *Caltha polypetala*, *C. palustris*, *Violet Cress*, *Crown Imperials* (various), *Lithospermum Heavenly Blue*, *Veronica filiformis*, *Gentiana verna*, *Arctostaphylos californica*, *Collomia grandiflora*, *Anchusa myosotidiflora*, *Synthyris reniformis*, *Omphalodes verna* (white and blue), *single and double Primroses*, *Pernettya serbica*, the *Bitter Vetch* (*Orobus vernus*), *Wallflowers*, *Tulips*.

WORK OF THE WEEK.—The final sowing of

(Ruth Fischer) makes a charming carpet to beds of red or yellow Roses. *Viola gracilis* has been used for this purpose. This lovely plant flowers itself to death here, and care is needed otherwise the whole stock would disappear in summer. Mowing has been left later than usual this year for various reasons, and the Grass having grown too long in places the scythe has had to be used in advance.

Sussex.

E. M.

SOUTHERN COUNTIES.

Outside Vine borders.—The winter covering may now be removed in order that the sun may warm the border and induce activity among the roots near the surface. After the covering has been taken off and the surface cleaned, the latter should be dressed with a concentrated Vine-manure, lightly forking in the same afterwards. A mulch 2 inches deep of horse-droppings, spread evenly over the surface of the border, will then render the operation complete. Failing material of the nature mentioned with which to mulch the surface, short litter may be employed instead.

Early Peaches.—With the completion of the stoning, which is best ascertained by taking a fruit from each tree and cutting it open, the crop must be reduced to safe proportions forthwith. The old-established rule of allowing one Peach to each square foot of trellis clothed by each tree is a safe one, and is always adhered to. Nectarines are left somewhat closer, or one fruit to every 9 inches square. Such of the fruits as are inclined to hang downwards should be elevated on pieces of lath, so that they shall get the full benefit of sunlight and become well coloured at the finish. As the skins of Nectarines are apt to burn if exposed to intense sunlight about the time they begin to soften, that portion of the roof under which the trees are situated should then be lightly shaded with whitewash. They will then ripen perfectly and without blemish. Higher temperatures may now be safely indulged in, that for the day ruling from 70 degs. to 75 degs., and from 60 degs. to 65 degs. at night. Advantage of sunny weather may always be taken to close in time to secure a temperature of 85 degs. to 90 degs. The watering of the border must now be carefully attended to. This is all-important, as, if the soil is allowed to become at all dry and a heavy watering follows, the sudden accession or flush of sap is apt to cause splitting of the fruits—particularly Nectarines—to take place. Although a final dressing of artificial manure is given when stoning is finished, liquid stimulants are admissible up to the time the fruits exhibit signs of ripening. Until that stage is reached the foliage must be liberally syringed daily, and as soon as warm weather sets in the syringe may be superseded by the garden engine. Due attention has to be paid also to the tying down of the young wood when necessary, and in the pinching of lateral growths and all those which extend beyond the limits of the trellis.

Second house.—A final thinning of the young wood should now take place, leaving, as far as circumstances permit, no more than is necessary for future requirements, as well as to secure an even spread of foliage without any crowding. A further thinning of the fruits may also be done, leaving the final thinning until the stoning period—upon which they are now entering—is safely passed. Matters of routine, such as keeping the young growths tied to the trellis, airing liberally on fine, warm days, keeping the foliage clean and free from insects by that best of all insecticides copious supplies of water applied forcibly, must have due attention. If fly should, unfortunately, effect a footing, afternoon syringing would then be omitted, and the house vaporised at night. A vigorous syringing the following morning would clear off any of the insects which might not be killed outright. A thorough watering of the border now will carry the trees through until the stones have become perfected.

Celery.—Seed of the variety *Leicester Red* will now be sown to yield a good lot of plants to come in for late supply next spring. A good quantity of *Solid White*, *Superb Pink*, and *Sulham Prize* will be pricked out into frames in which Violets have been grown during the winter. The loamy soil which was placed therein for Violets does admirably for Celery, as good balls of soil attached to the roots are certain to result from the use of such material. The only preparation required is to level and make the surface firm and to put a little fine soil on top into which to prick off the plants. After having been watered, shaded, and the frame kept closed for a few days, the plants soon start growing, and can then be freely aired to ensure sturdy growth.

Early Potatoes.—A sharp look out has to be kept to prevent the tops being injured by frost, as they are now on the point of pushing through the soil. The best preventive is to pass up and down the rows, and with a hoe to draw up sufficient soil to all that are visible to cover them. This, at any rate, places them out of harm's way for a time.

Maincrop Carrots.—The sowing of these has at last been accomplished, the soil, fortunately, being caught in good working condition after several delays. The soil being of no great depth, an intermediate variety has been selected.

A group of *Primula denticulata*.

raising. The work should be done during the winter.

E. H. JENKINS.

NOTES AND REPLIES.

Moving rock plants.—I am moving to another house in June. Can you advise me as to moving my small collection of rock plants? These, though not numerous, consist of a great many varieties. I have possession now of a new garden close by, and could move them now, or I could leave them where they are until the end of September and move them then. Would it answer to move them now to a prepared bed and leave the making of the rock garden till later, and finally plant it in the autumn? This would be the easier plan for me.—G. C. PHILLIPS.

[The simpler and better plan would be to move them now, particularly as the opportunity for so doing is open to you. In moving the collection it would also be well to divide the plants, so far as that is possible, transplanting the units with room for developing. By so doing and by affording the plants a full season's growth ahead, there should be available not only a considerably increased stock of plants, but reinvigorated examples of a youthful nature, capable of a better service than could possibly result from the planting of older specimens transplanted intact. All the same, you would do well to push forward the building of the rock garden, so that the planting may be done during September if possible.]

flower seeds under glass has been made, and many of those sown in March have been pricked out into boxes. Perennials raised in the same way are given all the air possible in order to harden them before planting out. The vacant spaces among shrubs are now being prepared for hardy annuals. The ground is heavy, and, therefore, entails considerable labour to break it down sufficiently to allow a covering of fine soil for the small seeds, which we hope to sow during the coming week. A row of *Pernettyas* planted during the winter which had become drawn and straggly has been cut hard back. A group of white Lilacs on their own roots has been planted out in the Heath garden, and a further group of *Butcher's Broom* has been made near those recently put out. Some plants of *Prunus pissardi* (Wood's variety), having come to hand, have been put out in the Heath garden among young *Box* bushes. Young plants of *Daphne Mezereum* have been used to thicken an existing group. This is not very happy in our soil, preferring that of a chalky nature. The *False Heath* (*Fabiana imbricata*) has not been very satisfactory owing to the poor condition of the soil where it has been growing, and so a new plantation has been made in richer ground.

Sweet Peas raised in pots, after a thorough hardening, have all been planted out on well prepared ground, some in groups and others in long lines. After planting, a dusting of soot was given and the plants staked with small Birch sprays, which give a little protection from the cutting winds as well as support. After the Peas have become established 10 feet stakes will be used. A large group of *Fellenberg Rose* has been carpeted with the *Giant Summer Forget-me-not*, and the planting of other Rose beds with various coloured *Tufted Pansies* and other plants is being continued as weather permits. The dwarf *Forget-me-not*

Chicory.—This is best sown under similar conditions to the foregoing, and to ensure good, stout roots the plants should be thinned to 9 inches apart. This allows ample space for each to develop properly.

Beet.—Seed of the long-rooted Beet will be sown the first favourable opportunity. In its present condition the soil is too hard and dry for a good tilth to be secured, but after a light shower or two it will then break down to a fine state and form a good seed bed. The drills will run north and south, and stand 1 foot apart. Three or four seeds will be dropped at every 9 inches into the drills, and the plants thinned down to one when in fit condition for this to be done.

Scarlet Runners.—The site where the rows will be grown will now be prepared. For this purpose narrow trenches are opened and good rotten manure placed in the bottom about 4 inches deep. This is trodden firm and over it sufficient of the best of the soil thrown out is spread to bring it up to ground level. The surplus soil is placed on either side of the trench, which converts the latter into a kind of broad furrow, and renders it capable of retaining water, when necessary to apply it, without any waste ensuing. Grown on this principle the roots are to a great extent rendered proof against the vicissitudes of a hot, dry summer, and the plants continue yielding long after those grown in the ordinary way have ceased to be of any further use. The seed is sown in a double row as soon as the soil has settled down. A. W.

MIDLAND COUNTIES.

The earliest Peaches are swelling fast after stoning, and are afforded a rather higher temperature—65 degs. by night, 80 degs. to 85 degs. by day with sunheat. The trees are syringed morning and afternoon, and the atmosphere of the house kept moist. Untie any shoots that press the fruits against the wires or shade them from the light. Syringing must be discontinued as soon as the fruits begin to ripen. See that the trees do not lack water at the roots, and give liquid manure to those that are heavily cropped. Succession Peaches are stoning, and the temperature is not allowed to exceed 60 degs. by night, free ventilation being given during the day when the weather is favourable. The shoots are tied down as they grow, being careful to avoid overcrowding. Any extra strong shoots are stopped to balance the flow of sap. The trees are kept free from aphid by occasional fumigation with nicotine compound.

Vines require to be looked over once or twice weekly, stopping all lateral growths that are extending beyond one leaf, and those in later houses to one or two joints above where the bunches are showing.

Peaches and Nectarines are ready to be again disbudded, and all shoots necessary to be retained for the building up or extension of the trees will now have to be selected. It is well to leave two of the best placed at the base of each branch until one of them gets a good lead and can be tied in. Let these spring from the upper sides of the branches nearest to the centre of the tree. Trees trained on this principle are more uniform in growth, cover the walls better, and are much easier to regulate should a branch die. The remaining shoots on the branches should be further reduced to 3 inches apart for the present, preserving at the same time all the best placed and strongest fruits. Take means to prevent aphides from increasing among the young leaves. Quassia extract is the safest remedy, and should be applied as often as necessary. Some varieties of Peaches are liable to be attacked by mildew, and whenever this appears the affected trees should be syringed with a weak solution of Gishurst compound, using about 2 oz. to 1 gallon of water, allowing it to remain on the leaves. All insecticides should be applied to the trees in the evening and in fine weather, for the foliage of the Peach being very tender at this date is easily injured. At the time of writing the protecting nets are still left on the trees, cold north-east winds such as we are experiencing conducing to mildew and the attacks of aphides.

Cherries do not require much disbudding. Merely remove those shoots which spring from the back of the branches and thin those growing in clusters to prevent overcrowding, training in sufficient for the extension of the branches or for renewing worn-out shoots and furnishing blank spaces. All other shoots should be pinched at the third leaf. Cherry-trees are very subject to attacks of black-fly, and on its first appearance means must be taken to destroy it by syringing with an approved insecticide.

Herbaceous borders.—Many early-flowering subjects, as Delphiniums, Lupines, Paeonies, Galegas, Heleniums, Oriental Poppies, the larger Campanulas, etc., will now need support. It is not necessary or desirable to stake everything, only those especially liable to injury. For plants in groups I find a few sprays of Pea-sticks placed around and among them quite sufficient, and by the time they reach the flowering stage the plants practically hide up all the sticks. Eremuri in a sheltered position are now pushing up their flower-spikes. It is advisable not to tie these flowers up to sticks, as the stems being very brittle

are liable to be snapped off just above the stakes by rough winds. A good mulching of manure has been afforded them, and in dry weather they will be greatly benefited by copious supplies of water.

Polyanthuses raised from seed sown in boxes are ready for pricking out into nursery beds on a cool border. There are now many fine strains which come fairly true from seed. The present is a suitable time to sow seeds in a cool spot out-of-doors.

Hyacinths and Tulips cleared from the beds in time to make room for summer-flowering plants are often regarded as worthless, but all they need to make them serve again is careful lifting and replanting. Put them somewhere in the open, and water occasionally, so that the leaves may ripen off naturally. I find that bulbs so treated ripen up well and flower the next year.

Perpetual-flowering Carnations.—A batch of plants that has been flowering indoors all the winter will be planted out on a well-prepared border. Here they will continue to flower all the summer and make good growths for propagating in September.

Early-flowering Chrysanthemums will be planted out at the first favourable opportunity.

Roses.—It is necessary to keep a sharp look out for maggot and aphid as the plants need close attention to keep them free of these pests, which if neglected quickly cripple the most promising buds and shoots. Aphid is quickly checked by syringing with Quassia extract sometime during the afternoon; but in dealing with the maggot the surest plan is to give the curled leaves a gentle squeeze with the finger and thumb, after which syringe with the above-mentioned insecticide.

Thinning crops.—One of the greatest mistakes that can be made in the cultivation of vegetables is overcrowding. Especially does this apply to Peas and Beans. These are often sown and permitted to grow too thickly, the consequence being the plants crowd each other and the yield is poor and of short duration. Thinning should be done as soon as the seedlings are large enough to pull out, and all small crops, as Onions, Parsnips, Turnips, Beet, Lettuce, etc., should be thinned out twice. Keep the ground stirred between the lines with the Dutch hoe, and dust over the ground frequently but lightly with fresh soot, which is not only one of the best stimulants to apply at this season, but protects the above-named crops from the ravages of birds and other pests.

Lettuce, both Cos and Cabbage, is now sown frequently, planting out from each sowing, so that no break in the supply is likely to occur. Lettuce should be watered freely in hot, dry weather, thus ensuring a quick, crisp growth.

F. W. GALLOP.

SCOTLAND.

The greenhouse.—*Cineraria stellata* has been very effective, but the plants now show signs of exhaustion. Flowers still in comparatively good condition were cut, and a few of the best of the plants were for a time retained. To fill up the space thus vacated use has been made of a good batch of *Schizanthus Wisetonensis* now in excellent bloom. The plants having been grown quite cool are robust, and will be useful for some time to come. Another useful subject, in the shape of the winter-flowering *Antirrhinum Nelrose*, has also been employed, the spikes of this useful variety lending variety. A large batch of *Zonal Pelargoniums*, too, was made use of. These are chiefly in 6-inch and 7-inch pots, and if assisted with liquid manure they will bloom freely until autumn is well advanced. A final lot of double-flowering *Begonias* was boxed up for late use, and plants of the same family now some way advanced were reported. These are grown to some extent, and are in many shades of colour, but whites are strictly limited in number, as it is considered that they are singularly ineffective either in groups or when used singly. A good quantity of *Campanula isophylla* and *C. l. alba* also received a shift from 3-inch pots into 5-inch pots, in which handsome pieces which bloom profusely can be grown. *Primulas* yet remain in good condition, and during the week a number of seedlings of *P. obconica* was pricked off for autumn blooming. Watering now takes up a considerable amount of time, and as far as possible this is attended to in the early morning. With more sunheat firing is now less essential, although a little heat is still run through the pipes at night.

Stove.—Syringing is now regularly done twice daily—early in the morning and round about 4 p.m. In order to reduce firing, early shutting up is practised, and if the thermometer rises rather sharply no harm follows when the house has been thoroughly damped down. *Gloxinias* come on apace, and the batch for September work was potted during the week, as were *Gesneras* and some pieces of *Saintpaulia ionantha*. In the case of several large plants in pots top-dressing was given. This method serves well enough for a season, but as drainage cannot be attended to it is merely regarded as a makeshift. Recently-pruned climbers now making free growth are being tied in as becomes necessary. *Acalyphas* now strike readily if young growths are

selected, and in a small state these showy plants possess some value. For large baskets such Ferns as *Nephrolepis exaltata* and *Phlebodium aureum* are useful, and soon fill up if vigorous young plants are employed. Damp down freely the pathways and stages, for if a dry atmosphere is permitted *Crotons* and similar smooth-leaved plants will be liable to attacks of red-spider and thrips. This is a very good season at which to sow seeds of Palms. In the majority of cases germination is rapid, and young Palms are useful in many ways.

Begonia Gloire de Lorraine.—The last lot of cuttings has gone into the propagating case. Encouraged by the success which followed the cultivation of a spare batch during the past winter under ordinary greenhouse conditions, the plants resulting from these cuttings will be given cool treatment throughout their season after they have rooted. The plants referred to lasted in good order for an exceptionally long time, and long after those in a higher temperature were over.

Nerines.—These, being now sufficiently ripened, will be placed on a shelf fully exposed to the sun, and by and by they will be stood out-of-doors at the foot of a south wall until the autumn. Similar cultural details are applicable in the case of *Hamantails*.

Vallota purpurea.—Some good potfuls of the Scarborough Lily were in the course of the week top-dressed and removed from the cool-house in which they had passed the winter to pits, where they will remain until the flower-spikes begin to be visible, which under such conditions is generally about the beginning of September.

Figs in pots.—During the week Figs in pots have been top-dressed. These trees have been kept quite cool, and promise good crops. It is curious that while Figs out-of-doors succeed in poor sandy soil and a circumscribed root-run, it is hardly possible to provide too rich feeding for Figs under glass, whether these are in pots or planted out. Syringing is done twice daily. Stopping is practised at the fifth leaf beyond the fruit.

Vines ought to be looked over regularly and the shoots carefully tied down. A tight hand should be kept on sublateral growths. If these are not kept pinched the main leaves are robbed of nourishment, and not only so, but the roots are unduly excited, and when sublaterals which have been neglected are suddenly cut back a check ensues which may lead to shanking. The use of the knife is deprecated. Sublaterals ought to be removed at a stage when they can be pinched out between the thumb and forefinger. Present temperatures: For Hamburgs and similar varieties, 63 degs. to 65 degs.; Muscats, 5 degs. more.

Pricking off has claimed a considerable proportion of the available time in the course of the week. Much use is made of beds in cold-frames for this purpose, this being preferable to using boxes, however handy the latter may be at planting-out time. In beds watering is much more easily done and does not require to be attended to at such close intervals, while, if care is taken when the plants are lifted, good balls can be always secured. For some little time the sashes are closed rather early in the afternoon and matted up, but when danger from frost is over the frames will be freely ventilated by night as well as by day. In the course of the week large quantities of such things as *Antirrhinums*, *Marigolds*, *Tagetes*, *Asters*, and *Lobelia* have been dealt with.

Biennials.—The sowing of biennials, including *Canterbury Bells*, *Sweet Williams*, and so forth, has been attended to. In addition, several varieties of *Aubrietias* were sown. These will be pricked out into cold-frames for transferring to their flowering quarters in late September.

Melons in pits.—Seeds have been sown to provide plants for growing in pits. Meantime, the manure intended for the filling of the pits is being turfed and re-turned on alternate days in order to sweeten it. The right kind of manure for this purpose grows more difficult to procure, and more use has to be made of leaves. As, however, there are hot-water pipes in the pits referred to, it is not a difficult matter to keep up the temperature should the heat from the hotbed decline. A good, heavy loam is used, and a fair proportion of old mortar rubble is mixed with it. At the same time seeds of Cucumbers to be grown under similar conditions were sown.

Peaches and Nectarines on walls are yet being hand-fertilised, as, if a free set is wanted, artificial fertilisation must be undertaken. There are indications of a good crop, and presently some little disbudding will be done. There has been no serious frost so far, and the outlook is encouraging. Meantime, when the thermometer is very low, covering is done. Plums, too, are being similarly treated. Those on a south wall, Jefferson, Washington, Kirke's, and several Gages, are in fine bloom.

Kitchen garden.—Broken weather from the middle of the week onward prevented much progress being made. More Turnips were sown, a couple of lines of Early Nantes Carrot and a few lines of Broccoli. The Turnips and Carrots were sown on ridges of Celery trenches, from which they will be cleared off in plenty of time.

Balmie Gardens, Kirkcubright.

BOOKS.

"IN A COLLEGE GARDEN."*

THIS is a very well-meant and well-written book, but there is not much in it about gardening. Everyone must wish that all women who care for gardening may learn it, and the more women who find healthy occupation the better for them and for us all. At the same time, the idea which the author endeavours to propagate that until recently women were not interested in gardening is clearly a mistake. In Mrs. Loudon's day ladies were just as much interested in gardening as at any other time, and they had fewer distractions than they have now in the way of golf, hockey, shooting, and other pastimes, not excluding the cigarette. A party of young lady students came to see my garden one day and were observed taking a little relaxation on the Grass smoking cigarettes, one of the most active heart poisons.

A lady cannot know too much about gardening if she is to manage her own garden or even a small market garden. Gardening in a broad sense, such as we want in our country places, of which there are many in every county, is not sufficiently considered in this book, and the following points deserve thought.

The way to make a good gardener is the way that makes a good sailor, and that is, apprenticeship first. The conditions, the soils, and the fruits and crops grown in our country vary so much that no one can be properly taught gardening in any one place. The idea that gardening can be taught in a year or two at a self-styled college is a delusion.

THE WORK TOO HARD FOR WOMEN.—For quite half a year in our country the weather is far too severe for women to work in the open air. The soils in the Thames Valley and about Edinburgh and Dublin are often friable, but what about the heavy Wealden soils, or the cold clay north of London, 50 feet deep, and some about Horsham, where land is pure clay often. Only the strongest men can face such soils. Heavy work also as forming walks, trenching ground in all weathers, nailing trees on frosty mornings, planting fruit-trees, and other work is not for women, who ought to be occupied in the first place with work under cover. Men are often employed in shops and on work of many kinds which can be done as well by women, and would be much more agreeable work for them, as it can be done in all weathers.

This learning gardening in colleges is an arduous thing that very few women could face. We are told in the book that young women are given one week in which to decide what they will do.

"I now, therefore, invite the reader to follow me in the proceedings that take place when new students have been through a probationary week at the College and are called upon to decide whether they like the life and intend to remain two years in order to perfect themselves for the profession. It is customary for them to report themselves to their Principal, Miss More, and, being passed by her as competent for their future studies, they are admitted to my office, when I, as Founder of the College, am asked to give them some words of wholesome advice.

"The employer, meanwhile, is slowly learning a lesson, and begins to realise that to have a lady as a gardener is a luxury and must not be considered an economical way of reducing the payment of a living wage. A woman gardener, like all head gardeners, should be paid in proportion to the amount of brain-fag, deception, and other disagreeables that, by honesty and intelligent supervision, she rescues her employer from being the victim of. Then, too, her practical, well-trained skill, her scientific education, deserve remuneration."

Thus the employer is to understand that he is to be asked to pay more for a col-

lege-trained girl gardener than he often pays for an experienced, trained gardener. It is clear also from the book that it is not intended that these young ladies should do manual work after a time, but are to supervise men who have had a dozen years' training in gardens, and tell them how the work should be done!

As to the direction of gardeners by students from colleges of the kind described here, just imagine a well-trained man, who has been apprenticed for several years in a good general garden, and afterwards, it may be, has learned fruit culture at Wilton, shrubs at Caerhays, trees at Kew, and has been in a good nursery, in which places he has had an opportunity for the study of design, being lectured by a young lady who has had none of those advantages. Even the most pretentious colleges so called have no trace of design, whereas in a first-rate garden the needs of the place in park, lawns, fruit garden, or orchard compel some thought of design.

The idea that gardening has not been well taught before the coming of the "horticultural college" is a mistaken one. The best schools for gardeners are the country seats of the United Kingdom, in all parts of which there are beautiful and well-cultivated gardens with various means of learning all that can be taught in our islands. It would be well if women would take more share in the garden, as they do on the farm in various countries. In our own land, too, women used to work in gardens in labour suited to them. Now in many districts they will not look at such work. They certainly have their duties to the race and the home to think of first. Besides, there is the fact that, next to work on a sailing ship, gardening out-of-doors on our land is one of the hardest labours for men and wholly unsuited for women.

LAW AND CUSTOM.

A YEW HEDGE.

THE boundary hedge between my garden and a farmer's field is an old Yew hedge. Supposing an animal of the farmer's dies by eating the Yew either by reaching over the fence or from twigs falling into his field, who is responsible? I have given him permission (the farmer) to lop off all the branches on the side of his field, and this he refuses to do.—RECTOR.

[We gather from what you say that the hedge belongs to you as rector of the parish. The subject is one that has been before the High Court on several occasions. In the case of *Crowhurst v. The Amersham Burial Board*, heard in 1878, the defendants had planted on their own land, but so close to the boundary as to project into the adjoining meadow in the occupation of the plaintiff, a Yew-tree, and the plaintiff's horse, whilst feeding in the meadow, ate of the portion of the tree which projected and died in consequence. It was held that they were liable to compensate the plaintiff for the loss of his horse, but in the case of *Ponting v. Noakes*, heard in 1874, it was held that where in such a case the Yew-tree grew wholly within the defendant's boundary he was held not to be liable. Apparently neither of these two cases is exactly on all fours with your case. From what you say we gather that the hedge is a very old one. It does appear, however, from the case of *Smith v. Giddy*, heard in 1904, that a landowner is liable for allowing his trees to overhang his boundary to the damage of his neighbour's crops, and there seems no good reason why this should not equally apply to allowing the boughs of a Yew-tree to overhang to the damage of your neighbour's live-stock. There is a case which was also tried in 1878 (*Firth v.*

Bowling Iron Co.) in which the defendant company's land adjoined the plaintiff's, and was fenced off by a wire rope which it was the business of the defendant company to repair. Through exposure the rope decayed and pieces of it fell on to the Grass on the plaintiff's land, whose cow in grazing swallowed one of the pieces and died in consequence. The defendant company was held liable to the plaintiff for the loss of the cow. Of course, we have not before us the full particulars of your case, but there are two things to be borne in mind which may possibly have some bearing upon its ultimate decision. One is, that if the neighbour's cow got the poisonous Yew by putting its head over the boundary line you could not be held liable, because such reaching over would amount in law to trespass. The other point is that it may be that outside your hedge is a ditch, or what was once a ditch, and that probably belongs to you, because the ditch always belongs to the owner of the hedge inside it, and it may be possible for you to show that it was the duty of the farmer to keep his cow on his own side of the ditch, and that if he had done so she would not have had access to the Yew, which doubtless he knew was growing there; and consequently you would arrive at the same position—namely, that the cow was trespassing. If you like to send us fuller and better particulars we shall be glad to assist you further, if possible.]

Tenant removing plants.—(1) When a tenant plants fruit-trees, Rose bushes, etc., in the garden attached to his house has he any right to remove them when leaving the premises? (2) If he has no right to do so when actually leaving, has he not a right to dispose of what he has planted to his neighbours or otherwise during his tenancy? If he has a right to do this during his tenancy, at what time does the right cease? Is it during the time he is under notice or is it at the expiration of the notice?—HENRY COWIE, *Antrim*.

[When once a tenant has planted fruit-trees, Rose-trees, etc., in his garden he has no right to take them up again at any time, nor is he entitled to dispose of them to his neighbours, nor can he claim any compensation in respect of leaving them behind. The reason for this is that the trees, in law, are part of the freehold, and thus, as soon as they have taken root, they belong to the landlord, who can, if necessary, take action to restrain the tenant from taking them up or otherwise interfering with them.]

Water on excavated land (*Holliday*).—We do not quite understand what it is that is demanded of you. You say they "blame you" for it; but do they suggest that you are to go to any expense in the matter? If so, we can only say that, so far as the facts are revealed in your letter, the demand appears to us to be entirely unreasonable, and we should advise you to see a solicitor if any proceedings are threatened, with a view to defending them. The facts, as we read them, are these: Your house and garden are on a hillside. Above your property is the higher hill-ground from which a good deal of water percolates down into your garden, making the soil there rather too wet. To remedy that you have had some tiles put down in your garden, leading to a "soak-away" at the bottom of it. Below you on the lower part of the hillside is a cricket-field. To make this level they have excavated a portion of the hillside, as it were, close under your garden, and cutting into the part where this "soak-away" process goes on. That is putting your position at its worst. There is no certainty that this "soak-away" is spoiling that corner of their levelled ground. But they are in some way calling you to account from some alleged in-

* "In a College Garden," by Viscountess Wolsley Citizen and Gardener of London. London: John Murray.

fringement of their rights. We cannot see any ground on which they can make a claim against you. We do, however, see a possibility of your garden giving way owing to their excavations, and in that case it is quite certain you would have a right to sue them for damages, as they are removing the support from your land to which you have an undoubted right.—LEX.

ROYAL HORTICULTURAL SOCIETY'S DAFFODIL SHOW.

THE Royal Horticultural Society's Daffodil Show was held on April 18th and April 19th, when a good exhibition was got together. The more important classes contained not a few varieties of merit, and excellent novelties were staged. In the amateur classes many of the flowers were poor, the spectacular side of the exhibition by no means improved by the dingy green baize used at the back of the stands or the never-ending array of mustard-coloured exhibition cards with which the tables were strewn. Surely something better than this would be possible. The one great object lesson of the meeting demonstrated that single blooms, or threes even, contribute but little to an exhibition and afford no clue as to the garden value of the Daffodil. The non-competitive groups did this much better, and the great bank of 800 or so of King Alfred, with others in proportion, from Carter and Co., was something to remember. Following are some particulars of the show:—

OPEN CLASSES.

For a collection of Daffodils, forty-eight varieties, representing the different divisions, Mr. A. M. Wilson, Shovell, Bridgwater, who showed such excellent sorts as Robespierre, Croesus, Iquerna, The Fawn (a fine Leeds), and others, was first. Some under number were exceptionally brilliant and good. Mr. C. Bourne, who was second, had superb White Emperor, Buttercup, Great Warley, King Alfred, Golden Knight, and the richly-coloured Queen of Hearts in a nice lot.

For twelve varieties of Trumpet Daffodils Messrs. Barr and Sons, Covent Garden, W.C., were placed first, having *Famora*, Mrs. G. H. Barr (white Ajax sorts), *Stockwell*, *Justicia*, *Cato*, *Latona*, and *Golden Sovereign* among the yellow selfs. Mr. A. M. Wilson was placed second; we thought, however, his heavier lot of flowers. Not a few were under number—*as, e.g.,* 366 and 413 (bicolor Ajax, a very fine flower). *Diogenes* and *Grenadier* were of special merit.

For twelve varieties *Incomparabilis* forms, Mr. A. M. Wilson, Bridgwater, was easily first, having such as *Croesus*, *Robespierre*, and *Durbar*, all with strikingly brilliant cups. This exhibitor was also first for twelve *Barri* varieties, the whole of his collection being still under number.

In the class for nine varieties *Leedsii*, Rev. J. Jacob was placed first. *White Mere* and *White King* were two of his best varieties, *Sirdar*, *Whitewell*, *Thora*, and *Lowdham Beauty* being others. Mr. A. M. Wilson, Bridgwater, was placed second with, as we thought, a heavier set of flowers. *Venus*, *The Fawn*, *Livonia*, and *Lanceolot* were among the best of those named. The collection, too, was well staged. The latter exhibitor easily led in the class for nine varieties from the *triandrus*, *cvclamineus*, and *Jonquilla* hybrids respectively. The set revealed the strength of the last-named. In the *poeticus* class for nine varieties, Mr. F. Herbert Chapman, Rye, was alone, *Quatrain*, *Marseillaise*, *Biarritz*, and *Bunthorne* being his better sorts.

AMATEURS.

Miss V. Warren, Canterbury, took first prize for twelve varieties fairly representing the different divisions, showing *Pearl of Kent*, *Homespun*, *White Queen*, *Lowdham Beauty*, *Monarch*, *Bennett Poe*, and *Bernardino* among others. Mr. W. B. Cranfield, Enfield Chase, was second, leading, however, in the following class for three varieties, a yellow or lemon trumpet set, and showing *Queen of the West*, *King Alfred*, and *Grand Sire*. Mrs. E. V. Butler, Tewkesbury, was second, showing *Monarch* and *Lord Roberts* well. These two were in like place in the class for three varieties of bicolor trumpets, Mr. Cranfield showing *Weardale Perfection*, *Greave*, and *Florence Pearson*, Mrs. Butler having *Herod* and *Weardale Perfection*. Miss Butler took first place for three varieties bicolor *incomparabilis*, showing *Bedonin*, *Will Scarlet*, and *Whitewell* in good form. Mr. G. Stocks, Doncaster, took first prize for three varieties, three stems of each, *Leedsii*, *Lizzie* and *Zena* being the better things.

OPEN CLASSES (SEEDLING AND NEW DAFFODILS).

Twelve varieties not in commerce, first prize the *Engleheart Cup* and £1, brought a grand lot from Mr. P. D. Williams, Lanarth, St. Kevern, the set embracing *Barri*, giant *Leedsii*, *poeticus*, self and bicolor *Ajax* and *triandrus* hybrids under number being one of the strongest we have seen. Some of the *Barri* and *incomparabilis* forms were of exceptional quality and brilliance. For nine *triandrus* hybrids, Messrs. Barr and Sons,

Covent Garden, took first prize, showing *Alemen*, *Carmela*, *Keziah* (a very fine white), *Lucinda*, and *Silvia*.

For twelve varieties raised by the exhibitor, Mr. A. M. Wilson took the lead with an admirable lot, 402 and 871 among numbered sorts and *Elfin* among named varieties appealing strongly. Messrs. Barr were second, *Model* (a golden *Jonquilla* hybrid after *Buttercup*) and *Golden Empire* (a yellow *Ajax*) being two of the best. For six varieties raised by the exhibitor, Mr. F. Herbert Chapman was first, Mrs. Horace Wright (a glorious *Engleheartii*) captivating all. *Thoroughbred* and *Archangel* were also good things.

For a collection of thirty-six varieties, three stems of each, representing trumpets, *incomparabilis*, *Barri*, *Leedsii*, *triandrus* hybrids, *poeticus*, and doubles, Mr. W. B. Cranfield, Enfield, was first, having *Croesus*, *Venetia*, *White Emperor*, *Sybil Foster* (white *Ajax*), and *Silver Cloud* (*triandrus* hybrid) all very good. Mrs. Ridley, who was second, had very fine *Croesus* and *Lady Margaret Boscawen* in her set. Four collections were staged in this class.

NON-COMPETITIVE EXHIBITS.

Messrs. Carter and Co.'s great bank of Daffodils, with its hundreds of the rich-golden *King Alfred*, *Lady Margaret Boscawen*, *Mme. Gamp*, *Lucifer*, *Dazzler*, and others, was one of the features of the meeting. Messrs. Dobbie and Co., adapting their *Sweet Pea* style of exhibiting to the Daffodil, showed many of the most popular sorts in imposing stands. It was a welcome change to the eternal ones or two rigidly fixed in an exhibition jar. *Seagull*, *Firebrand*, *Duke of Bedford*, *Sir Watkin*, *Flambeau*, *King Alfred* were all so shown and looked admirable. Messrs. Barr and Sons had a rare novelty in *Pink Beauty* with coloured trumpet. *Golden Monarch*, *Golden Apricot*, *Golden Comet* (a *Buttercup* or *Jonquilla* form), *Nannie Nunn* (brilliant crown), and *Coralind* (a *Leedsii* with apricot-coloured crown) were some of the good ones. Messrs. R. Sydenham, Limited, Birmingham, had a lovely lot of *King Alfred* and a big display of *Lady Margaret Boscawen* among many. Messrs. R. H. Bath, Limited, showed a big batch of *Flame* (an *incomparabilis* of merit), *Croesus*, *Crystal Queen* (giant *Leedsii*), the new *White Pennant*, and Mrs. R. Sydenham. Messrs. J. R. Pearson, Lowdham, showed *Empire* (a giant bicolor *Leedsii*) well, *White King*, and *Potentate* (yellow *Ajax*) among others. *Buttercup*, *White Emperor*, *Pixie*, and *King Harold* were some of the best in Mr. C. Bourne's collection.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Plants for exposed rock garden (K. B.).—*Achillea tomentosa*, *Achillea umbellata*, *Ajuga reptans purpurea*, *Alyssum saxatile*, *Arabis alba*, *Arenaria montana*, *Cerastium tomentosum*, *Cotoneaster humifusa*, *Cotoneaster thymifolia*, *Cytisus Ardoini*, *Draba aizoides*, *Genista sagittalis*, *Genista tinctoria*, *Linaria cymbalaria*, *Lotus corniculatus*, *Muehlenbeckia vernalis*, *Oxalis corniculata*, *Pyrrhtrum Tchihatchewi*, *Rosmarinus prostratus*, *Saxifraga umbrosa*, *Sedum lydium*, *Sedum spurium*, *Silene alpestris*, *Thymus Serpyllum* (in variety), *Veronica prostrata*, and *Veronica repens*.

Unhealthy Gardenias (Gardenia).—The main cause of the deformed flower buds and unhealthy appearance of the plants in question is, no doubt, largely, if not entirely, due to a very bad attack of mealy-bug. The specimen twig and bud sent were literally swarming with it; we never remember seeing a worse case. If the plants are all like the sample sent, the best way would be to destroy them at once by burning them, thoroughly cleansing the house by scrubbing woodwork, whitewashing walls, painting, etc.; and then replacing the plants by a clean and healthy stock. To keep *Gardenias* clean great care is required. They should be freely and forcibly syringed every day with clean water, and occasionally with a mixture of paraffin-oil and water; a wineglassful stirred into 3 gallons of water is a safe mixture. This should be kept continually agitated whilst it is being used, and, if the sun comes out after it is applied, the glass should be shaded, or the foliage is apt to become scalded.

FRUIT.

Peaches dropping (Disappointed).—The failure arises from one of three causes. Either the wood is not properly ripened in the autumn, or the soil in the border is allowed to get too dry during the autumn and winter. But from the tone of your inquiry we are disposed to think that the soil in the border is too deep and too rich. In such a case the wood would not ripen satisfactorily. Many people err in making *Peach* borders under glass too deep, and the soil too rich, which is a great mistake. Good loam is all that *Peaches* require to grow in under glass. What stimulants they want can be given in the form of liquid-manure or surface dressing.

VEGETABLES.

Beet and recently manured ground (A. R.).—Ground recently manured is not suitable for root crops such as *Beet*, *Parsnips*, or *Carrots*,

as the fresh manure causes the roots to fork badly, and renders them almost valueless. We would certainly advise sowing in the plot that was not manured.

Cutting seed Potatoes (White Rose).—The cutting of seed Potatoes before planting must depend upon the size of the tubers. As a rule, there is no better seed, whether of round or kidney shape, than sets weighing six or eight to the pound, provided they have been well kept and not permitted to grow out in the winter through bad storing. If the sets be more than 4 oz. each, then they may be cut through the middle, and larger tubers may be cut three or four times. The great object in cutting should be to make the most of the tuber by leaving at least one strong eye or shoot to each set.

MISCELLANEOUS.

Moles (K. B.).—If you can find the main runs, procure some of Calvert's No. 5 carbolic acid. It is very powerful, and should be handled with great care. Place some in a small bottle in each run. The smell is very penetrating, and will probably drive them clean away.

Shading greenhouse (Shade).—The use of various washes for shading is good for houses requiring permanent shading, but there are many objections to the use of whitening, etc., in the case of plants requiring all the light that can possibly be obtained. The best system of shading is to use roller blinds. The blind is fixed to a lath outside the house, as near to the top of the roof as possible. The other side of the blind is fixed to a roller with tinned tacks. The roller should project a little at one end, and on the projecting end be fixed a grooved wheel which will enable the roller to be pulled up or let down in an instant.

SHORT REPLIES.

K.—It is very difficult to say, as you give us no idea as to the garden you refer to. If very shaded and surrounded by buildings the only plants likely to do any good are hardy Ferns.—*Porch.*—For such a position as you refer to you will find the *Lapageria* very suitable.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*Dr. R. Thorpe.*—*Berberis Darwini*, so far as we can make out from the meagre specimen you send us.—*J. Lynn.*—Malformed flowers of *Cobaea scandens*.

CATALOGUES RECEIVED.

J. STANFORTH AND CO., LTD., 12, Charterhouse Buildings, Goswell-road, London, E.C.—“*Stanforth Tools*.”

Trial of Stocks at Wisley.—A trial of biennial and winter-flowering Stocks will take place at the Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey, during next winter and spring. One packet of each variety to be tried should reach the Director, from whom the necessary entry forms may be obtained, not later than Monday, May 9th.

OBITUARY.

LIEUTENANT ERIC G. SUTTON.

It is with deep regret that we hear of the death, at the age of twenty-one, of Lieutenant Eric G. Sutton, who was killed on April 8th. He was the second son of Mr. Leonard Sutton, of Reading, and, as our readers will remember, was given the Military Cross for his bravery in connection with a mine explosion in September of last year. He was educated at Rugby, and after visiting France and America he, on the outbreak of the war, returned home and was gazetted to the Royal Sussex Regiment in September, 1914, gaining his lieutenancy in the following June.

M. PIERRE GERMAIN.

WE regret to say that a young French horticulturist has lately died from tetanus following a wound received while at work in a Welsh garden. Tetanus is a terrible disease, to which gardeners and others who work in the soil are perhaps the most liable, and which, we believe, has been very prevalent among our men in Flanders. We believe there is a serum which, if applied in time, cures the disease, but in this case it was not applied. The microbe of tetanus certainly infests certain areas of cultivated land, and therefore all who work in such areas should, in the case of the slightest cuts, thoroughly wash and protect the wound in the first instance.

TREES AND STORMS.

LATELY I heard a heavy gale blowing, and thought of some of my friends who have big Cedars and other coniferous trees standing alone all dressed to the ground in crinoline fashion. The common teaching of the books is quite wrong about the necessity for planting this precious Conifer by itself. It is the surest way to have trees knocked over in a gale. In the west of England I have been grieved to see the numbers of Cedars of Lebanon laid low. It is rarely one sees a Cedar showing its stem, and very rarely Cedars grouped. The true way is to plant the trees well together and let them shelter and protect each other. It is best for their health and for their good effect.

Anyone who looks at Pines in the well-planted or the natural wood will often find them growing very close together, and, even so, growing very large, as one may see in the Silver Fir woods of Auvergne, tall Pines of good measurement growing within a yard of each other. And this is true not only of Pines, as I remember at Angers visiting the botanic garden there with Professor Sargent and seeing very noble Planes growing within a few feet of each other.

It is a common mistake to suppose that such trees want immense space to grow well in. In one of the most important books on Conifers in our language we are told to leave as much space of ground round each tree to grow in as is the height of the tree. As many trees of the Pine tribe are 80 feet to 100 feet or more high that is an absurd idea. Trees in forests or otherwise need no such amount of space; in fact, it is against them, as it enables the Grass to rob their roots. One of the good results of planting the trees close together is that they keep away Grass and weeds. Three or four kinds of Pines well grouped may give a better effect than a hundred kinds put about in a weak, dotty way.

I have this from a friend in the Thames Valley:—

Elms, Cedars, and Firs were the trees which went down in the recent storms in this district. There are many Planes in the neighbourhood, but I have not seen or heard of one that suffered. A great number of Chestnuts fell in Bushey Park, and most of the Elms in King Edward VII. Avenue, Windsor. Cedars grow singly about here, and when not sheltered by a house fell. Many Oaks had big branches wrenched off but none were uprooted.

The Marquess of Huntly sent an inter-

esting note to *The Times*, which appeared on p. 193, on the trees which have best withstood the great gales at Orton. Nothing is said of soils or conditions, or whether the trees were grouped or set out in the single way usual in pinetums. One precious fact comes out clearly, the resisting power of the "Big" Tree (*Sequoia*) in our northern land. I remember Professor Jepson, who knows the Californian trees and tree land by heart, told me that tree was harder than the Redwood, and the notes from Orton further prove its fitness for our islands. Unfortunately, this great tree is often planted alone, like a lighthouse, and gets no advantage of a shelter and the other gains that grouped or massed trees enjoy. I had so often seen the Big Tree by itself in the middle of a field or lawn with all the winds of heaven dancing about it to its injury that I got an idea that it was a tender and worthless tree, and until my friend Professor Jepson told me its character in California I ceased to plant it, and have lost a quarter of a century by so doing. In fact, it promises to be a very important tree in our country, and should be planted in a sheltered place in woods to begin with.

The recent gales were certainly exceptional in their destruction, but we may again point out that severe storms of this kind are certain to recur periodically, and some precautions against their ravages should be taken in time. Without doubt there are winds that nothing can resist, not even the closest planted wood, but such winds are of rare occurrence in our southern country; all the greater reason, therefore, for taking precautions against them. This is best done in the form of what are called in other countries shelter belts. The best way to use them is to put them against the coldest and most unpleasant winds. We mean, of course, in places where there is room for planting, such as farms, orchards, parks, and gardens.

A great deal of the planting done in country places is in the form of very poor, skimpy fringes round the place which are of no use for shelter or anything else. Much the best way is to find out the dangerous points and plant well against the prevailing or dangerous winds. In our country we have some of the best evergreens for this purpose in the Hollies, the Yews, and the excellent evergreen Oak, which all round our coast-land in England and Ireland is the best wind-break that can be found. Where the wood is thick, as it should be, then the Austrian and Corsican Pines come in very well. The

dot-planting and little rings about a park are no good either for effect or for any comfort that woodland gives. It is useless putting the noble trees of the Pine tribe about like electric standards, it only invites disaster, as we see in the case of the Cedar, and it also destroys all effect of form, because if the tree only forms a round lump on the ground, no matter how high it may be, one gets no idea of its dignity or grace. Where the Cedars grow on the mountains of North Africa or Asia they are kept together, and one can see the beauty and dignity of their stems, and so it ought to be in our planting. We hear that in one town in Herts over 5,000 fine trees were blown down. It is well, therefore, to consider the trees that are apt to give way the first and to avoid planting them. It is sheer folly to plant the Field Elm, or any other Elm, anywhere almost.

W.

NOTES OF THE WEEK.

Omphalodes cornifolia.—Withered a bit on the way, but clearly a welcome member of this interesting genus of hardy plants. The new kinds are charming things. From Sir Frank Crisp.

Haller's Windflower (*Anemone Halleri*).—This, from Sir Frank Crisp, reminds one of the Pasque Flower, and is clearly a good thing. The point is to grow it well and increase it freely. It lives with me on a dry bank, but has not bloomed freely. *A. Pulsatilla* is free as a garden edging and gives a lovely effect.—W.

Crocus: A long-blooming season.—Seldom do I remember Crocuses continuing in bloom so long as this season. In my garden the first flowers were open on January 9th. These were in a sunny spot at the side of a gravel path. Now, in the last few days of March, some yellows are glorious in a north aspect, while on a bank facing north, in the Grass, they are at their best. I grow them in big groups of one colour, and in this way they are far more effective. Both yellow and light colours are more striking than blues.—W., Surrey.

Anemone apennina in a sunk garden.—There is a delightful sunk garden in the gardens of Mr. James Brown at Knockbrix, Borge, Kirkcudbright, and in the month of April a large group of a good variety of *Anemone apennina* was remarkably fine, the blue flowers charming against the grey walls of the sunk garden with their adornment of trailing and climbing plants. The Apennine Windflower is one of the best of the spring

Anemones, its starry flowers being quite distinct from those of the *memorosa* class, of which *A. n. Robinsoniana* is yet the finest of the blue varieties.—S. A.

Collomia grandiflora.—This pretty little annual, seeds of which were sent to me from British Columbia, sows itself on my dry banks, and is welcome in April. It is distinct from the others which are commonly grown, though not so large in flower as the name might lead one to expect.—W.

A guide to Kew Gardens.—Under the authority of the Board of Agriculture, and upon the recommendation of the Directors of the Royal Gardens, Kew, ladies and gentlemen interested in horticulture will be conducted over Kew Gardens on Mondays, Wednesdays, and Thursdays in each week by Mr. John Weathers, who will deal with the most seasonable and interesting features. Parties will meet at the principal entrance on Kew Green at 3 p.m. on the days mentioned, and a fee of 2s. 6d. will be charged to each person to prevent overcrowding and inconvenience. Further particulars may be obtained from Mr. J. Weathers, Park View, Isleworth.

Rhododendron racemosum.—This dwarf Rhododendron, from Western China, is a grand subject for the rock garden. It comes into bloom towards the end of March or beginning of April. Its flowers in the half-opened state are of a deep rose-pink shade, but when fully expanded, and the inside of the corolla is shown, they assume a pale pink shade. As its name indicates, the flowers are in the form of racemes or corymbs. It is a very free bloomer and attains a height of from 1½ feet to 2 feet.—ALBION.

[A pure white form of this Rhododendron was shown at the meeting of the Royal Horticultural Society on May 2.]

Narcissi in Kirkcudbrightshire.—Narcissi of all kinds seem to be flowering well in the south-west of Scotland this year, and, although late, they have been very good. A glorious display has been made in Mr. James Brown's garden at Knockbrex, which is situated close to the Solway in the south-west of Kirkcudbright. In other parts of the same district these flowers also do exceedingly well. Along with the older *Ajax* and *incomparabilis* varieties there were big groups of such as *Mme. de Graaf*, *King Alfred*, and many more of the newer kinds. A particularly beautiful effect was produced by great numbers at the margin of one of the lakes, where the blooms were reflected in the lake with the most enchanting results.—S. A.

Kerria japonica.—Although this plant is best known by its double-flowered form, the type is a very beautiful shrub. Really a native of China, it appears to have been early introduced into Japan and to have become naturalised there, hence the specific name. In 1804 the double-flowered form was introduced to the British Isles, where, in the absence of the type, it was called *Corechorus japonicus*, a name it retained for thirty years until on the introduction of the single-flowered shrub it was found to have nothing to do with *Corechorus*, and was named in honour of the collector, William Kerr, who introduced the double variety. The type forms a rather dense, but shapely, bush, 3 feet or 4 feet high, with arching branches, which during April and May bear freely rich-yellow flowers, each about 1½ inch across. The double-flowered variety, on the other hand, is of stiff, erect habit, sometimes 8 feet or 10 feet high, with stout branches, bearing flowers each up to 2 inches across, the blooms on dif-

ferent plants varying a good deal in size. In the North of England the double-flowered plant is often grown against walls.—D.

Gentiana excisa.—This fine Gentian is now in flower on a retaining wall between sandstone blocks. Not being quite sure of its name, I sent it to Mons. Corveon, who says it is the true name of a form of *G. acaulis*, of which there are, according to the botanists of the day, four types—*G. alpina*, *G. angustifolia*, *G. Clusii*, and *G. kochiana*. These should be easy to grow in cool soils, though we never see them flower so well as in Ireland or Scotland. A sandstone block over the plants seems to suit them.—W.

Osmanthus Delavayi.—This new Osmanthus is evergreen, flowers freely in early spring, and the blooms are fragrant. There is, however, a doubt as to its hardiness. It can, however, be grown in the south and south-west counties, and succeeds in the open about London. A native of Yunnan, China, it was introduced to France in 1890, but has only been grown in the British Isles for a few years. In China it sometimes grows 6 feet high. The white flowers appear in small clusters from terminal and side buds during April and early May. It succeeds in loamy soil, that which is light and well drained being most suitable, and it can be increased by cuttings of half-ripe shoots placed in a close frame in summer. In cold districts it deserves a wall.—W. K.

Aubrietias on walls.—Nowhere does the *Aubrietia* look better than on a wall, where its trailing habit and masses of flowers create a fine display in the spring. Even in places where the *Aubrietia* is a failure, or, at least, a disappointment, on the level or on rockwork, it often succeeds admirably on a wall. There are places where the *Aubrietias* are practically destroyed in wet winters if on the level. The *Aubrietia* never is more beautiful than when hanging down the face of a wall. At Pollok, Sir John Stirling Maxwell's garden, close to Glasgow, the *Aubrietias* are a brilliant feature on the wall of the terrace. At Knockbrex they are utilised on a terrace wall overlooking a small moat, and there they are exquisite, harmonising well with a fine blue *Myosotis* at the base. Dr. Mules and other good named varieties are on the wall and are very beautiful against the grey stone.—S. A.

Thunbergia Gibsoni.—The notes on indoor plants from W. McGuffog are always of interest to me, as he frequently deals with subjects that are now very rarely seen in gardens. In his article on *Thunbergias* (page 222) he makes no mention of *T. Gibsoni*, so I conclude it has not come under his notice. This is not to be wondered at, for, though a very desirable species, its light seems to be hid under a bushel. It is a native of Central Africa, whence seed was sent a few years ago, and a specimen resulting therefrom was shown at a spring meeting of the Royal Horticultural Society in 1913, when it received an Award of Merit. Its nearest affinity is with *Thunbergia alata*, from which it differs, however, in several well-marked features. Instead of being an annual, as in the case of *T. alata*, this newer kind is of perennial duration, and can be readily struck from cuttings as well as raised from seeds. Allowed to assume their natural character, the shoots lie flat on the ground and extend for a considerable distance. The flowers, borne upright on firm stems, protrude from a large, inflated, hairy calyx, in colour green, striped with purple. The blossoms themselves are larger than those of *T. alata*, and of an intense, brilliant, orange colour. Good examples of this *Thunbergia* were ex-

hibited at the Chelsea Show two years ago, but I have looked in vain since then for any announcement of it having been distributed to the public.—K. R. W.

The double-flowered Gorse forms a more compact bush and is tidier during the summer, when the seed-pods of the single-flowered plant render it rather unsightly. The double-flowered Gorse is excellent for clothing dry banks of poor, stony soil, where few things would succeed. A good object lesson regarding its use for such a purpose is to be seen at Kew, where in several places what were bare, unsightly banks a few years ago are now most attractive. The double-flowered Gorse is at its best during April and May, and for nearly two months it is a mass of gold. The provision of good soil or manure is a mistake, for it only promotes rank growth, which does not flower so freely as that of a stunted character. Increase is by cuttings, each 3 inches to 4 inches long, inserted in a cold frame during July or August. Roots ought to be formed by the following April, when the young plants should be potted and kept in pots until they can be placed in permanent places.—W. K.

Grevillea rosmarinifolia.—This *Grevillea*, concerning which "Byfleet" inquires (page 221), cannot be the same as he grew some years ago, as his plant only attained the height of 1 foot, whereas *G. rosmarinifolia* will grow 6 feet or 7 feet high and as much through. It is one of the hardiest members of the genus, and though it will only survive mild winters around London, it is at home in sheltered places along the south coast and in Devon and Cornwall. The leaves, which are closely set on the branches, are each from 1 inch to 2 inches long, and very suggestive of those of the Rosemary. The rosy-red flowers are borne in dense terminal racemes, the long, prominent style being bright red in colour. A second species, quite as hardy as *G. rosmarinifolia*, is *G. sulphurea*, which forms a bush of much the same height as the preceding. The leaves of this are needle-like, and the flowers of a pale yellow colour. They are freely borne during the months of May and June. The *Grevillea angustifolia* alluded to was, I understand, quite a different plant from either of these.—W. T.

Rhododendron rhombicum.—This is one of the earliest of the deciduous species to bloom, for it is usually at its best well before the end of April. A native of Japan, it is known as a spreading bush 3 feet or 4 feet high, with curious diamond-shaped leaves, which are usually very pretty when they first develop, the margin being of a bright reddish-brown and the centre green. The flowers appear in advance of the leaves and are usually produced one or two together from the joints of the shoots. Each one is upwards of 1½ inches across and of a delicate shade of rosy-purple. It is doubly welcome, as it is often in full flower by the middle of April. Its only drawback is that the flowers are often injured by late frosts, therefore it should be planted where it will receive some protection from cold north and east winds, and be shaded from early morning sun. In other respects it may be given similar conditions to other Rhododendrons or Azaleas, sweet, moist soil, moderately free from lime, and a good surface dressing of decayed leaves.—D.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

TREES AND SHRUBS.

ABUTILON VITIFOLIUM.

This beautiful flowering shrub, a native of Chili, is quite hardy in many parts of Ireland and the warmer districts of England. It can also be successfully grown and flowered in less favoured districts provided it is afforded shelter from cold winds and given a warm and well-drained soil. The plant here figured is 8 feet high and covered with foliage to the ground level. It is growing on a sheltered bank with a background of Yews. The flowers of this Abutilon are pale lavender in colour, and the leaves resemble in shape those of the Vine. Although often not a very long-lived plant,

are borne in each leaf-axil. As in the case of the spring flowering section of the genus, it requires little pruning. An occasional thinning out of the older branches relieves the younger ones and admits light and air to the centre of the bushes, which are very necessary for the proper ripening of the wood. The cultivation of this class of Spiraea offers no difficulties, for it thrives in any good garden soil. Seeds are produced freely, and they form an easy means of propagation, whilst quite as good results may be obtained from cuttings of the semi-ripe wood put into pots of sandy soil, in a close frame, during July and August.

The Fothergillas.—Only two species of Fothergilla are grown to any extent in our gardens, but both are interesting shrubs.

advance of the leaves. The conspicuous part of the flowers is the mass of white, thread-like stamens, the petals being absent. The second species is *F. major*, a superior shrub in every way. Of vigorous, erect habit, it forms a bush up to 6 feet or more high, spreading by means of shoots, which spring from the base. The terminal flower-heads are set in autumn, but they do not develop until late April or early May, just before the leaves, when good-sized, erect heads of white, fragrant flowers are borne. In this case, also, the stamens are the conspicuous part of the flower. The leaves in autumn turn to a bright shade of yellow before they fall. The leaves of the other species turn red in autumn. *F. montana* is very like *F. major*, and is occasionally seen in cultivation.—D.

Pyrus folgneri.—This is one of the most beautiful of the several species of *Pyrus* introduced from China within recent years, and is likely to become very popular. Growing to a height of about 30 feet, it forms long, slender branchlets which assume a pendent habit. The leaves are long and narrow, dark green above and silvery beneath, a very pretty effect being produced by the combination when the branches are stirred by the wind. The white flowers are borne in dense heads up to 4 inches across, and they are succeeded by oval-shaped red fruit. As a specimen tree on a lawn it is very suitable. Originally introduced by Mr. E. H. Wilson when collecting for Messrs. Veitch, its first appearance in this country dates from 1901. It was known for some time as *Micromeles folgneri*, a name sometimes given to a few species of *Pyrus* which possess minute botanical differences from other *Pyruses*, but the name of *Pyrus* has been retained by Mr. Bean in his book on "Trees and Shrubs Hardy in the British Isles."—D.

Abutilon vitifolium.

if planted in suitable positions it may be depended on to grow and blossom freely for a number of years, while it can be readily replaced by raising young plants from seed, which in some districts ripens freely. It can also be propagated from cuttings inserted in pots of sandy soil and placed in a close and slightly warm propagating frame. F. W. G.

Lilford Gardens, Northamptonshire.

NOTES AND REPLIES.

Spiraea Henryi.—This *Spiraea*, introduced some few years ago from China, belongs to the canescens group, and blooms during the latter part of June and early July. Of robust habit, it grows 4 feet to 5 feet high, with long, semi-pendent shoots, from which the corymbs of small white flowers

They belong to the same natural order as the Witch Hazels, and, like those shrubs, have very quaint flowers. The genus is native of eastern N. America, where several kinds grow in moist, light soil. Here they are found to succeed best in light loam to which peat or leaf-mould has been added. They like sun, but should not be planted where they are likely to suffer from dryness in the event of a period of drought. They can be propagated by layers or by cuttings. Seeds sometimes ripen, and they may be used as a means of increase, although it does not appear to be possible to procure them regularly. *F. Gardeni*, sometimes called *F. alnifolia*, is the better known shrub. It grows 2 feet or so high, bears oval, Alder-like leaves, and produces terminal heads of white flowers in May a little in

VEGETABLES.

POTATOES.

RECENT notes on Potatoes confirm me in a view which I have always held—that locality has much to do with the success or the reverse of certain varieties. Two varieties mentioned in the issue of April 8th may be taken as instances. These are Langworthy and King Edward VII. Langworthy is here an utter failure, and after repeated trials has been discarded. On the other hand, King Edward VII. yearly gives most excellent returns, the only fault—if fault it can be styled—being that the tubers are rather too large. These Potatoes, when Langworthy was grown, were planted on the same quarter and given precisely the same treatment in respect of manure and attention. Here, too, British Queen practically fails, while Up-to-Date is, as a cropper, equal to King Edward, though inferior in quality. The note upon "greening" seed tubers in a recent issue and the remarks over the initial "T" were also highly interesting. Greening immature seed was at one time largely followed in Scottish gardens, and it always gave good results. The practice has never really fallen into disuse among cottagers in this district, many of whom still select their seed-tubers as lifting goes on from day to day, and lay them upon the garden walk, fully exposed to the sun, until they are thoroughly greened. Disease, they say, is not so liable to attack crops grown from "greened" seed-tubers; and while they cannot explain their reasons for this, yet it is evident by inspecting their crops that this is so. Possibly the increased use of chemical manures may have something to do with the proneness of the Potato, nowadays, to disease, and as the

cottagers referred to use little or no artificial their freedom from disease may be in some measure attributable to this, and generally to under rather than over-manuring. In addition to the old variety, Dalmahoy, mentioned by "T.," several other good old sorts occur to me. For example, Regent, Champion, Skerry Blue, American Rose, followed by such kinds as Schoolmaster, Magnum Bonum, White Elephant, and others. About twenty years ago a variety known as Adirondack—of American origin—was popular in this district. As is the case in most things, the old sorts are ousted by novelties, and varieties of Potatoes nowadays appear to increase in numbers rather too rapidly than there is any occasion for. In Kirkcudbrightshire during 1915-16, crops were above the average, and the prices were very moderate. W. MCGUFFOG.

Balmæ, Kirkcudbright.

CUCUMBERS WITHOUT FIRE-HEAT.

In frames on hot-beds early in the summer, and in frames on cool-beds during mid-summer, good crops of Cucumbers are grown. Many amateurs possess small lean-to and span-roofed houses, and in these grand crops of Cucumbers may be grown during the summer without the aid of heat from hot-beds or pipes. A successful amateur cultivator in Lancashire used to cut turves—most of them from the roadsides—and form a bed with a firm front 18 inches deep and 2 feet wide at the base, tapering to 18 inches at the top. The turves forming the interior of the bed were chopped into very small pieces and some well-rotted manure and leaf-soil mixed with them. The Cucumber plants were raised in a box covered with glass and planted out when the first rough leaf was about the size of a penny. A space of 30 inches was allowed between each plant, the haulm being trained to wires about 18 inches from the roof-glass. Each young plant was shaded from bright sunshine with paper till well established; afterwards the glass was lightly shaded, the plants stopped regularly beyond each joint on side shoots after the main stem had been stopped when three-parts up the roof. Very little ventilation was given, sun-heat being husbanded. Light and frequent surface mulches, judicious watering and feeding with liquid manure, resulted in the production of enormous crops. G. G. B.

NOTES AND REPLIES.

Carrots.—The sowing of the main crop will be made as soon as the weather and the state of the ground permit. It is most important for this crop to choose a time when the ground is dry. The ground chosen should have been heavily manured the year before and prepared by deep digging without manure last autumn or winter. Sow the seeds in drills 1 foot to 15 inches apart and 1½ inches in depth, and after covering the seed and before raking the land give a good dressing of soot. Carrots growing in frames need careful attention, admitting plenty of air in fine weather and affording water as often as necessary.

Brussels Sprouts.—This is one of the most important autumn and winter crops, and the time has arrived when good breadths raised from seed sown under glass will be got out. The most suitable quarter in the kitchen garden for the main crop is that which is of good depth, has been heavily manured and deeply trenched, and has not carried a crop of the Brassica tribe for two years. If the land be not firm it must be made so by treading, as a loose soil invariably produces soft Sprouts. The plants should be allowed a distance of from 2 feet to 2½ feet apart each way, according to the nature of the soil or the size to which the varieties grow. On strong land the wider distance is advisable for all. Lift the plants carefully and do not expose the roots too long to the air.

Spinach Beet.—With a view to obviate frequent sowings of the summer variety to maintain the supply, Spinach Beet will be largely grown this season. A good sowing will now be made, and when the plants are large enough the thinnings will be transplanted into good ground. The quality and flavour of the

tops are, of course, not to be compared with those of true Spinach when cooked, but it has the good point of yielding a plentiful supply over a long period without bolting to seed, which summer Spinach does all too quickly when warm weather sets in.

Tomatoes in pots.—The plants having now made good progress—grown up till now three plants in an 8-inch pot—they have been placed in their fruiting-pots. The soil used is by no means rich, and in the meantime the pots were not much more than half filled. This practice checks any danger of damage arising from a too free use of water, and as growth continues, top-dressings can be given as required. For top-dressing a little good chemical manure is of distinct value to Tomatoes in pots.

GARDEN FOOD.

SALADS.

On the Continent anything in the way of cold, left-over vegetables is turned into salads, while in America many vegetables which we never eat raw are used for the same purpose. There is much to be said in favour of using up cold boiled vegetables in this manner. It is very economical, for it turns odds and ends, too small to be employed in any other way, into tasty and appetising dishes. Cold Potatoes can be sliced, mixed with Lettuce, Endive, or any other green salad that may be in season, a simple dressing poured over, and eaten with either cold or hot meat. Chopped Carrots and Potatoes, covered with a good salad dressing, and sprinkled rather thickly with chopped Parsley, are very good. French and Broad Beans also make another nice salad, but I have never seen this combination eaten in England. Green Peas and Potatoes or green Peas and shredded Lettuce are two more combinations that are great favourites in Belgium.

At one "hotel" (it was really a café) where I spent some months an extra quantity of vegetables was cooked for the mid-day meal, and the remains were always mixed together and served with the evening dinner, being eaten with either cold or hot meat, fish, or omelettes. In fact the vegetables at the evening meal were always turned into a salad. Apparently there was no rule for the mixing, any cold vegetable being dished up again. The dressing was made by mixing oil and vinegar, a very little salt, sugar, and mustard. This dressing took some time to make, as the vinegar and oil had to be added alternately, a little at a time, until all had been mixed. Then it was set aside in a cool place for two hours, the dressing being added to the vegetables at the last minute before serving. I prefer Lemon-juice to vinegar in this dressing as the flavour is more delicate.

A delicious fruit salad is made in France by slicing an equal quantity of Oranges and Apples. These slices must be perfect rounds, cut across the fruit. Both fruits are peeled before slicing. Arrange the slices in a deep glass dish, placing an Orange and Apple slice alternately, each slightly overlapping the other, around and around until the dish is almost full. Sprinkle a little caster sugar over each slice, and a fair amount over the whole. Set the salad aside in a cool place for two hours, and serve very cold. A nice American salad for serving hot is made of Oranges. Peel and slice several sweet Oranges, sprinkle with a little sugar and a liberal pinch of cayenne pepper. Add the juice of two Lemons and cover the whole with a plate. Stand in the oven until very hot and send to table with a mock "wild duck" roast made with brown Lentils flavoured with fried Onions and chopped Sage formed into a roll and baked. Another American salad is made from the heart of a small spring Cabbage. It is very good, but as a rule

English housewives are afraid to try it, disliking the idea of eating raw vegetables. Remove all the green outer leaves from a very fresh, firm-hearted Cabbage. Cut out the stalk, and slice the white heart very finely. Wash well and toss in a cloth or basket to get rid of the water. Lay the Cabbage shreds very lightly in a salad bowl. If the flavour is liked add a little chopped Shallot. Cover with a good mayonnaise dressing and garnish with chopped Beetroot. Cauliflower is also delicious eaten as a salad. The flower is broken into tiny pieces, mixed with shredded Lettuce, and an equal quantity of chopped Celery. Either mayonnaise or ordinary salad dressing may be used with this salad. Chopped Cauliflower can be employed instead of Nuts in making a salad in which Nuts form one of the ingredients. No one will be able to detect the difference after the dressing has been added. All raw vegetables, such as Cabbage and Cauliflower, should be perfectly fresh.

H. THOBURN-CLARKE.

Apple Claygate Pearmain.—Something I said in a note about this is a little misleading. I meant to say that, generally, another Apple is sold for it, but I presume there can be no real trouble in getting the true variety.—W.

Wholemeal bread (unfermented).—Put 2 pints cold water into mixing-bowl, stir in a little at a time sufficient wholemeal flour to make a moderately stiff dough. Mould up into six to twelve small loaves, well knead and bake in a quick oven for about forty-five minutes.

Apple Carter's Pearmain.—Mr. Will Taylor, Hampton, writes of this, and sends one specimen, which, though out of condition, is a very interesting Apple and good in flavour. I should like to taste it when it is in good condition. We have so many Apples that it is a mistake to grow any unless proved good. This seems a good Apple, a neglected old sort probably, and well worthy of attention.—W.

Broccoli.—I get the best sorts of Broccoli, well grown and well cooked, but the flavour is bitter, and acid, and unpleasant. This cannot be necessary. We know, in fact, from the large purple Broccoli and the sprouting sort, which are sold in the London market, that the Cauliflower race need not have any such flavour, and it should be possible to raise a race of plants entirely free from it. It is work worthy of our seedsmen and hybridists.—W.

Beans and Lentils.—Among the most precious sources of garden food are the pulses, as they are so well grown on the Continent and also here. Well cooked, they are a very important part of garden food, and a great help to the food reformer. Like everything else, they have gone up in price, so much so as to be almost prohibitive. Messrs. Barr and Sons, who had the good idea of introducing these as a source of food, write as follows as regards the change in price:—

"Until the war broke out we offered these eating seeds by measure. The cost of them, however, has so increased that we were unable any longer to sell at the same rate, and we thought it better, therefore, to sell in packets, each packet being sufficient for a fair-sized dish. When normal conditions again prevail we shall offer in a different manner. Seed of Peas and Beans for food cannot now be imported, the French Government and other European Governments having prohibited the export. We have, therefore, had to pay full seed prices."

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

GARDEN PLANS: MOTHER EARTH OR THE DRAWING-BOARD.

Mr. Robert Marnock found "plans were essential to his work," and, "however carefully thought out the plan, he found it necessary to modify and improve it on the ground whenever he could." Of course, he did. I do not believe any really great work in architecture, painting, music, literature, or gardening was

"backgrounds, near groups, views near or distant, gradations of earth, and nature of soil and vegetation of the place," and then make his plan on paper, not because the drawing of the plan will compete with the work on the ground, but will assist it in determining areas, calculating gradients, estimating quantities where excavations have to be made, and determining the most economical method of carrying out the work. Finally, it will give to subordinate workmen clear and definite instructions to which they can refer during the progress of the work. This latter point is of the utmost value, especially

able to a similar site, but it must only be the idea and not the plan that is adopted. Nothing is more fatal to good garden design than the endeavour to force into unsuitable situations a treatment because it has proved eminently successful elsewhere. Neither have I any sympathy with the young man in a builder's or architect's office who prepares garden plans and uses his trees, shrubs, and plants on the same principle he arranges for the disposal of drain-pipes and bricks; but here, again, it is the man, not the plan, that fails. The "park-like country round London and in the home counties spoilt by planting trees

Lower lake, Gravetye; summer. An old "hammer" pond.

ever completed according to the original intentions of its creator, so far as the smaller details were concerned, and no one realises more fully than I do that the best plan ever produced can be improved on application to the site. It is just as true that the best garden scheme ever imagined can be improved by giving it the utmost consideration by preparing plans. It is not the plan, but the man who prepares it, makes the garden, or anything else, what it is.

"W. R." says the main question is paper or earth, and he would be a fool indeed who tried to make paper take the place of work on the ground. A wise man would study the site, and fully consider

when the work covers large areas and it is necessary to carry out various portions of a connected scheme at the same time, but with different sets of workmen.

"W. R." says he has never used drawings in any of his work, but this does not prove that drawings are useless, but that he possesses a sense of composition, an instinct for what is good, and the requisite power of developing details on broad areas greater than the vast majority of people.

I have not a word to say in favour of the "conventional plans which are to be found in every office and every big book on gardening," except that such plans may sometimes suggest a line of treatment suit-

in rings and dots" might have been better if the work had been left in the hands of one experienced in the study of pleasing effects and who could have prepared drawings showing such effects in such a way that the men working on the ground would have had it taken out of their hands to so spoil the landscape.

The assertion at the end of "W. R.'s" note is as individualistic as is the true art of gardening, and, having previously stated that he has never used paper plans he boldly states in the light of his experiences of them that it is a "complete delusion that plans for picturesque gardens can be made or improved on paper." Has he lost sight of the fact

that if "complete knowledge of the subject and the eye of an artist" are necessary, the pen, pencil, or brush of an artist may be very useful in conveying to others who possess neither the knowledge nor the eye what that knowledge teaches and the eye sees, and thus ensure that the right teaching and true perception are carried into effect.

WESSEX.

[I grant to the writer at once that the paper way is a professional one, but it is certainly not the best way. If he looks at activities of all kinds, and especially those of artistic aims, he will see that the professional way is not always by any means the best way. Of this many examples might be given, but let us take architecture, that of the Victorian up to the present day. A much-trusted architect told me that it pained him to see the work done in architecture in some of the most beautiful parks of the country. For buildings we must have drawings, but great harm has been done to building by showy drawings that falsify the garden, and we see the result of such work in all directions.

I give three examples of actual work in the hope of converting "Wessex" to my view:—

(1) I go to London by road sometimes, and pass, on the way, a piece of slightly diversified land, not naturally ugly, but certainly made so by what is called landscape gardening. It is bordered by a miserable wire fence, and is dotted all over with trees stuck in rings, with here and there, standing alone, an Austrian Pine or a big tree. The surface is broken up in a futile way, and breadth and simplicity destroyed. From the planting there is no shade, shelter, or beauty, and it has been done as hundreds of places have been done—from a few dabs of a water-colour drawing by someone in the office without experience of trees or knowledge of landscape. If this were seen in a few instances only it would matter little, but hundreds of acres in some of our fairest counties are thus disfigured. The laid-out garden is nothing compared with the lawn, park, or woods around a country place. If I wanted to change this place, what good would it do to go and survey it to have it planted again. I should only want a good woodman to cut the trees away and plant again. It could be done, of course, in the paper way at double the expense and delay, with the chance of the plan being made and judged of by the young man in the office.

(2) To go to another place—the garden at Hillbrook Place, which was illustrated in a recent number of this paper. It came about from a study of the ground in the first place. No plan of any kind was made, no plan could show the subtlety of the planting and the happy use of many beautiful shrubs and plants which are not known to the young man in the office. There was no paper design, and no paper plan could have arrived at the same result.

(3) Here is an illustration of a lake I have made myself, which tells its own story. It was an old "hammer" pond on a farm, and cattle crossed it from one side to the other, and there was a band of yellow clay round the edge where the waves dashed up. What good would surveying and making a plan of this have done? It would merely add to the delay and cost. Merely to make a plan of the whole now would be an elaborate labour without any use, except adding to paper rubbish. The ground near the pond was of very little value, and I had to enclose it to keep out rabbits and hares, and that was done on the ground itself by getting true lines

with a few sticks cut out of the nearest copse and making a quick fence.

Laying out on the ground can only be well done by one who knows all his materials—trees, shrubs, and flowers—and has an artist's delight in the work. But should anyone attempt such design without these credentials?

I shall say no more in print about this matter; but if "Wessex" comes to see me I will try and show him that paper plans are a very poor substitute for the earth itself.

W. R.

LILY OF THE VALLEY.

ALTHOUGH this hardy plant is so popular, it often does not get the treatment it deserves. Because it is of a hardy, enduring nature it is by many expected to furnish good flowers on the let-alone principle, and this it will do should the soil be of a favourable nature. Soils vary so much that a hardy plant may in one place thrive for some years undisturbed, whereas in another, periodical transplanting may be imperative. The Phlox is an instance. Where the soil is light and very porous, blooming acts in an exhausting manner, and fresh ground is necessary every other year if blooms of really good quality are desired. It is the same with Lily of the Valley. I have known beds last many years with very little attention, and produce flowers of very fair quality, but I have noted that the plants get a certain amount of shade, and something in the soil must have suited them. Those who grow for producing high-class flowers for the London markets must practise high culture. The form of culture, or rather want of it, which prevails in amateurs' gardens generally will not do for the market-grower. The flowers obtained in that way would fetch what market men term a "mere nothing." Judgment has to be used as to the duration of the beds. In some soils the plants will last longer in the best form than in others, but one cannot err in transplanting every fourth year, and in the case of light, porous soils it may be necessary to do so every third year, and the knowledge of this can only come from experience.

In the matter of growing for profit, soil and climatic conditions must be considered, and this holds good of all things cultivated for the London markets. Periodical transplanting, deep culture, and liberal feeding produce those fine samples which form a feature in Covent Garden Market. The ground for Lily of the Valley should be thoroughly stirred to a depth of 15 inches early in September, laying it up rough, breaking it down in the end of October, and adding some rotten manure, if it can be had, if not, some kind of artificial must be used, but this is better applied later on, hoeing it in just as growth appears. If old beds exist, the best crowns may be set out 6 inches apart, and if this is done at the time stated the crowns will be well settled in by winter rains and you will, the following spring, see a marked difference in the quality of the flower-spikes. The liberal culture will tell in the first season, and the following year there will be a full crop of top grade flower-spikes. Lily of the Valley grows naturally in the influence of protective vegetation. It is at home in the copse and woodland in company with the Anemone, the Bluebell, and Primrose—a pretty and happy combination of native flowers. I know of one place where this plant has been naturalised under such circumstances, and with success. In the southern counties I advise planting where the sun goes off about noon. Its growth is much more healthy when there is some protection from hot sun.

BYFLEET.

NOTES AND REPLIES.

Everlastings.—Although I am no great admirer of the so-called everlasting flowers, yet at times they are useful in winter, even with the increased number of things which bloom during the dull months. In the borders the Helichrysums may be grown, and if sown now, plants will be ready for putting out in May after there is no further danger of frost. For greenhouse work Rhodanthes are not without value, and from seeds sown in March good pieces may be bloomed in 5-inch pots. The best varieties for this purpose are R. Manglesi, R. maculata, and R. m. alba. When it is desired to preserve the blooms of these, or of Helichrysums, they ought to be cut when fully expanded and hung head downwards in a cool, dry place. When thoroughly dried they are useful for mixing with dried Grasses.

—KIRK.

The Bloodroot (*Sanguinaria canadensis*).—This is now in flower, the snowy blossoms, with their enveloping leaves, being very welcome. It is rather variable, the best variety being sold as *S. canadensis* major, with larger flowers. There is another form, known as *S. canadensis* multipetala, with a greater number of narrow segments, but I do not consider it any improvement on the others. I have generally grown *S. canadensis* in full sun for the sake of its flowers remaining open for the greater part of the day, as they close in dull weather and in the shade. It is increased by division in early summer or by seeds sown as soon as ripe.—S. ARNOTT.

Mignonette Golden Queen.—This is one of the best sets of Mignonette. Seed should be sown at once on firm land out-of-doors. It may also be sown earlier in heat and transplanted; indeed, in our cold district we are compelled to do this, and gain excellent results. If sown outside, the plants must be well thinned. Do the thinning as early as possible, and well water afterwards to settle the soil. It can, of course, be used as an edging, but a prettier effect is obtained if large patches of it can be sown or planted in the mixed border or a whole bed given up to it.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield.*

Crocus biflorus Pestalozæ.—Few Crocuses give us more variety than *C. biflorus*. Among the most acceptable varieties is *C. b. Pestalozæ*, which has several points of beauty. One of these is its small size; another its colouring—white, touched with yellow at the base. Maw says it is the albino form of *C. b. nubigenus*. His coloured illustration on Plate LIX. of his "Monograph," Fig. 4, does not do justice to this charming little Crocus.—S. ARNOTT.

Two good Gladioli.—The planting-time for Gladioli has again come round, and while the majority of these popular flowers are handsome, some of them are especially so. Two very telling kinds in groups are *Ida Van* and *Electra*, the former carrying stately spikes of salmon-red, the individual flowers of fine form. *Electra* is one of the best of the self-coloured Gladioli, the spikes more than ordinarily robust and the flowers of a bright scarlet.—KIRK.

Queen Anne's double Jonquil.—This is by no means a common plant, but is generally admired, even by those who do not care for double flowers. It has the usual narrow Rush-like leaves of the Jonquils, and the flowers are of a clear, warm yellow, and very double. Why it is not more cultivated seems surprising. Miss Bertha Anderson grows it admirably in her garden at Barksimming, where are to be found many rare plants.—Ess.

Hardy plants for cutting.—Nothing takes the place of these for cutting, especially where material is wanted for tall glasses. It is a good plan to grow in various aspects. For years, when needing a quantity of flowers for cutting, I used to grow many perennials in three aspects—on a warm border, in the open, and on a north border. In this way many things continued in bloom for three months.—J. C.

The double Amoor River Adonis.—This comes into bloom generally in March, but in some places earlier. It is later than the single form and of a different type of growth. It grows about 6 inches high, and has double yellow flowers with a greenish centre. A nice clump in one of the borders of the Royal Botanic Gardens, Edinburgh, was very pleasing the other day.—S. ARNOTT.

Anemone demissa.—A good Windflower from Yunnan which has been recently introduced is *Anemone demissa*, which comes near the Himalayan *A. polyanthes*. With me *A. polyanthes* is a splendid doer on a half-shaded part of the rock garden, but it never ripens seeds. In *A. demissa* the exterior of the flowers is flushed with blue; the growth is dwarfer.—S. A.

Tulip Prince de Ligne.—Among the earlier yellow Tulips, *Prince de Ligne* is now (April 19th) in good bloom, and, especially on a sunny day, is very bright. Useful in beds or borders, this Tulip also forces very well, and, having a naturally long stem, it is very handy for cutting.—W. MCG., *Balmac.*

Aubrietia Wallacei.—This old variety of *A. deltoidea* is one of the first to bloom, and, although not so large-flowered as the newer ones, is valuable for giving a bit of colour (a warm purple) in the early days.—Ess.

INDOOR PLANTS.

GROWING *v.* BUYING FLOWERS.

My gardener says it is cheaper to buy flowers than grow them. We supply the church and have a good stock of Chrysanthemums and Lilies. When these are over there seems nothing else but to buy. There are two heated greenhouses, which cost some £5 for winter heating.—JOHN M. CURZON, *Torquay*.

[As you already have the greenhouses, and incur some amount of expense in the heating of the same, and taking into consideration the favourable conditions under which you labour in regard to climate, there should be no great difficulty in keeping up a supply of flowers for the purpose stated from the time Chrysanthemums are over until Narcissi and other flowers are available for cutting outdoors.

As regards expense, it would no doubt be cheapest if but a limited quantity is required every week end to purchase them, but if a continuous and liberal supply is needed it would then, we think, be cheaper to produce them. Besides this, you would have the gratification of seeing your greenhouses furnished with plants, some in bloom and others on which the flowers would be in various stages of development, while when the cutting stage is reached any surplus remaining over after fulfilling the above-named requirements would, no doubt, be acceptable for the decoration of your own apartments. Due provision would naturally have to be made for the meeting of such a demand from the end of December until the end of March by potting or boxing up in the autumn such plants and bulbs as are adapted to the purpose. Callas, for instance, yield a great quantity of spathes over a long period in gentle warmth. Spiræas, too, of such varieties as *S. astilboides* and *S. japonica*, are also very suitable. Retarded crowns would be best for flowering in the depth of winter, while ordinary crowns would form a good succession. Bulbs alone would furnish a varied and continuous supply, commencing with the early-flowering varieties of Polyanthus Narcissus, after which would follow Tulips of the earliest blooming sorts. Then medium and late-flowering varieties of the latter would carry on the supply of these flowers till the end of March, by which time *N. poeticus ornatus* would be in bloom with you outdoors. Of Daffodils alone there are many varieties which are amenable to gentle forcing, and can, moreover, be purchased at a cheap rate. Of these, Trumpet major, Golden Spur, Princes, Empress, Emperor, Horsfieldi, and Sir Watkin are the names of a few varieties. *N. poeticus ornatus* must not be omitted as the blooms are highly prized for the purpose under consideration. The early-flowering variety of Gladiolus named The Bride is also easy of cultivation; it does not require much warmth, while the spikes of bloom are admirably adapted for arranging in an artistic manner. The foregoing are a few suggestions only as to what might be easily grown under the circumstances, but the list, if it were necessary, could be much extended.]

NOTES AND REPLIES.

Seeding Amaryllises which did not during the present spring bloom are being carefully attended to in respect of moisture. The foliage is occasionally sponged, and growth is encouraged as far as possible. The raising of Amaryllises from seed is interesting, and if there is nothing particularly noteworthy among the flowers they are always useful for decoration.

Bouvardias may be propagated now. I prefer root-cuttings. To obtain the roots for propagation the old stools should be shaken out, the thickest of the roots selected and cut up into short lengths. These should be inserted in pans of light, sandy soil and placed in the propagating pit, where they will soon begin to develop new growths.—G.

ROYAL HORTICULTURAL SOCIETY.

MAY 2ND, 1916.

QUITE an interesting exhibition was got together on the above-named date, when, in addition to the ordinary meeting, the annual show of the Southern Section of the National Arnicula and Primula Society was also held. While there were no features of outstanding merit, there were many good displays, including the brilliant lot of Rhododendrons brought from Falmouth by Messrs. Gill, the splendid lot of *Prunus pseudo-Cerasus Watereri* from Mr. Allgrove, and the display of Gentian blooms from Exeter, all worthy of special mention. Several important novelties received recognition. Following are some particulars of the show:—

ALPINE AND HARDY PLANTS.

Of these, the small collection staged by Messrs. R. Tucker and Sons, Oxford, contained many choice and rare examples, notably *Oxalis adenophylla*, *O. enneaphylla*, a lovely pan of the 2 inches high alpine Pink (*Dianthus microlepis rumelicus*) (Award of Merit), whose rounded, miniature, rosy-carmine flowers hid the tuft of glaucous leaves from view, *D. m. albus* which is more starry of blossom and white, *D. glacialis gelidus* (pale pink), *Ranunculus cortusæfolius*, *R. Sequieri* (both white-flowered species, far from common in cultivation), *Primula spectabilis*, together with *Androsace helvetica* and much else of interest to the lover of choice alpine. The true *Daphne arbuscula* (a rare kind) was also noted.

Messrs. John Waterer, Sons, and Crisp, Bagshot and Twyford, arranged an extensive bank of alpine, giving considerable prominence to the beautiful *Ethionema armenum* Warley Rose. *Daphne Verloti* is best described, perhaps, as a small-growing *D. Cneorum* of like colour and great freedom of flowering. The rare *D. petraea* (*rupestris*) was also in this group, and a superb lot of the too-rarely-seen *Draba* (*Petrocallis*) *pyrenaica*, the inch-high tufts freely flowered.

Mr. Clarence Elliot, Stevenage, showed a group of *Daphne petraea* (*rupestris*) flowering in pots. The greater attraction, perhaps, was the beautiful *Ribes crenatum*, which gained an Award of Merit. Only sprays of the plant were shown, these were, however, very freely covered with the maroon-crimson and pink flowers.

Messrs. Wallace and Co., Colchester, secured an Award of Merit for *Primula conica*, a new hardy Chinese species having drooping purple flowers in a dense head; both leaves and stems carry a short pubescence. A smaller-growing nearly-allied species was unnamed.

Mr. J. C. Allgrove, Middle Green, Langley, Slough, showed established pot-grown *Aubrietias* in variety. The examples, in 7-inch pots, were two years old, nearly a dozen plants of each variety being staged. In this way were such as *Eyrei* (a very old sort), *tauricola*, *Dr. Mules*, *Sonvenir de W. Ingram*, *Lilac Queen*, *Lavender*, *Fire King*, and many others full of bloom. The whole was backed by 4 feet long flowering branches of *Prunus pseudo-Cerasus Watereri*, one of the best of these plants.

Messrs. Barr and Sons, Covent Garden, W.C., showed *Saxifraga* (*Megasea*) *cordifolia* *purpurea maxima* (one of the best of the set), *Lencojum Hernandezi* and *Iris Haynei* (*Cushion*) were also remarked.

Mr. G. Reuthe, Keston, had the rare and beautiful *Schizocodon soldanelloides* (the reddish, drooping flowers deeply fringed), *Haberlea Frederici Augusti* (in more than one good form), *Mertensia angustifolia*, *Iris lacustris* (a rare miniature), *Ranunculus rutæfolius*, *Primula Forresti*, and other good plants.

Messrs. Whitelegg and Page, Chislehurst, showed *Silene pennsylvanica* (of good pink colour) and *Draba* (*Petrocallis*) *pyrenaica* very finely.

Messrs. T. S. Ware, Feltham, showed alpine extensively, including *Trilliums*, *Lithospermum*, *Aubrietias*, Mossy *Saxifrages*, *Lychnis Lagasceæ*, and much besides.

Messrs. Piper, Bayswater, showed a fine lot of *Lithospermum Heavenly Blue*, indispensable among good rock-garden plants. *Primula Queen Alexandra* (yellow), *Cytisus Daisy Hill*, *C. Dallimorei*, and others were in nicely-flowered examples.

Messrs. R. H. Bath, Limited, Wisbech, had a group of Polyanthuses (in crimson, white, yellow, gold-laced, and other colours) of a particularly good strain. Mr. J. Crook, Camberley, Surrey, had many of a shade savouring of reddish-orange and terra-cotta, which among fancy sorts is very remarkable. Among Polyanthuses it is an important break. Miss C. M. Dixon, Edenbridge, had an effectively arranged table showing well flowered examples of these plants in many colours.

Baker's, Wolverhampton, and Mr. G. W. Miller, Wisbech, also showed hardy flowers in variety, Messrs. Carter Page and Co., London Wall, staging an attractive collection of Tufted Pansies.

CARNATIONS.

Messrs. W. Cutbush and Sons, Highgate, N., showed particularly good flowers of their new red perpetual Malmaison Sabina, also Lady Ingestre (a lovely pink), Carola, and Mrs. Mackinnon (scarlet).

Messrs. Allwood Brothers, Haywards Heath, had vases of the new Dragon, Lady Miller (fine pink), Wivelsfield White, White May Day, and Mikado surrounding a central colony of the unique-coloured Mary Allwood.

Messrs. Stuart Low and Co., Enfield, had

magnificent examples of the new red perpetual Malmaison Hon. Charlotte Knollys, together with Alice, Mrs. C. F. Raphael, and Marmion, among many.

Messrs. W. Wells, Limited, Merstham, showed the new pink-flowered Lord Kitchener (Award of Merit), delightful in colour, of pronounced fragrance, and with tall, stiff stems.

ROSES.

Mr. Elisha Hicks, Twyford, had pot-grown examples of the single crimson Princess Mary and Mrs. George Norwood (both highly fragrant), together with stands of Mrs. John Foster (crimson), Ada Pauline (flesh-pink), and the fine single pink Queen of the Belgians. A Rose group on the floor from

Messrs. W. Cutbush and Sons, Highgate, N., was made up of Jessie, Mrs. W. J. Grant, Yvonne Rabier (a white cluster sort), Mme. Edouard Herriot, and others.

Messrs. B. R. Cant and Sons, Colchester, showed well of Cupid (a lovely flesh-tinted single), Rose du Barri, Mrs. Foley Hobbs, Mme. Cochet, and other good sorts. Rambler and pillar sorts were also prominent.

FLOWERING SHRUBS.

Messrs. R. Gill and Sons, Falmouth, showed a number of choice species and many good varieties of Rhododendrons. The finest thing was the giant cream and yellow K. Nuttall, half-a-dozen big trusses demonstrating its true worth. *R. glaucum*, *R. Keysi* (tubular, salmon-coloured flowers), a very good form of *R. Kewense*, *R. Aucklandi* (pure white), and *R. cinnabarinum* were all excellent. The brilliant crimson *R. Thompsoni* was very good.

Messrs. Fletcher Brothers, Chertsey, showed nice plants of *Deutzia discolor major*, a fine white introduced from China by Messrs. Veitch.

Messrs. J. Cheal and Sons, Crawley, showed a number of Magnolias in the cut state, *Soulangeana*, *alba superba*, *Lennei*, and *Alexandrina* among others.

GREENHOUSE FLOWERS.

Messrs. H. B. May and Sons, Edmonton, contributed Ferns, *Hippeastrums*, *Clematis*, *Hydrangeas*, and other plants. Messrs. Cannell and Sons, Eynsford, had a considerable collection of Zonal Pelargoniums in the cut state, also flowering examples of fancy and regal Pelargoniums in pots. Messrs. Stuart Low and Co. Enfield, had a considerable display of *Acacias*, *Boronia megastigma*, *B. heterophylla*, with *Streptocarpus* in several distinct colours, Messrs. Piper contributing *Azaleas*, and *Clematis* of sorts with *Acers* interspersed. Messrs. R. and G. Cutbush, Southgate, N., had many well-flowered examples of *Streptosolen* (*Browallia*) *Jamesoni*, with Tulips and Narcissi as a groundwork.

ORCHIDS.

Messrs. Charlesworth and Co., Haywards Heath, had finely-flowered examples of *Dendrobium infundibulum* (white), *Brassia Cattleya Bradshawia*, and the handsome *Miltonia vexillaria* Lyoth (rose-pink, blotched crimson).

Messrs. Sander and Sons, St. Albans, showed a variety of *Odontoglossums*, *Odontiodas* (very rich in colour), and the somewhat remarkable white-flowered *Angraecum infundibulare*.

Messrs. Stuart Low and Co., Enfield, staged well-flowered specimens of *Brassia-Cattleya Queen Alexandra*, *Cattleya Schroderæ Purity*, and *Harpophyllum spicatum* among many things. Mr. C. F. Waters, Balcombe, Sussex, showed beautifully-flowered examples of *Dendrobium nobile virginale* (a gem among white-flowered *Dendrobies*).

A complete list of the certificated plants and medals will appear in our next issue.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM APRIL 27TH.—*Cydonias* (in various colours), *Amelanchier Botryapium*, *Grevillea rosmarinifolia*, *Viburnum Carlesi*, *V. Lantana* (Wayfaring-tree), *Osmanthus Delavayi*, *Ribes sanguineum*, *Prunus* (in great variety), *Forsythias*, *Skimmia* (in variety), *Coronilla glauca*, *Rhododendrons* (in variety), *Chinese Quince*, *Exochorda Alberti*, *Periwinkles* (various), *Labrador Tea* (*Ledum latifolium*), *Sweet Gale* (various), *Berberis* (in variety), *Magnolias* (many), *Spiræa arguta*, *Andromedas*, *Hardy Heaths* (several species and varieties), *Double and single Gorse*, white and yellow *Broom*, *Daphnes* (various), *Camellias* (various), *Bush Honey-suckle*, *Colomia grandiflora*, *Veronica filiformis*, *V. pectinata rosea*, *Vesicaria utriculata*, *Doronicum*, *Lithospermum prostratum* *Heavenly Blue*, *Bellis carulescens*, *Brodiaea uniflora*, *Tulipa australis* and others, *Allium*, *Sandwort* (*Arenaria balearica*), *Erius*, *Omphalodes verna* (blue and white), *Corydalis* (in variety), *Geums*, *Tufted Pansies*, *Viola gracilis*, *Bloodroot* (*Sanguinaria canadensis*), *Hepaticas* (in variety), *Crown Imperial* (various), *Snakesheads* (in great variety), *Dicentra eaima*, *Romanzoffia sitchensis*, single yellow, white, and double *Arabis*, *Aubrietias* (various colours), *Honesty* (in variety), *Narcissi* (in numerous varieties), *Jonquils*, *Grape Hyacinths* (in variety), *Wind-flowers* (in great variety), *Bluebells*, *Algerian Iris* (*I. stylosa*), *I. cristata*, *Saxifrages*

(various), *Helichrysum bellidoides*, *Per-nettya serbica*, *Scillas* (in variety), *Chiono-dozas*, *Aponogeton grandiflorum*, *Caltha poly-petala*, *C. palustris*, *C. Tyermanni*, *Snowflakes*, *Auriculas* (various), the *Bardfield Orlip* (*Primula elatior*), *Foam-flower* (*Tiarella cordi-folia*), *Dog's-tooth Violets*, *Lily of the Valley*.

WORK OF THE WEEK.—Surplus plants of Giant Forget-me-not have been put in by the water-side and in other moist or boggy places. We always grow a few more Chicory than are required for kitchen use in order to provide a number of roots for grouping by the waterside. Many plants have been put out this week. This is a splendid plant for the purpose, the pale-blue flowers freely borne on stems each 3 feet or 4 feet in height, being always admired. The making of a small sandstone path has been completed, and a number of Michaelmas Daisies has been added to complete a long border containing a varied collection. The following plants have been added to fill vacant spaces in the mixed border:—*Dietamnus Fraxinella albus*, *Betonica grandiflora*, *Craspedia Richea*, and *Gypsophila venusta*. More Tufted Pansies have been planted among dwarf Roses, and *Primula Juliae*, of which a few plants were propagated last year, has now been put out in a shady spot. Everlasting Peas raised from seed last spring have now been put out among thinly-planted summer-leaving shrubs. The Bracken covering has now been removed from African Lilies, Crinums, and Sweet Verhena, and the ground will be forked over at the earliest opportunity. A site for Dahlias has been selected and deeply dug, and the ground among a number of herbaceous Phloxes has been cleaned and broken up. The plants are growing freely and should be given every encouragement from now onwards. Saxifrages have been broken up and planted among dwarf Roses. A few *Crocus Sieheri* have been lifted from a border and planted among the Grass. *Vihurnum macrocephalum* and *Carpentaria californica*, having outgrown their positions, have been lifted and replanted in a new piece of ground. *Olearia acicenniaefolia* and *Exochorda macrantha* have also been added. A large number of the tall Evening Primrose (*Eriogonum Lamarckiana*) has been planted out among Clematis, and a large plant of the Californian Tree Poppy (*Romneya Coulteri*) has been transferred to a sunny hed as the position previously occupied is now shaded by a porch which prevents it flowering freely. Seeds of Scabious, Lavatera, annual *Gypsophila*, Flax, Larkspurs, Mignonette, *Coreopsis*, *Gilia*, and Everlastings (*Helichrysum*) have been scattered among shrubs where vacant spaces occur. Beds containing dwarf Roses have been broken down to a fine surface, and Mignonette, Phacelia, Pimpernel, *Rhodanthe*, *Acroclinium*, *Clarkia*, *Swan River Daisy*, *Violet Cress*, *Alyssum*, *Gilia dianthiflora*, *Clintonia pulchella*, and other dwarf annuals have been sown, consideration being given to the colour of the Roses before sowing.

Sussex. E. M.

SOUTHERN COUNTIES.

Pot Vines.—Directly the berries begin to change colour a modification of previous treatment is necessary to obtain a perfect finish. The amount of humidity supplied by syringing and damping must be gradually lessened, as dry, warm air is essential for the colouring. Liquid stimulants must also be withheld in the same gradual manner, so that by the time the berries have more or less changed colour plain water alone will be the daily diet. A free circulation of air, which must be admitted from the front, though in less volume, as well as at the top of the house, is necessary whenever the state of the weather will allow of the ventilators being opened. When mild, a chink may be left on at the front all night, while the top ventilators should be left slightly open at night from the time colouring commences until the finish. Fire-heat at night cannot be dispensed with until the berries finish colouring, but when the day promises to be bright and an abundance of solar warmth available, it should be shut off in the morning. Damping of the floor is admissible during the forenoon and again when the reduction of air commences in the afternoon. When finished the temperature at night must be reduced from 65 degs. to 50 degs., and in the daytime to 55 degs. when dull, but when fine the house should be kept as cool as circumstances permit with the ventilators and doors open to their widest extent.

Early vinery.—A final scrutiny of the bunches when the berries have finished stoning and begin swelling off is a fixed rule, as it can then be seen at a glance whether there is ample space for all to swell to maturity without wedging taking place. The cutting out of a herry here and there, and in some cases it is confined to hut two or three, averts all trouble in future in this direction, while the scissors can be more conveniently manipulated now than later on. On the completion of stoning the final dressing of artificial manure is applied to the surface of the border and washed in with tepid water. Stopping of sub-lateral growths should be done regularly every week, this obviating all risk of a check, as happens when they are allowed to grow out and a knife has to be used. To assist the berries to continue swelling without check a certain amount of humidity is necessary. This is obtained by a free syringing of the walls and border surfaces and by damping the

floor in the early morning, at intervals during the day and again at closing-time. The maximum day temperature should be 80 degs. to 85 degs. with sunheat, 70 degs. to 75 degs. without it, and 60 degs. to 65 degs. at night.

Successional house.—This must be kept warm and fairly dry until the berries are properly set. A somewhat higher temperature is more necessary for the successful setting of Muscats than for Black Hamburgh, but when the two can be had in flower together less anxiety need be felt as to the ultimate result if the pollen of the latter is employed for the fertilising of the former. When the flowering is past the border should, if it is in want of moisture, be well watered when the bunches on each rod of Black Hamburgh, etc., can be reduced at once to the required number and thinning started as soon as the berries are well formed. Both operations are best deferred for a time, in regard to Muscats until it can be seen which of the bunches contain the least number of seedless berries, and so that none of the latter are left by mistake when thinning does take place. From now and onwards, dull days excepted, thinning is best done in the early morning and evening.

Late Vines.—With the assistance of a considerable amount of sunheat, late Muscats have broken well. They have also been disbudded, and the shoots stopped at the second leaf beyond the bunch, after reducing the bunches to one on each lateral. There being ample time between now and the middle of September for the crop to ripen, the vines will not be hurried, consequently the night temperature will not, until the flowering stage is reached, be allowed to exceed 60 degs., and that by day 65 degs.—i.e., with artificial aid. Other late varieties which are in a less forward state are breaking strongly and allowed to progress slowly; free ventilation and the employment of a minimum of fire-heat are the means resorted to for the prevention of a too rapid development of growth.

Figs.—The flowering stage being safely past, direct syringing can now be resumed without risk of water entering the apex of the fruits and causing them to decay and drop. They will now swell fast, and that they may attain to full size and have high quality the roots must be generously fed up to the time the fruits begin to ripen both with liquid-manure and artificials applied either from the surface or dissolved in the water. A great deal of nutriment will also be derived if a mulch of manure is placed on the border, the manurial properties of this being washed down whenever water is required. Early closing with a high temperature followed immediately by a copious syringing largely influences the rapid swelling of the fruit.

Later Figs.—The pinching of all young growths to induce the first crop to swell the more quickly as well as to expedite the production of a full second crop having had attention, the usual routine in the way of syringing, border watering, and ventilation will be adhered to. Tying of the young wood to the trellis is being done where opportunity offers. Pot trees with fruit fast approaching the ripening stage must be given a drier atmosphere and watered with plain water only. To avert a possible attack of red-spider during the ripening period, the floor of the house should be well damped daily in favourable weather.

Shelves.—Strawberry-forcing having been abandoned, all shelves in fruit-houses have been taken down and stored away.

Melons.—With brighter weather, which allows of the employment of a greater amount of humidity in the house, greater progress will now result, especially if the needs of the roots are properly attended to. Tepid liquid-manure and guano-water applied alternately will ensure the fruits attaining full size before they commence to show colour, after which plain water only must be given. To keep the foliage clean and healthy is of great importance, consequently both the under as well as the upper surfaces must be thoroughly moistened twice a day with the syringe. Lateral growths must be kept regularly pinched to concentrate the energies of the plants on fruit production alone. As the weight of the fruits increases it is necessary to examine the supporting net and see that the ties are quite secure.

A. W.

MIDLAND COUNTIES.

Fruit-trees on open walls will need more attention during the next few weeks than at any other season. Nothing is gained by allowing a lot of strong growths. By constant stopping fruit buds are formed and the trees rendered fertile. Where old spurs have been cut back on Plum or Pear trees and the shoots are coming away strong these should be stopped at the third or fourth leaf to induce them to form other spurs close to the main branches, these in time forming fruiting wood. An equal degree of vigour should be encouraged all over the tree, shoots not required being removed, so that the remaining growths may be strengthened.

Raspberries.—Old plantations will receive much benefit if a good mulch of farmyard manure can be given. Much good may also be done by watering with diluted liquid-manure. Remove suckers as they appear from between the rows, and thin out all weakly growths from the stools, retaining only suffi-

cient for the production of next year's crop. The autumn-fruiting varieties produce, as a rule, far too many growths. If these are not severely thinned the crop will be disappointing.

Strawberry plants that have been forced are now being thoroughly hardened before being planted out. Before planting out, the plants will be stood for a few minutes in water so as to thoroughly moisten the soil. Remove all runners and the crooks before planting, but do not break up the ball. Make the soil firm around each plant. The rows should not be less than 2½ feet apart, and the plants 2 feet apart in the rows. As soon as planting is finished mulch with stable litter or half-decayed manure, and in dry weather water occasionally until the plants are established. Very little attention will be needed until the fruit turns in in September, with the exception of removing all flower-stalks till the first week in August, and all runners.

Perpetual-flowering Carnations.—The main batch of plants for autumn and winter flowering has been given the final shift, using pots from 5½ inches to 7 inches in diameter, according to the strength of the plants and the vigour of the variety. The plants are now stood in cold-frames on beds of coal-ashes, and ventilated freely in favourable weather.

Malmison Carnations coming into flower are shaded from bright sunshine, abundance of air and occasional stimulants being given. The flowering-shoots should be neatly staked and the buds thinned to one on a stem as soon as they appear.

The flowering house is kept gay at this period by introducing the show and fancy Pelargoniums, also Ivy-leaved varieties, Fuchsias, Hydrangeas, Begonias, Gloxinias, Liliiums, etc. Primulas and Cinerarias that are over are cleared away, and Azaleas removed to a warm temperature and kept well syringed until they complete their growth.

Forced plants.—Hardy plants which have been forced, now that the outside temperature is more favourable, may be removed to the open under the shelter of a wall or hedge, where they may mature their growth before being again planted out. Plants forced this season should not be lifted next autumn.

Cinerarias.—A sowing of all the varieties of these will now be made. Seeds sown in shallow pans filled with a light compost of fine loam, leaf-soil, and coarse silver sand, placed in a pit with a temperature of 50 degs., will soon germinate. Avoid fire-heat if possible, and continue cool treatment throughout. *Primula sinensis* will also be sown now and treated similar to Cinerarias.

Climbing plants.—Special attention must now be given those that make rapid growth, as the shoots are very liable to be broken off by rough winds or become entangled. The aim should be to cover the supports without the least overcrowding, allowing some of the growths to hang loosely. In tying, allow plenty of room for the growth to expand.

The rock garden now requires much attention, taking care that strong-growing plants do not overgrow the choicer alpine. As Aubrietias go out of flower they will in places be cut back. The resulting growth will then, when sufficiently hardened, be available for cuttings, which should be dibbled into 3-inch pots filled with sandy soil, five or six in each pot. Place the pots in a cold-frame, keeping it close and shaded until roots are formed. In making Aubrietia cuttings do not remove the flower-buds, but allow them to develop, as this has a material effect upon their striking freely. A good selection includes the following:—*Dr. Mules*, *Fire King*, *Lavender*, *Lilac Queen*, *Moerheim*, *Mrs. Lloyd Edwards*, *Pritchard's At*, *Souvenir de William Ingram*, *Royal Purple*, and *Violet Queen*. As soon as the young growths of alpine Phloxes are sufficiently hardened they should be secured for cuttings. Treated in the same way as Aubrietias, they will root readily and make good plants to put out in the autumn.

Asparagus.—Careful attention must be given to the cutting of Asparagus as soon as it is ready. It is important that the shoots be removed from the bed whether required for immediate consumption or not. If tied in bundles and placed in an upright position on wet sand Asparagus may be kept in good condition for a week or ten days. When the supply is likely to be greater than the demand a hed or two may be allowed to run to be taken up for forcing next autumn or winter.

Cauliflowers.—Successional breaks will now be planted, selecting ground which has not been occupied by any of the Brassica family for at least twelve months. The earlier plantings are kept well watered with manure-water, and should the weather set in dry a mulching of stable-litter will be afforded.

Early Peas, owing to the long spell of cold weather, will be late this year. They may be forwarded considerably by pinching out the points of the growths as soon as a fair quantity of pods has set. Give plenty of water at the root and damp overhead on fine afternoons. Large sowings of late varieties will be made during this month to come in after the mid-season kinds. Trenches prepared as for Celery will be three parts filled with good rotten manure. Autocrat, Gladstone, and Ne Plus Ultra are all good kinds for this sowing, and generally succeed in most parts of the country.

BEST VALUE EVER OFFERED.

6d. a LOT; 1/2 LOTS, 3d. VERY STRONG TRANSPLANTED PLANTS AND CLUMPS TO FLOWER THIS YEAR.

Mrs. P.Y.M. Famous Fen-Grown Plants. 27TH SEASON.

PLEASE SEND BOTH POST AND RAIL ADDRESS.

Send for New Descriptive Catalogue of Hardy Perennials, Climbers, Vegetable Plants, Greenhouse Plants, &c. All Correctly Named.

Orders from 6d. to any amount can be supplied. Cash with order. An extra lot given with every 5s. order. Postage extra for small orders, 4d. for 2s. order or under. 5d. for 3s., and so on.

MAGNIFICENT HARDY PERENNIALS.

Acanthus, fine foliage 4 for 6d. Achillea, The Pearl, 6 for 6d. Aconitum (Monk's Hood), blue, etc., 3 for 6d. Agrostemma, Flos Jovis, 15 for 6d. Alstroemeria, Peruvian Lily, 4 for 6d. Lupinus, tree, yellow, white or mauve, 3 for 6d. Lupinus, new pink, 4 for 6d. Lupinus, blue or white, 9 for 6d. Lupinus, mixed, 12 for 6d. Lychnis, coronaria, 9 for 6d. Lychnis, new Salmon, 6 for 6d. Lychnis, scarlet, 6 for 6d. Lythrum superbum, 6 for 6d. Mimulus cardinalis scarlet musk, 6 for 6d. Montbretias, mixed, 15 for 6d. Onochea macrocarpa, very fine new dwarf variety, handsome large yellow blooms, 4 for 6d. Pansies, best exhibition varieties, Belgian, Odiers, Bugnots, Carriers, Covent Garden, English Prize, 12 for 6d. Pansies, all colours, separate, 12 for 6d. Periwinkle, blue, 4 for 6d. Periwinkle, violet, 3 for 6d. Pansies, giant flowering Trimardean, Parisian, Non Plus Ultra, Rival, etc., 15 for 6d. Paonia, mixed, 3d & 6d each. Paeoever Oriental, Apricot Queen, Salmon Queen, Mrs. Perry, Goliath, etc., 6 for 6d. Pentstemons, Scarlet Southgate Gem, Scarlet Newbury Gem, and Sutton's, Kelway's and Forbes' grand large flowering varieties, strong rooted cuttings, 4 for 6d. Pinks, coloured, 9 for 6d. Pinks, Her Majesty and Mrs. Sinkins, 4 for 6d. Pink, double white, 12 for 6d. Polyanthus, blue, 12 for 6d. Polyanthus, East border, 9 for 6d. Polyanthus, deep or pale yellow, very large blooms, 6 for 6d. Polyanthus Primrose, 6 for 6d. Poppies, Oriental, large crimson or scarlet, 9 for 6d. Potentilla, mixed, 6 for 6d. Primulas, lovely hardy varieties for rockeries, shady places, cool-house, pots, etc., Capitata, Cortusoides, Japonica, Malacoides, Krenessis, Florabunda, Sikkimensis, Verticillata, Bulliana Denticulata, 3 for 6d. Pyrethrum, double, new flesh pink, 2 for 6d. Pyrethrum hybridum, 4 for 6d. Pyrethrum roseum, 4 for 6d. Ranunculus, giant, 9 for 6d. Ribbon grass, variegated, 12 for 6d. Rocket, Sweet, 12 for 6d. Rose Campion, 15 for 6d. Rosemary, fragrant, 3 for 6d. Rudbeckia, double, 4 for 6d. Rudbeckia, Newuanu, 4 for 6d. Rudbeckia, new red, 2 for 6d. Saponaria ocycoides, 12 for 6d. Saxifraga, mossy, 6 for 6d. Saxifragas, very choice Bathoniensis, large flowering crimson and pink, also Muscoides superba small pink, 2 for 6d. Sedums spectabile, Azoon purpureocens, macrophyllum, large clumps, 3 for 6d. Scabiosa caucasica, 2 for 6d. Scabiosa japonica, 4 for 6d. Scabiosa, sweet, 9 for 6d. Shirley Poppies, 15 for 6d. Silene Schafra, pink, 6 for 6d. Spiraea aruncus (Goat's Beard), 2 for 6d. Spiraea Palmata, crimson or pink, 2 for 6d. Stachys (Lamb's Ears), 12 for 6d. Star of Bethlehem, 9 for 6d. Statice, Sea Lavender, 4 for 6d. Stokesia, new handsome North American border plant, perennial, showy double blue flowers, 4 for 6d. Sweet Williams, Dobbie's Auricula-eyed, 12 for 6d. Sweet Williams, Kelway's New Scarlet Beauty, 6 for 6d. Sweet Williams, Kelway's New Pink Beauty, 9 for 6d. Symphytum, creeping plant for shady places, 9 for 6d. Tritoma Saundersi, rich orange-scarlet, 1 for 6d. Tunica saxifraga, 15 for 6d. Valerian, crimson or white, 15 for 6d. Verbascum, d.f. or tall, 6 for 6d. Veronica gentianoides, lovely blue, 4 for 6d. Veronica spicata, blue, 4 for 6d. Viola Marchioness, and Snow Queen, splendid white, 9 for 6d. Viola admirabilis, 9 for 6d. Viola Cornuta, for bedding, rockery, etc., Kelway's Mauve Queen, Purple Queen, white and blue perfection, lovely for edging, 9 for 6d. Violas, strong, transplanted plants of the following varieties, mixed, Blue King, Duchess of Sutherland, Lady Majorie, Ardwell Gem, King Cup, John Forbes, Royal Sovereign, Kitty Bell, Pembroke, John Quarton, 9 for 6d. Violas, strong autumn struck, rooted cuttings, true to name, Maggie Mott, mauve self; White Swan, white self; Kitty Bell, blue self; Councillor Waters, purple self; Primrose Dame, yellow self; Kitty Hay, yellow self; Mauve Queen, self; Blue King, 6 for 6d. Violas, white, yellow, blue, purple, red, mauve, large flowering, 12 for 6d. Violas, giant flowering, blue, fragrant, blue, Princess of Wales, La France, The Czar and Marie Louise, 6 for 6d. Queen of Climbers, self-clinging Ampelopsis Veitchii, large with several trails, 6d and 9d each.

Pansies, giant flowering Trimardean, Parisian, Non Plus Ultra, Rival, etc., 15 for 6d. Paonia, mixed, 3d & 6d each. Paeoever Oriental, Apricot Queen, Salmon Queen, Mrs. Perry, Goliath, etc., 6 for 6d. Pentstemons, Scarlet Southgate Gem, Scarlet Newbury Gem, and Sutton's, Kelway's and Forbes' grand large flowering varieties, strong rooted cuttings, 4 for 6d. Pinks, coloured, 9 for 6d. Pinks, Her Majesty and Mrs. Sinkins, 4 for 6d. Pink, double white, 12 for 6d. Polyanthus, blue, 12 for 6d. Polyanthus, East border, 9 for 6d. Polyanthus, deep or pale yellow, very large blooms, 6 for 6d. Polyanthus Primrose, 6 for 6d. Poppies, Oriental, large crimson or scarlet, 9 for 6d. Potentilla, mixed, 6 for 6d. Primulas, lovely hardy varieties for rockeries, shady places, cool-house, pots, etc., Capitata, Cortusoides, Japonica, Malacoides, Krenessis, Florabunda, Sikkimensis, Verticillata, Bulliana Denticulata, 3 for 6d. Pyrethrum, double, new flesh pink, 2 for 6d. Pyrethrum hybridum, 4 for 6d. Pyrethrum roseum, 4 for 6d. Ranunculus, giant, 9 for 6d. Ribbon grass, variegated, 12 for 6d. Rocket, Sweet, 12 for 6d. Rose Campion, 15 for 6d. Rosemary, fragrant, 3 for 6d. Rudbeckia, double, 4 for 6d. Rudbeckia, Newuanu, 4 for 6d. Rudbeckia, new red, 2 for 6d. Saponaria ocycoides, 12 for 6d. Saxifraga, mossy, 6 for 6d. Saxifragas, very choice Bathoniensis, large flowering crimson and pink, also Muscoides superba small pink, 2 for 6d.

Sedums spectabile, Azoon purpureocens, macrophyllum, large clumps, 3 for 6d. Scabiosa caucasica, 2 for 6d. Scabiosa japonica, 4 for 6d. Scabiosa, sweet, 9 for 6d. Shirley Poppies, 15 for 6d. Silene Schafra, pink, 6 for 6d. Spiraea aruncus (Goat's Beard), 2 for 6d. Spiraea Palmata, crimson or pink, 2 for 6d. Stachys (Lamb's Ears), 12 for 6d. Star of Bethlehem, 9 for 6d. Statice, Sea Lavender, 4 for 6d. Stokesia, new handsome North American border plant, perennial, showy double blue flowers, 4 for 6d. Sweet Williams, Dobbie's Auricula-eyed, 12 for 6d. Sweet Williams, Kelway's New Scarlet Beauty, 6 for 6d. Sweet Williams, Kelway's New Pink Beauty, 9 for 6d. Symphytum, creeping plant for shady places, 9 for 6d. Tritoma Saundersi, rich orange-scarlet, 1 for 6d. Tunica saxifraga, 15 for 6d. Valerian, crimson or white, 15 for 6d. Verbascum, d.f. or tall, 6 for 6d. Veronica gentianoides, lovely blue, 4 for 6d. Veronica spicata, blue, 4 for 6d. Viola Marchioness, and Snow Queen, splendid white, 9 for 6d. Viola admirabilis, 9 for 6d. Viola Cornuta, for bedding, rockery, etc., Kelway's Mauve Queen, Purple Queen, white and blue perfection, lovely for edging, 9 for 6d. Violas, strong, transplanted plants of the following varieties, mixed, Blue King, Duchess of Sutherland, Lady Majorie, Ardwell Gem, King Cup, John Forbes, Royal Sovereign, Kitty Bell, Pembroke, John Quarton, 9 for 6d. Violas, strong autumn struck, rooted cuttings, true to name, Maggie Mott, mauve self; White Swan, white self; Kitty Bell, blue self; Councillor Waters, purple self; Primrose Dame, yellow self; Kitty Hay, yellow self; Mauve Queen, self; Blue King, 6 for 6d. Violas, white, yellow, blue, purple, red, mauve, large flowering, 12 for 6d. Violas, giant flowering, blue, fragrant, blue, Princess of Wales, La France, The Czar and Marie Louise, 6 for 6d. Queen of Climbers, self-clinging Ampelopsis Veitchii, large with several trails, 6d and 9d each.

Strong Transplanted Well Hardened Plants. Begonias, Herbaceous Calceolaria, Cinerarias, Chrysanthemums, all varieties and colours, Scarlet Salvia, red and yellow bedding Calceolarias, mixed Dahlias, choice Fuchsias yellow and white Marguerites, scarlet Pentstemons, heliotrope Coleus, 6 for 6d. Celery and Lobelia seedlings, 100 for 6d. Cucumbers for house or frame, improved Telegraph, 1 for 6d. Cucumber beds, Bedfordshire Prize Ridge, 6 for 6d. Tomato, Carter's Sunrise and Sutton's Perfection, 6 for 6d. Vegetable Marrows, long green and white, 6 for 6d. Strong Vegetable and Herb Plants from Open Field. Spring Cabbage, Winter Onions, Cos and Cabbage Lettuce, Pickling Cabbage, 100 9d. Rhubarb, Myatt's Linnaeus, and Kelway's best, two-year old roots, 6 for 6d. Sea Kale, 6 for 6d. Asparagus, Kelway's Giant and Conover's Colossal, strong, 100, 2/6. Sage, 9 for 6d. Thyme, 15 for 6d. Marjoram, 12 for 6d. Parsley, 20 for 6d. Mint, 12 for 6d.

Mrs. P.Y.M., F.R.H.S., 2, VINE HOUSE, WOODSTONE, PETERBOROUGH.

CARMONA. Contributes Strength to Plants. You can almost see them grow as they derive strength from assimilation of the splendidly suitable nutriment contained in Carmona. But it is at bearing time when the virtues of Carmona are most abundantly evident. Feed your plants on it and experience for yourself the greater enjoyment and profit Carmona attaches to gardening. CARMONA PLANT FOOD is recommended by best Seedsmen. Sealed bags—14 lbs. 4/6, 28 lbs. 7/6, 56 lbs. 12/6, 112 lbs. 20/- 4 lbs. 6d., 1-, 2/6. ROBINSON BROS., Ltd., WEST BROMWICH.

IF YOU ARE WISE DON'T START TOO LATE. NOW IS THE TIME TO INCUBATE. Poultry Breeding pays better each year. A few shillings invested produces sovereigns. "The American" Chick Hatcher 15-egg size, price 5s. Hatches above and rears below simultaneously. "The Reliance" Incubator. Thousands in use all over the World. 30-egg size, 7s. 6d. 60-egg, 10s. 6d. These are solid wood machines (not amateurs' toys), each ready for use, with thermometer, moisture tray, lamp, instructions, etc. Illustrated Lists Free. Address—Manager, Room City Incubator Trust 21, 22, Glasshouse Yard, Aldersgate Street, London. The latest day for receiving Advertisements is FRIDAY, 9 a.m.

WHY USE A SYRINGE?

When for a few shillings more a HOLDER-HARRIDEN PNEUMATIC SPRAYER (1) Will do ten times the work in a fraction of the time. (2) Will do it more completely, and more thoroughly, and with no waste. (3) Is as simple to use, far less tedious than hand, and will save its cost in a season's use. But be sure it IS a HOLDER-HARRIDEN Hand-Machine, with Automatic Spray Release, 21/6. Larger capacity Sprayer, as shown, from 46/-

THE HOLDER-HARRIDEN, LTD., 35, 37, Noble Street, London, E.C.

GARDENER (Assistant) wanted, able to use scythe; ineligible for Army. Wages 2s per week, with good house, nominal rent. Write, with particulars—MEDICAL SUPERINTENDENT, Great Barr Hall, near Birmingham.

TO ADVERTISERS.—Kindly note that the telephone number of "Gardening Illustrated" is Holborn 731.

Awarded Gold Medal, Anglo-American Exhibition. Commended by the Royal Horticultural Society.

For Destroying Weeds and Moss on Carriage Drives, &c. Used in R.H.S. Gardens, Kew, &c., &c. "ACME" LAWN SAND. Marvellous destructive effect on Weeds and Moss on Lawns. Fertilizes the Grass; no other manure needed. 7 lbs., 1/9; 56 lbs., 10/-; 1 cwt., 19/-; Carriage Paid on 56 lbs. and upwards. Other Garden Chemicals, prices and particulars on application.

THE ACME CHEMICAL CO., LTD. TONBRIDGE, KENT (Dept. C), and River Street, Bolton, Lancashire.

LION CYCLES, £5 5s. 0d. Cash, or 15/- with order and monthly payments. Signed Guarantee for all time. Packed in crate free and carriage paid. Since 1905 I have advertised in this paper, and have made and sold over 20,000 Machines. NO EXTRAS: Lamp, Bell, Pump, and everything included. Carriage paid. YOU CAN RIDE AND TEST THE MACHINE FOR 10 DAYS. IF YOU DON'T APPROVE, PAY ALL CARRIAGE. I have thousands of testimonials. Write to-day for copies and Catalogue, with illustrations and full specification.—GEORGE BEATSON, "LION CYCLE" WORKS, 85, MOSELEY STREET, BIRMINGHAM. Please mention "Gardening Illustrated."

Runner Beans.—As soon as the soil has become warmed the first outdoor sowing will be made on ground that has been deeply trenched and well manured. Well-manured trenches will be prepared as soon as possible, allowing a distance of 10 feet between each. These will be left until the end of the month for receiving the plants raised in boxes under glass, by which time the soil should be in a good workable condition. Great advantage is gained by raising the first batch in boxes and planting them out after being properly hardened. These will commence to bear much earlier than those sown in the open, and are practically safe from frost and the attacks of slugs, which often do much damage in the earlier stages of their growth. Best of All and Scarlet Emperor are the best and most profitable varieties I am acquainted with.

French Beans.—Large sowings of these will now be made on sheltered borders, and pods will be ready for picking before the earliest Runners. F. W. GALLOP.

SCOTLAND.

Vegetable garden.—All late Potatoes have now been planted. It is quite certain that failing to allow sufficient space in the case of late Potatoes is the cause of light crops, and, further, should disease appear, crowded-up haulm is infested in a very short time. A good sowing of Autocrat Pea was made in a drill 50 yards long. The quantity allowed was not quite 4 lb.—that is to say, about 2 quarts. In practice this is quite thick enough, for Autocrat is naturally of a branching habit, and if it be at all crowded the crop is never so heavy, and is more quickly exhausted than when the haulm has plenty of room. More Broad Beans were sown, the variety being Harlington Windsor. This sowing will be supplemented by at least three others at fortnightly intervals. Instead of sowing the Beans in drills I prefer to dibble them in, 6 inches from seed to seed. At times pheasants are troublesome when the Beans are drilled in, but they do not appear to find them so readily when dibbled in. Brassicas for midsummer planting were pricked off into nursery beds, and a good sowing of Turnip Golden Ball was made. A former sowing concerning which some doubts were entertained has germinated freely and looks very promising. Sown-out Parsley has germinated well, and some little thinning has been done, while plants raised in heat and afterwards pricked out into cold-frames have been put out. A look round showed that previously sown seeds, including Leeks, Onions, Carrots, and Parsnips, have come away very evenly. More seeds of Vegetable Marrows were sown, and plants intended for frames were moved from 5-inch to 7-inch pots. Celery seedlings for maincrop and late planting were pricked off on a partly exhausted hotbed, and as it is intended to make a new bed of Mint, a considerable quantity of cuttings was put in. Many prefer to lift rooted pieces of Mint for forming new beds, but I think cuttings develop into bushier and equally profitable plants.

Hardening off has now begun in the case of the more robust of the bedding plants. These are placed at present closely in frames, and on all suitable occasions the sashes are removed—indeed, if the thermometer is reasonably high in the neighbourhood of 10 p.m. the plants are exposed throughout the night.

Begonias for the flower garden, having now made excellent growth, were removed from the bed of Cocoa-fibre on which they had been started and planted out meantime in cold-frames. The soil in these frames was freshened up by the addition of a few harrowfuls of roughly-sifted leaf-mould, in which the roots soon get to work. For a short time the sashes will be matted up at night.

Hardy plants.—If for any reason it may be necessary to lift clumps of Kniphofias, the present is a very good time to do so. Let the station be of a good depth and circumference, and have it prepared in advance. After transplanting has been done, a good soaking of soft water will settle the plant, and a mulch of rotted manure will be of additional benefit. If it is intended to cut over or to divide any clumps of Pampas Grass there must not be any further delay. Similar precautions as in the case of Kniphofias should be observed. Large accumulations of *d'bris* in the stools of large pieces of Pampas Grass may quite safely be burned out. The plants may be a trifle unsightly for a time, but the growth at this time of the year is rapid and soon effaces the marks of burning. New Zealand Flaxes are benefited by a top-dressing of some good soil, or, preferably, by a mulch of manure. In any case, large plants require something to carry them on, unless they are planted in a rich and naturally deep staple. Although it is getting rather late, such things as Phloxes, Asters, Pyrethrums, and similar robust hardy plants may yet be divided or replanted with a fair prospect of success.

Gladioli.—The companion bed to that planted with Dahlias was filled with Gladioli. These were put out rather thickly, and after the bulbs had been planted *Eschscholtzia californica* was sown on the surface.

Plant-houses.—With more sun, more watering is now needed, and any plants which have obviously filled their pots with roots may be allowed occasional doses of liquid-manure or of chemical aids in solution. When a plant

after having been watered in the morning shows symptoms of flagging before night, it may be assumed that the roots have occupied all the soil or that the ball has become too dry. The remedy is easily found. In the first case, liquid-manure after a good watering; in the second, standing the pot in the tank for an hour or so. Ventilation must now be free, any closeness in the atmosphere being almost certain to result in outbreaks of insect pests. Fires may now be dispensed with in the greenhouse, and on bright days in the stove until night. By shutting up comparatively early, sun-heat will keep the stove fairly comfortable for some hours, but it is unwise to do away with fire-heat at night yet awhile. A check now may result in stunted plants at a later date. Stove temperature at night can be kept up now to about 68 degs. with quite a moderate fire.

Sweet Peas.—During the week a quantity of Sweet Peas was got out. This batch consists of the old grandiflora varieties, and was planted in a long line in order to screen a vegetable break. To prevent damage at present from wind a trench about 4 inches deep was taken out with the hoe, and in this the Peas were planted. As growth increases the soil will be returned, after which the plants will be staked without delay.

Hardy Chrysanthemums.—A long line was closely planted with hardy Chrysanthemums during the week. These are intended chiefly for cutting from, and as the situation is sheltered by a Beech hedge the early frosts at the close of September will do no harm to the plants. These will be supported with Spruce branches to form a hedge, and as the varieties—all of the Masse type—bloom simultaneously, a fine display, apart from the value of the blooms for cutting, may be relied upon.

Lavatera trimestris, var. splendens.—A good hedge of this showy and durable hardy annual was also made. Last season the mistake was made of sowing it in a very rich border, and as a result it grew to a great height—over 7 feet—and, while it made a magnificent show for a time, the autumn gales ruined it early in September. It has been now sown in a more sheltered place and in poorer soil. Other annuals sown some time ago are now appearing through the soil; and, in order to discourage slugs, dustings of soot are being given at intervals. Pricking off has now been almost completed. Ten-week Stocks and similar things pricked off at this time will soon make useful plants which will be ready for planting out in May.

Fruit-trees on walls.—So far, no frost of any great importance has been registered, and the outlook is encouraging. W. MCGUFFOG.

Balmie Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Plants for the wild garden (Tadworth).—In addition to the plants you mention, you may try the Winter Aconite, Anemone Robinsoniana, A. apennina, A. stellata, Fritillarias, Cornflower, Crocus, Crane's Bill, Cyclamens, Day Lily, Foxgloves, Grape Hyacinths, Lungwort, Meadow Saffron, Omphalodes, Plantain Lily, wild Roses, St. Bruno's Lily, Scabious, Scillas, Snowdrops, Snowflake, Solomon's Seal, Ornithogalum, Wood Lily.

Asparagus plumosus (A Reader).—The best and quickest method of growing Asparagus plumosus is to pot it in a good open compost, consisting of about two-thirds loam to one of well-decayed leaf-mould or peat, with an admixture of silver sand, and keep it in a stove temperature. Treated thus it will grow rapidly; but in a cooler situation, though its rate of growth will be slower, the shoots are firmer, and will last longer when cut. It is seldom satisfactory in a greenhouse temperature, and needs a structure which in winter does not fall below 50 degs. A shaded rather than a sunny position is most conducive to its welfare.

Removing foliage from bulbs (Daffodil).—It certainly weakens bulbs to remove them from the ground before the foliage has died down. If they have to be taken away to make room for bedding plants they should be lifted with as large clumps of soil as possible, and planted carefully in spare beds in the kitchen garden or elsewhere, care being taken to disturb the soil about their roots as little as possible. When they are in their new position should be filled in which they have been placed should be filled in and well watered, so as to solidify the soil round their roots. Leave them in this position till the foliage has ripened off, when they may be lifted, the foliage removed, dried, and kept until planting-time again comes round. However much care is taken, the bulbs are sure to suffer more or less from the shift.

Treatment of Gloxinia seedlings (Nil Desperandum).—Prick the Gloxinias off singly into small 60 pots, and place in a shady position on a shelf. Pay careful attention to the watering to prevent damping off. When the plants are well rooted and making good growth, pot on into larger pots. A 4-inch pot will be quite large enough for this year, as Gloxinias do not make very rapid root-action. We recommend fibrous loam, peat, and sand to pot in. Grow in a temperature from 55 degs. to 60 degs., and always keep shaded

from strong sunlight; also keep free from cold draughts. When finished growing and flowering, discontinue the watering a little, gradually drying off to ripen the bulbs. Afterwards place them on their sides in a dry position until the spring, when they commence growth. They should then be watered, potting on the same as the previous year. A little stimulant may be allowed once a week when the plants are well rooted.

FRUIT.

Pear-leaf blister-mite (H. F. W.).—The infested leaves should be picked off and the rest sprayed with some insecticide, as paraffin emulsion. Be sure that the insecticide is applied to the undersides of the leaves. It would be well, also, when all the leaves have fallen, to spray the tree with the caustic alkali solution so often referred to in these pages and the recipe for making the same given.

The black Vine-weevil (W. C.).—The beetle you send is the black Vine-weevil (*Otiorrhynchus sulcatus*). It is very injurious to the foliage of many plants—Vines and Ferns are special favourites. As they hide themselves very cunningly during the day, and only come out at night to feed, they are difficult to destroy. The best way of catching them is to place a white sheet under the plants they are feeding on, and, when it is dark, suddenly throw a bright light on them. This often causes them to fall. If it does not, shake the plants well, or examine them carefully. Their grubs are fat, fleshy maggots, which are very destructive to the roots of Ferns, Primulas, Cyclamens, Strawberries, and many other plants.

VEGETABLES.

Tomatoes outdoors (H. A.).—Sow the Tomato seed as soon as possible, either in a warm greenhouse, in which case place the pan in the warmest spot, or on a hotbed. Sow thinly in a compost of loam, leaf-soil, and sand, and do not overwater in their young stage. Pot on when the rough leaf has formed, and get them as forward as you can before the end of May. Then gradually harden off previous to planting outside. It is very important to get them forward for outdoor culture, and you will do better to plant them 18 inches or 2 feet apart, and keep them to one stem only, pinching back the lateral growths. Any ordinary loam will grow these. It is more a question of early treatment and a warm season than soil.

MISCELLANEOUS.

Painting hot-water pipes (R. W.).—You should paint your pipes with a mixture of lamp-black and boiled oil, made into the consistency of thin paint. Before applying it light a fire to warm the pipes, as the work can be done better and more expeditiously when there is a little heat in the pipes. This will effectually prevent rust. There will be a little smell from the oil at first, but it soon goes off if the pipes are kept warm until the material is dry. You must not use varnish of any kind on pipes that are heated in plant-houses, or serious injury might be done to the foliage of the occupants.

Utilising house-refuse for the vegetable garden (J. C. C. M.).—There are several forms of the ordinary household refuse which, either dug in or used after burning, are most useful for dressing the land, notably bones, fish heads, Turnip and other Green tops, also waste Cabbage leaves, parings of vegetables, etc. Soot, of course, is very valuable as a nitrogenous manure, fine dust also we have used with benefit, while the household slops, slightly diluted, are also useful. Now, when labour shortage and other complications make it more difficult to obtain a full supply of the ordinary manure, we are compelled to fall back on other things which are likely to be of benefit, and while we wonder what things really are of use, we can be sure of one thing, and that is that vegetables grow by absorbing the materials of growth mainly from the soil, and if we can return only the waste portions of vegetables we shall be at least putting back some part of the ingredients which have been previously absorbed to form the tissues of the plants.

SHORT REPLIES.

R. F. S.—The trouble is evidently due to the unripened wood, which, being very soft, has been injured by frost. Cut out all the bad pieces, and we think the plant will very soon recover and throw vigorous shoots from the base. We have had the same thing happen to a Dorothy Perkins Rose trained on a trellis. —A. G.—So far as may be judged from the leaves you send us, the trouble is due to cold winds, and with warmer weather they will come all right.

NAMES OF PLANTS AND FRUITS.

Names of plants.—M. K. Wallace.—The Bird Cherry (*Prunus Padus*).—C. L. G. F.—The drooping Star of Bethlehem (*Ornithogalum nutans*).

A CAUTION.

THE past winter was not a pleasant one, but it was not a severe winter by any means. The temperature was never at zero, and I am astonished, therefore, that some things suffered very much from a temperature which should not have hurt them. A frost of 16 degs., or about that, followed by very soft wet, open weather, caused things that had been happy for years, such as the Bamboos, to shrivel up. I was led on by Mr. Messel's example to put out things that I thought might do, such as the Lobster's Claw plant and a few others, and I find they have all given way before this slight frost. It seems, therefore, that some caution is necessary, and by far the best way I find is my first way of keeping only to things one knows to be hardy and taking our proofs from neighbours' gardens, if we can. The influence of region in our islands is very curious and instructive. A broken coast line invites us to plant things that do well with the nearness of the sea to comfort them, but it leads to many mistakes. Once we get away from the seashore—even a few miles—one finds quite a difference—things that will do well half-a-mile from the sea will not do at all four miles inland. One must be very wary indeed in our land, especially when planting trees and shrubs that come from better climates than ours. Such things may survive for a few years, and then all go. It follows that our experiments with such things should be on a small scale, though we must admit that many of them are much hardier than is generally supposed and acted upon. For instance, the Camellia is hardier than even the common Laurel, and all who care for it should plant it. I have it myself in perfect health and not protected in any way or encouraged by special soil or anything else. The trouble is the terrible old double kinds, which were common in greenhouses when the Camellia became so popular. The double form is not nearly so good as the single. I have no doubt that many of the single forms were thrown away in olden days when people thought of nothing but the double forms. So also the Lapageria, a splendid plant from Chili, which is hardier than many people think and does wonderfully well near the coast line in Wales and in England. W.

NOTES OF THE WEEK.

A Fairy Thrift (*Armeria cæspitosa*).—A Moss-like kind, with lovely pale lilac flowers. Plant and all about an inch high. From Sir Frank Crisp.

More prohibited imports.—In reply to a Parliamentary question by Mr. Needham, Mr. Pretyman said it was proposed in a few days to issue a further list of articles the import of which was to be prohibited, in order to secure additional tonnage space for essential needs. Among the articles affected are bulbs, flower roots, plants, trees, and shrubs, as also canned, bottled, dried, and preserved vegetables.

The Southern Heath (*Erica australis*).—This, the loveliest Heath of Europe, puts up with all our heavy rains in April, and, now, though knocked over a little by the storm, it is the most beautiful Heath of May. It is as good in effect in the house as it is out-of-doors. Anybody with time to look about the country where it grows—the south of Spain—might add to our treasures by finding varieties of it, one of which, the white, is now in cultivation.—W.

Primula leucophylla.—This species one does not often see in gardens, but it is well worth growing, and does not appear at all fastidious. Its habit is very much the same as that of the Cowslip, but the flowers are more drooping than in that species, and of a very pale yellow, even paler than in the common Primrose. Like most Primulas, it likes shade and not too dry a position, otherwise it is quite easily managed.

Narcissi in Scotland.—Looking round (May 7th) after a three days' storm of east wind and rain, it is disheartening to see the havoc wrought among Narcissi. Almost every variety represented is spoiled, even the Pheasant's Eye, not yet expanded, having shared the same fate as those in full bloom. It has been a cold and trying spring even in our comparatively mild climate, and I fear those less fortunately situated must have suffered more severely.—W. McG., *Balmac, Kirkcudbright*.

Iris stylosa.—What a long-flowering period this species has. My plants started blooming at the beginning of November, and ever since then they have been throwing up flowers almost continuously, the only times when they did not bloom being when the ground was frost-bound. The

blooming season is practically over now, but I noticed two flowers out on different clumps to-day (May 5th), so they have been blooming over six months. They are in a raised bed against a south wall in poor, gritty soil, and flourish very well.—NORTH LONDON.

Late Holly berries.—On the 22nd April my attention was drawn to a well-berried piece of Holly in a shrubbery. The berries were firm, plump, and well coloured, and the fact is interesting because, in a general way, Holly berries, owing to the attacks of birds, rarely hang after the New Year. Indeed, sometimes before that date the trees are entirely stripped. Missel thrushes are the chief enemies of the berries, and, curiously enough, these birds have never been more in evidence.—W. McG., *Balmac*.

Umbrella Plant (*Saxifraga peltata*).—This is now in flower by the waterside, where it forms a distinct and pretty feature. The flowers are produced in clusters, each from 4 inches to 6 inches in diameter, in colour a lovely soft peach-pink, with a deep red centre. The flowers are borne on stout, reddish, hairy stalks, each from 18 inches to 2 feet in length, before the leaves—which are the glory of this plant in autumn—appear. It is a grand plant for naturalising near a lake, stream, or for planting in boggy ground.—E. M.

Veronica laudiana.—I saw this described in 1913 as "the most beautiful of all; very scarce." I quite agree as to its great beauty. I wish some of your correspondents would say whether it is, as a rule, very tender, and requires protection in the winter. I had two plants in 1913—one in a sort of moraine, and the other on a rockery in deep, light soil, both facing west. Flower-buds were formed in February last, and both plants bloomed beautifully in the middle of April. They are under 1 foot in height.—E. CHARLES BUXTON, *Coed-Derw, Bettws-y-Coed*.

Anemone nemorosa Robinsoniana.—I have a considerable variety of blue forms of the Wood Anemone in my garden, yet, even although my allegiance may waver when it is attracted by a new variety with flowers of a slightly different hue, I always appreciate that now old but recognised favourite *A. nemorosa Robinsoniana*. To appreciate it properly it should be seen in a good clump, which can soon be secured in most gardens by leaving the plant alone.

I grow A. n. Alleni and several other good blue Anemones, but A. n. Robinsoniana is the best.—S. ARNOTT.

Rhododendron glaucum.—A dwarf and very pretty bush with many pale rose flowers; fragrant. An excellent rock plant. From Sir Frank Crisp.

Spring gardening economy.—I understand that some very showy gardens are given up this year owing to their great cost. The usual way of spending a lot of money to adorn the garden in spring is stupid and unnecessary. Any system of gardening that calls for renewal every year must involve much cost and labour. I have in Grass now some millions of flowers—Narcissi, Crocuses, Grape Hyacinths, and others—which have never cost anything for renewal or labour. Such things have to be adapted to the soil no doubt. I have a wood which is a picture now more than any garden.—W.

Viburnum Carlesi.—This, now (April 29th) in full bloom, is undoubtedly a valuable introduction. It makes a shapely bush, its tube-like flowers, produced in terminal, rounded clusters each 3 inches across, being pink in the bud, gradually becoming white as the blooms expand, and quite as fragrant as the best of the Daphnes. So far it appears to be quite hardy, and has come through the past trying winter unscathed, whereas many other shrubs have suffered severely. As a flowering shrub which does not require a vast amount of room to develop this deserves attention.—E. M.

Rhododendron cheiranthifolium.—Messrs. John Waterer, Sous, and Crisp, of Bagshot, tell me that a Rhododendron planted here in 1893 is R. cheiranthifolium. A few flowers were produced every season in April, but it never made much progress. Last summer it started to grow vigorously, and quantities of buds, which began to open early in April, were formed. I suppose there are now at least 200 blooms, and I never saw anything prettier. The plant never had any manure or top-dressing, so I suppose the warm, wet weather in the autumn, and especially in December and January, was the cause of the present success. There were also no severe frosts. Fifteen degrees on the Grass was about the worst we had.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed.*

Notes from Yorkshire.—When I left Yorkshire in early April there were but few plants in bloom, but now (May 3rd), beds, borders, and rock gardens are gay with flowers. The following list of plants now flowering (compiled from my own and several other gardens in this district) may be of interest to your readers:—Saxifragas in great variety, Aubrietias, Fritillarias, Daffodils in great variety, Alyssums, Arabis, Doronicums, Geum Heldreichi, Adonis amurensis, Anemones, Athionema iberideum, Hepaticas, Iberis sempervirens, Polyanthuses, Primulas in great variety. Wallflowers, Tulips, Scillas, Grape Hyacinths, Hyacinths, and Forget-me-nots are also in bloom. People say that spring is late this year, but it is early to have some of the above in bloom by now in this cold district.—E. T. ELLIS, *Wetwood, Ecclesall, Sheffield.*

Trillium grandiflorum.—I put half-a-dozen plants into a somewhat shady bed in the spring of last year, giving them a compost of old gravelly leaf-mould, made from the leaves swept up from the gravel paths each autumn and thrown into an old brick pit to rot for two or three years. I find this makes splendid soil for many alpine, as it is rich and at the same time porous and gritty. The Trilliums were in two little clumps of three each, quite near

each other, and one clump has done very well, the plants increasing in size and the flowers large. The other clump, though apparently growing under exactly the same conditions, is not doing so well, although each plant is blooming. The flowers are of a lovely pure white and very refined looking.—N. L.

The white Garland Flower (*Daphne Cneorum alba*).—This is a welcome addition to the forms in cultivation, and I look forward to see it thriving. From Sir Frank Crisp.

Salix vittelina var. britzensis.—This is often grown for its beautiful red bark in winter, for which purpose it has no peer, especially if cut down annually. Its attraction when in flower deserves greater recognition on the part of planters. A group of large specimens of this Willow growing here (Sussex) in a boggy piece of ground is a charming feature in the landscape, winter or summer. These trees are now bearing myriads of bright yellow catkins, each about 2 inches long and produced from the axils of every leaf, the trees a mass of yellow. One of these specimens, 60 feet in height, was brought down by the recent gale, and as the tree was lying prostrate I was astonished at the quantity and brightness of its flowers. Some of these were cut for the house, but, beautiful as they are when first cut, the leaves flag quickly. A dark green background is necessary to set off the rich yellow of the flowers.—E. M.

Cannas.—Where Cannas succeed out of doors they make stately and handsome groups, but when they cannot be so employed, owing to exigencies of climate, they are equally well adapted for greenhouse or conservatory decoration. As is well known, the seed of Cannas is very hard, and unless steeped in hot water, or filed, is very slow to germinate. Occasionally, when the roots are stored in rather a dry atmosphere they, too, are slow to start into growth when introduced into heat in spring. During the past winter an experiment was made with two lots of Cannas after they had flowered and ripened off their foliage. The first lot was stored in the orthodox way and permitted to get quite dust dry in the pots. The second portion was kept not by any means moist, but received occasional waterings throughout their period of rest. The result of the experiment has been informative. The roots, which had been, from time to time, watered, when put into heat came away almost immediately, and, at the present time, are far in advance of those which were entirely dried off. The point may be of interest to others who are interested in the Canna, either as an inside plant or for the outdoor garden.—W. McG.

Rhododendron fastigiatum.—This is one of the more recently introduced Chinese Rhododendrons, seeds having been received from Mr. Forrest in 1911. It was collected in Western China, where on certain mountains it is said to form a considerable part of the shrubby vegetation. In many respects it resembles the pretty blue-flowered R. intricatum, which was introduced a few years before, being of low, compact growth, about 1½ feet high, with small evergreen leaves. The flowers, larger than those of R. intricatum, being an inch or so across, are bluish-purple in colour and very attractive, for they are borne freely by quite small plants. It is an excellent species for planting on rock-work, where it may be grown in large or small groups. Like many more of the dwarf Rhododendrons, it can be increased quite easily from cuttings of short, half-ripe shoots inserted firmly in pots of sandy

peat in a close and slightly warm frame in summer. It is also easily grown from seed, which should be sown as soon as ripe. The seedlings flower whilst quite small. Although seeds were only introduced in 1911, plants flowered, out of season, in the autumn of 1912. The proper flowering time is April.—D.

The Daffodil.—It seems a pity that the cultivation of this charming flower has now developed into quite a craze. In some of the horticultural journals one reads column after column descriptive of new varieties and their supposed points of difference. They may be counted by the score or hundred, every one of which is thought to be an advance on that gone before. The specialists buzz around them at exhibitions, measuring this and comparing that, and if a flower is an eighth of an inch longer or wider than another the claim for novelty is supposed to be sufficiently justified. So numerous are the so-called new varieties that names for them in some cases seem to be exhausted, and they are now known by numbers. How many sections the Daffodil is supposed to be divided into I cannot say, yet there always seem to be differences of opinion as to which class some variety or other should be placed in. The fact is that Nature draws no hard and fast line, whatever arbitrary ones man may set up. It follows as a matter of course that when flowers are crossed and intercrossed any dividing lines are soon broken down. Signs are not wanting that the Sweet Pea is falling from the lofty pinnacle on which it was placed by some, and the Daffodil craze is likely to follow suit, though, as a charming outdoor flower and a delightful harbinger of spring, the old, well-tried sorts will always hold their own.—K. R. W.

Iris reticulata.—It is not likely that anyone can better the instructions given by Mr. W. R. Dykes for the treatment of this lovely plant. "As to cultivation," he says, "all that can be said is that shelter from wind is advisable. . . . It is impossible to say that any particular soil is more suitable than another, and except that humus in some form may with advantage be added to a very poor soil, no directions can be given." ("Irises," "Present Day Gardening," page 11.) To this I would only add that, like many other bulbous subjects, this Iris seems to derive much benefit from wood-ashes which have never had the potash washed out of them by exposure to wet. Nine years ago I planted a dozen bulbs in gravelly loam, without lime, at the foot of a south wall. These have had a shovelful of wood-ashes thrown over them once or twice. They have grown into a large clump, which produced over one hundred blooms last February. Mr. Dykes would recommend lifting and replanting, but I fear this is impossible, for the bulbs are inextricably entangled in the roots of a large *Sophora* (*Edwardsia*) *grandiflora*. I incline to think that much of the trouble met with in dealing with this and many other bulbs—American *Erythroniums*, the smaller *Fritillarias*, etc.—arises from the feeble condition in which they arrive after lying in the dealer's store. This can only be overcome by potting them and keeping in a cold-frame till they have recovered a plump and healthy appearance.—HERBERT MAXWELL, *Monreith.*

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

PLANTS AND FLOWERS.

ROOM AND WINDOW.

HARDY FLOWERS FOR THE HOUSE.

IN the old days we used to think hot-houses essential to the supply of cut flowers for the house, but where there is a fair number of good hardy flowers much may be had in that way for the decoration of the house. This year, in spite of the inclement spring, we began to find hardy things quite useful, as in the case of this noble Kingcup (*Caltha polypetalá*) and the Forget-me-not shown with it. This is not the Wood Forget-me-not, but one rather nearly allied to it—the *Myosotis*

changes is truly remarkable. Cold winds, heavy rains, and snowstorms such as we have this year experienced have absolutely no effect on the blooms. This little Anemone is one of the most valuable hardy flowers in cultivation, and should be made note of by window gardeners. A plant that will bloom freely in the open in the most inclement months of the year will be at home in a cool room. I strongly advise your readers who have not the means for forwarding things in artificial warmth to try this little Windflower. In growth it is ideal, the deep green foliage covers the soil, and the pale blue blossoms, which are freely produced, stand up well above it. Put three or four bulbs into a $\frac{4}{2}$ -inch pot not later than November, in

foliage with profusion and quality of bloom. This is really a fine thing for window gardeners, as the habit of growth is perfect, while the handsome trusses of bloom, of a soft, pleasing shade of pink, are thrown up boldly above the foliage. Although rather slow of growth, it is by no means "miffy," but has a sturdy, much-enduring nature. The slowness of development is an advantage in the case of a window plant, as Zonals and many other things outgrow their quarters and have to be much pruned or discarded. This variety can be kept in the same pots for two or three years without suffering any loss of blooming power if fed in the growing time, which is another point in its favour. The old Happy Thought, with

The Pontic Kingcup and Swiss Forget-me-not in Japanese basin.

dissitiflora, Swiss kind. It is very useful indeed, not raised from seed, but increased by division. It is rather apt to die out if not frequently divided.

WINDOW PLANTS.

ANEMONE BLANDA.—The worst time for window gardeners is, of course, the first two months of the year. Narcissi, Hyacinths, and Tulips do not come into bloom until March is well advanced, that is, if they have to come on in the natural temperature of the dwelling. With me *Anemone blanda* expanded its first blooms in the last week in January, and was effective up to the middle of April. The power of resistance which this charming little hardy plant displays to weather

nice, free soil, and stand them in a cool room, but never in a constantly-heated apartment.

VARIEGATED PELARGONIUMS.—It is a curious fact in connection with these that they are almost immune from the damping that is the worst enemy of the plain-leaved kinds, and for this reason they are very suitable for windows. Those old kinds, such as *Flower of Spring*, are, I think, much neglected by window gardeners, probably because they do not produce big trusses of bloom, but they are compact of growth, need but little pruning back, look very nice in winter, and form a pleasing contrast to other things. The gem of this silver-leaved section is *Mrs. R. Parker*, which combines beauty of

its quaint markings, is one of the best. It keeps its character in a living-room all through the winter. *New Life* is more delicate, is very dwarf, and lavishly variegated. It is a pretty little kind, and does best in pots and in rather lighter soil. If overpotted it is apt to die away in parts in the dull months. That old and still unrivalled Ivy-leaf, *L'Elegante*, is a most satisfactory plant. It may be kept in the same pot for several years with a little feeding. The variegation is good and constant, and, unlike many variegated things, it has flowers of good quality which are freely produced. It is really an admirable plant for growing all through the year in the house.

ANNUALS FOR WINDOW-BOXES.—Economy

being the order of the day, it may be well to direct attention to the fact that window-boxes may be effectively furnished without having recourse to Zonal Pelargoniums, Lobelias, and other tender things commonly used for this purpose. I have seen window-boxes filled with the common Nasturtium and Tropæolum canariense, and very fine they looked, the shoots hanging down in festoons and smothered with bloom. The taller-growing annuals, such as Clarkias, Godetias, etc., are not suitable, as they may be broken off by rough winds, but there are many of prostrate habit, such as Nemophila, Eschscholtzia, scarlet Linum, Dianthus Heddeewigi, Virginian Stock, Phacelia, and Nemesias, which will keep up a display through the summer months. No special compost is needed; any free garden soil that has been well sweetened will do.

FUCHSIAS.—If these have not been pruned they should be seen to at once. It is late for the operation, but better be a bit late than let them run up into a loose, weak growth. Cut into the preceding year's growth, and, when they break, shake away all the old soil and repot in a nice, free, fairly rich compost, watering very carefully for a time.

BYFLEET.

ORCHIDS.

Ceologyne cristata.—I should be very glad to know how best to ensure that the *Ceologyne* of which I am sending a flower and bulb should flower freely as it ought to do. I have pots and pans full of bulbs, but no flowers. Should it be kept dry at certain seasons? I should be grateful for any hints as to management.—MRS. T. B. KENNEDY.

[This generally blooms in March, but if it is grown under warm conditions the flowering period will be a month or six weeks earlier. After the spikes are cut, new roots will soon appear at the base of the young growth, when any repotting or top-dressing may be done. The plants only need repotting at rare intervals, but a little top-dressing may be done annually if the old soil is decayed. An average temperature of 60 degs. Fahr. should be maintained throughout the growing period, and the plants must be kept well supplied with water, while shade from all direct sunlight is necessary. The resting season begins directly the pseudo-bulbs are fully matured, when the temperature should be from 50 degs. to 55 degs. Water must not be entirely withheld, and no hard-and-fast rules can be laid down in this direction, as so much depends upon the intelligence and observance of the grower. The object should be to just keep the pseudo-bulbs from shrivelling, and even when growth begins water ought not to be applied frequently, or both growth and scape may decay.]

GARDEN PESTS AND FRIENDS.

Bean leaves unhealthy.—Can you tell me what is the cause of the brown spots on these Bean leaves? Is it Bean-rust (*Uromyces*), and, if so, is there anything to be done? It has attacked plants in every row, though not all the plants, and that I send is one of the worst specimens. March here has been very bad—snow every day—and as everything had pushed forward in January, which was exceptionally mild, perhaps the trouble may be due to the weather.—R. N. FERRALL.

[We do not find any of the Bean-rust on your Broad Beans. The damage has probably been caused by bad weather, and, if so, no doubt the Beans will grow out of it to some extent. Similar symptoms are sometimes caused by trouble at the roots, but your specimen being incomplete does not enable us to ascertain whether all is right there. In future when sending queries please write on one side of the paper only.]

GARDEN FOOD.

BOTTLING TOMATOES.

(REPLY TO "L. C. D.," PAGE 180.)

BOTTLING Tomatoes offers no difficulty. Select firm, fleshy fruit, of a small or medium size, as these pack better in the bottles or jars. They should be perfectly ripe, but not at all soft, and, if possible, freshly picked on a sunny day. Do not wash the fruit, but if at all dirty wipe with a damp cloth, dry with a clean one, and set in the sun for fifteen minutes. Some housewives use large bottles or receptacles, but I find a bottle containing sufficient Tomatoes for either one or two cookings better than the larger size. Once the jars or bottles are opened it is difficult to keep a large quantity of Tomatoes in good condition until all are used up. If, however, the Tomatoes are bottled for trade purposes the best selling size of bottle has to be considered. Where expense is no object, it is just as well to buy a special steriliser for cooking the bottled fruit, and a six-bottle size is a useful one for family use. These sterilisers can be heated by a gas jet, and the whole of the work can be done on a table. I always use the homely copper or a boiler placed on the stove. A fish-kettle does very well. Naturally, screw-top bottles are best, but I frequently bottle the Tomatoes in any large-mouthed glass jars and bottles I can procure. I have found the glass jars in which the large French prunes are sold do very well, but with these I employ the mutton-fat method of bottling.

The bottles must be perfectly clean, and it is as well to sterilise them by holding each over some burning sulphur so that the fumes will fill the bottle and kill any germs of fermentation lurking in the crevices. After this, put them all into the oven or on the top of the stove to get very hot. The skins can be left on the Tomatoes, but for home use it is better to remove them, as then the fruit can be packed rather tighter. Place a quantity of the fruit in a large colander and dip the whole for two minutes into some fast boiling water. This loosens the skins and they peel off very easily. Fill the bottles quite full, pressing the fruit down slightly, otherwise there will be many spaces between the Tomatoes. Do not crush the fruit too much or the beauty of the whole will be spoiled. When filled, stand the bottles on the stove until very hot. Have ready some actually boiling water in which sufficient salt to flavour has been dissolved, and pour this over the Tomatoes. The bottles must be quite full and no air-bubbles must be left anywhere between the Tomatoes. Now place the screw-tops and corks in position, and tie a cloth over the larger jars. Stand these latter in the fish-kettle, and surround with boiling water. Place the whole over the fire and cook until the Tomatoes show a very slight tendency to leave the bottom of the bottle. It is difficult to tell the exact time, as some Tomatoes cook quicker than others. Have ready some melted mutton suet, remove the cloths from the mouths of the jars, and pour an inch layer of fat on the top of the fruit. Stand the jars on a cloth-covered table and when quite cold tie parchment paper over the top and store in a very dry cupboard or larder. The layer of fat must not be broken until the Tomatoes are used, as otherwise they will not keep. The screw-top and corked bottles can be placed in a copper, with some wisps of hay laid between to prevent breaking during the process of boiling, and then fill the copper with boiling water, place the lid on top, and make a moderate fire underneath. Cook until a thin line of

water appears at the bottom of the bottles. Take up, see that the screw-tops are firm, and corks well fixed, and when cold store in a dry place. Some housewives use vinegar or acetic acid dissolved in water instead of the salted water, but the fruit absorbs some of the acid during the process, and this detracts from its usefulness for cooking, besides being much more expensive. If carefully bottled, Tomatoes will keep for many months, and probably for years. H. THORBURN-CLARKE.

NOTES AND REPLIES.

Lettuces.—I suppose each has his fancy as to the materials that go to make a good salad. With the exception of a tiny bit of Mustard and Cress, just the suspicion of young Onions, and a slice of Tomato when available, I care for nothing but a good Lettuce, and, that being so, try for a constant supply all through the season. The garden, being small, I rely solely on the Cabbage types. One row of Tom Thumb or Commodore Nutt is useful for the first cutting, but for the remainder of the season I use Golden Queen and Perfect Gem, both types of what a thoroughly good Lettuce should be, hearting well, with little or no waste, crisp, and standing as long as one can reasonably expect. With little opportunity for watering, I choose a partially shaded spot, draw the drills, soak with water if the ground is dry, sow as thinly as possible, and thin the plants to 8 inches or 9 inches. Birds are apt to be troublesome, so, as forewarned is fore-armed, some twiggy sticks are laid along the rows until the young plants are out of danger. A bit of short Grass is shaken between the rows while the plants are yet in a young stage, to obviate the necessity of watering. One occasionally has a slight break in the supply, but this is generally the fault of overlooking the time for the successional sowing. The sorts above named, with Continuity, are much more profitable for small gardens than the big-leaved, straggling kinds.—E. B. S., *Hardwick*.

Kohl-Rabi stewed.—Tender and fine-leaved Kohl-rabi might well be more cultivated on this side of the Channel, and it should be sown and then transplanted in May or June. Besides providing the orange-like bulbs, the greens in late winter are delicious. Here is a recipe for cooking both roots and greens. Peel and quarter the root of a Kohl-rabi, cover with cold salted water, and boil until tender; then cut the quarters into dice. Put the tops into cold water for a short time; drain them, chop them, and fry them in butter. Then add to them the diced roots; season with salt and pepper, and add about $\frac{1}{2}$ pint of stock. Stew until the vegetables are quite tender; thicken with a little browned flour, and serve immediately.

BAKED KOHL-RABI.—Peel, cut into slices, and parboil in salted water a Kohl-Rabi. Drain the slices and put them into a buttered casserole. Sprinkle with salt, pepper, and bread-crumbs. Moisten with milk or stock, and bake until brown.—*Guardian*.

Salade des légumes.—In a note about salads recently I left out one important one, which is the French *salade des légumes*. This is one of the best salads for the hot weather, and is often made of cold Peas, Beans, and other vegetables, with a light dressing.—W.

Onions.—For many years we have been so accustomed to an abundance of these that we take badly to the high prices they have made of late. A greengrocer lately told me he had bought Onions in Covent Garden some few years ago at one quarter the price he was now paying. In the light, sandy soil I have to deal with, Onions are not a profitable crop, the best results being obtained by sowing in boxes and planting out. Where Onions are difficult to grow, then Leeks should be grown.—DORSET.

TREES AND SHRUBS.

THE POPLARS.

THE Poplars are essentially moisture-loving trees, for although they grow well in ordinary garden or park land, development is most rapid when they are planted in the vicinity of water, and, like the Willows and Alders, they give good results in swampy ground or in land that is subject to periodical flooding. A short time ago a very wet area of land was pointed out to me in the north of England from which a crop of Poplar trees had recently been removed. From its appearance the land must have been valueless for ordinary purposes, yet many fine trees had been grown which, at fifty years of

foliage, and flowers may all be considered. The fastigate habit of the Lombardy Poplar, for instance, appeals to many people. It is also of value for planting in places where trees of a wide-spreading habit would be out of place. The European and American Aspens, again, are excellent for garden planting, their dainty quivering leaves being always admired. The white Poplar and its varieties, also the grey Poplar, may well be planted for their light-coloured bark and silvery or grey foliage. The Balsam Poplar is worth growing for its fragrance, whilst the flowers, particularly catkins of male trees, are often very beautiful.

Most of the Poplars are easily increased from cuttings of year-old shoots cut to the length of 12 inches and inserted in a border out of doors. The Aspen group is

those recommended for commercial planting are indicated, but perhaps better than the species are certain hybrids which are more vigorous than their respective parents, growing more rapidly and producing timber more quickly than the species. Prof. A. Henry, of Dublin, has interested himself a good deal in hybrid Poplars, and in addition to the old hybrids, he has raised, during recent years, a number of new ones, which are making remarkably rapid growth and promise to become valuable for commercial planting.

P. ALBA is very useful for planting about the margins of lakes and ponds, for in such positions its white leaves are very effective. It does not grow very large here, but is sometimes 100 feet high on the Continent. It is not worth planting as a timber tree here. The variety *pyramidalis*

Populus angulata at Danny Park, Sussex.

age, averaged about 60 cubic feet of timber each, and the wood had been sold at 10d. a cubic foot. At the time of my visit preparations were being made for replanting the area with the same class of tree. In some places the wood of the Poplar is not liked on account of its short life when in contact with the soil. Posts, for instance, made of the wood last but a very short time if they are not creosoted. The wood of the Poplar is, however, popular for many purposes, such as box-making, brake blocks, and colliery trucks, and is also in demand by cart and wagon builders. Large quantities of Poplar are imported to the eastern counties from N. Europe, the wood being split up for the manufacture of "chip" flower and fruit baskets, whilst Poplar wood is a favourite kind for match-making.

When planting for ornament only, habit,

less easily raised from cuttings, and is often propagated from suckers. Poplars can be raised from seed, but it is rather difficult to find the seeds amongst the large amount of cottony-looking fibre or fluff which surrounds them. When collected they may be sown in boxes and kept in a frame until the seedlings appear. When a plantation of Poplars has to be made it is wise to place the plants out whilst small or plant the cuttings where the trees are to grow. If the ground is very wet, advantage should be taken of any slight rise for the insertion of cuttings or trees, whilst it may even be wise in some cases to make little mounds upon which to start the trees. Once well rooted they will look after themselves. They withstand wind moderately well, and may be planted fairly close together for wind-breaks.

In the following selection of species, etc.,

is of close, erect habit, and can be used as a substitute for the Lombardy Poplar.

P. ANGULATA is a large-growing tree from the S.E. United States. It is peculiar by reason of its winged or sharp-angled branches. Although not very common, fine specimens are seen here and there, a notable one being in the gardens at Syon House. The accompanying illustration is of an old example of this species.

P. BALSAMIFERA is the common Balsam Poplar of N. America. It forms a handsome tree and bears long yellow catkins in spring. Its buds are sticky, and from them a pleasant odour is given off. A closely allied and equally ornamental tree is *P. trichocarpa*.

P. CANESCENS.—This, the grey Poplar of gardens, is often mistaken for *P. alba*. Here it is a more vigorous tree, growing 70 feet to 100 feet high, with a handsome

grey trunk and large, spreading head. It may be planted for ornament and also for the production of timber.

P. EUGENI is one of the hybrid Poplars, and perhaps the best of the older ones for general commercial planting. It is fast-growing, of erect habit, with a narrow head, and is largely used on the Continent as a hedgerow tree and for avenues. It originated near Metz about 1832.

P. LASIOCARPA is a new species from Central China. The leaves are each often a foot long and up to 9 inches wide, with red stalks and veins.

P. NIGRA, the common black Poplar, is sometimes found as a very large tree with a prominently burred trunk, but the black Poplars distributed from nurseries are not always the typical tree. Although it forms a large tree it is inferior to the hybrids for commercial planting. The common Lombardy Poplar is *P. nigra* var. *italica*.

P. SEROTINA, commonly called the Black Italian Poplar, is a hybrid between *P. nigra* and *P. monilifera*, and is a better tree than *P. nigra* for commercial planting. It grows rapidly and forms a fine large-headed tree. Few Poplars have been more widely planted. *P. marylandica* is another fast-growing hybrid with a wide-spreading head.

P. TREMULA (the Aspen) is a native of Europe and wild in the British Isles. It is very handsome when covered by its purplish catkins in spring. There is a weeping form of this. *P. tremuloides* is the American counterpart of *P. tremula* and an equally handsome tree. Of this there is also a pendulous variety known by the common name of Parasol de St. Julien.

The value of the various kinds of Poplar for planting in the vicinity of the sea does not appear to be fully appreciated, but they withstand sea air well and grow very fast. Those with erect branches and comparatively narrow heads might be used with success for street planting. Poplars are used for this purpose in some parts of Westcliff-on-Sea. D.

NOTES AND REPLIES.

Storm-resisting trees.—Mr. Elwes, in the *Gardeners' Chronicle*, has some remarks about the fitness for our climate of certain popular foreign trees:—

"No species has suffered so much as the common Spruce, a tree which has been most unduly praised by many foresters, but which, in my opinion, should be no longer planted as a forest tree except in very special localities. As an ornamental or shelter tree it is far less valuable than many others, because on deep soils, where it grows fast, it forms coarse, knotty, inferior timber, and on dry soil it grows slowly and soon decays at the heart. Ash, Beech, Larch, and Sycamore resist wind much better, and their timber is much more valuable. Poplars have suffered considerably, and even Scots Pine had their tops broken off by the weight of snow. Lawson and Nootka Cypress and *Thuya plicata* have come through the ordeal wonderfully well, for where their branches hold the snow they bend but rarely break, and I feel confirmed in the opinion which I have often expressed, that these three trees will eventually prove valuable for general forest planting."

The double-flowered Bird Cherry (*Prunus Padus flore-pleno*).—The common Bird Cherry is very ornamental in May, for at that time it is covered with white flowers and is a conspicuous object in many parts of the country. For gardens there are selected forms that have been given varietal names and which are even

better than the type, one of them being the double-flowered variety. It is a fast-growing tree, if anything, more vigorous than the ordinary form, and bears long racemes, each 6 inches or so in length, of semi-double, white flowers which last a week or more longer in good condition than those of *P. Padus*. Two other effective varieties which are more free-flowering than the type are *Alberti* and *Watereri*, the former producing racemes 4 inches or 5 inches long, whilst in the latter case they are up to 8 inches in length. It must not be supposed, however, that all the named varieties are superior to the type, for several of them ought never to have been named. This applies particularly to those with variegated leaves, notably *aucubifolia* and *aurea*, the variegation in both cases being poor. The variety *comutata*, too, though very attractive and earlier than the type, is not always a success, for it is a native of Manchuria; and, like several other trees from that country, it begins to grow too early here, and the young shoots and flowers are often seriously injured by late spring frosts.—D.

OUTDOOR PLANTS.

BEAUTY IN THE GARDEN.

ONE of the features of all small gardens should be the herbaceous border. Once started, with a little renewal each year, it is a source of continual pleasure. All plants in it should be grouped, as stray plants here and there give no effect. Have the border wide—6 feet or 8 feet at least—and the full length of the garden, and if possible facing south. Group the larger plants, such as the Lupins, Delphiniums, and Hollyhocks, at the back, coming down in height towards the front. Clumps of *Marguerites* are showy, and the purple of the *Stenactis* is always pretty, for filling up the various spaces which always occur. Buy some dark Snapdragons and group them together into a space occupying about a yard superficial, fill in another space with *Zinnias*, yet another space with *Nemesia*, and do not forget a nice clump of Pinks somewhere near the front of the border. It is surprising what effects can be got by quite simple means and a little trouble in a garden.

Paths are always difficult to deal with. Gravel gets kicked up and weedy, and asphalt is, of course, out of the question from an artistic point of view, but with stone flags the difficulty disappears, and immediately charm and tone are given to the garden. A narrow stone path with a Grass margin on both sides gives a delightful effect. Portland stone flags are excellent for this purpose, as they keep a bright whitish colour. It is better to keep the stones roughly in squares and oblongs of varying sizes than to go in for what is known as crazy pattern. The main lines of the garden should be kept simple. In a small garden straight lines are much better than wobbly curves, and much greater dignity is maintained. If at the end of your paved walk you can fix up a pergola so much the better. Have the up-rights of 4-inch rustic Oak posts, with 4-inch cross pieces on top and project them well over each side. Group the dwarf Roses together in a bed by themselves with a sunny aspect. Lavender between the Roses gives a very pretty effect. At the top of the path, and nearer the house, an arch in French trellis work may be erected—*i.e.*, the trellis work square with arched iron top. This should be constructed with sawntimbers and treated with a wood preservative, and at each angle of the arch a purple Clematis may be planted. Very often at the back of

a house there is a recess formed by the projection of the outbuildings. This, if possible, should be raised a step or two above the general level of the garden and form a small terrace.

GERALD McMICHAEL.

THE GLORIES OF THE SNOW.

(CHIONODOXA.)

THESE have been extremely beautiful this year, the first blooms having opened during the early part of February, reaching their highest state of perfection at the latter end of March and early April. There are several kinds which vary in colour from deep gentian-blue to the softest lavender-blue, and there are some approaching pink, while others are pure white. When first planted they are not—as a rule—so fine as in following years, when, if in good soil and left undisturbed, they not only increase in numbers but in length of stem and number of flowers. We grow them in masses in the Heath garden, intermingled with dwarf Heaths and the Sand Myrtle (*Leiophyllum buxifolium*), whose pink buds are on the point of bursting. Near by are Daffodils peeping from among the rich brown seed vessels of the Cornish Heath, which serve as a background. In the distance a brilliant group of the Scarlet Windflower comes into view. Apart from their use in grassy banks, the Snow Glories are used—three or four rows wide—as edgings to flower-beds, where they grow through some permanent edging plant which comes into prominence as the bulbs pass out of flower. In some instances they are allowed to trail out into the beds, and a pretty carpet they make to the Roses and other things above them, which as yet are scarcely awake. Others are charming, peeping out of retaining walls and from among summer-leaving Ferns. A few of the best include

CHIONODOXA LUCILLE, a beautiful species reaching nearly 1 foot in height, and bearing many flowers, which vary in colour from purple to the palest blue, with a white centre. It is a distinct and most attractive kind, which has withstood the trying weather we have lately had. Growing near is

C. LUCILLE ALBA, which was found by Mr. George Maw. It seems more free flowering than the blue, sending up several graceful spikes from each bulb, each carrying from ten to fifteen flowers, which, when first expanded, are slightly tinged with pale blue, but develop with age to the purest white. This charming form will be much sought after when better known and more plentiful. In

C. GIGANTEA, sometimes known as *C. grandiflora*, the flowers are almost twice the size of those of *C. Lucille*, the petals broader, and the whole flower of a decided colour, although the shades may vary on different plants. The colour of the type is porcelain-blue. I recently discovered a delicate rose-coloured variety among a colony of plants. This is the last of the Snow Glories to bloom with me, and therefore is valuable in extending the season.

C. SARDENSIS is perhaps the most graceful of them all, the flowers smaller than in the foregoing sorts, being of the deepest blue with a conspicuous white centre. This is the predominating colour, there being a total absence of the paler shades so frequently met with in those previously mentioned. It is a very telling flower and looks well in the mass, the bronzy foliage and flower stalks adding to its beauty.

E. MARKHAM.

Dahlias. During the week a large bed was planted with tubers of Dahlias in a dormant state. These are the stock plants from which, under the circumstances, it was decided not to propagate. Among them are some of the

Pæony-flowered section, which, if a trifle coarse, are always singled out for admiration on account of the huge size of the blooms. I have lost taste for them, although, no doubt, in a large bed such as the one in which they are planted, they are very showy and rather striking, more especially when viewed from some little distance.

NARCISSUS MRS. JAMES H. VEITCH.

DOUBTLESS one of the difficulties which beset the amateur cultivator of Daffodils to-day is what sorts to select which are suited to the ordinary methods of outdoor gardening, and reasonably cheap withal. To any such the above named, of which an illustration accompanies this

good idea of its general character. Happily, too, it is among the cheap Daffodils of to-day, and a dozen may be purchased for seven or eight shillings. The variety is of Dutch origin and is grown by the leading specialists in England. E. H. JENKINS.

Orchis mascula.—This well-known native plant makes a very pretty subject for a semi-wild part of the garden. It grows very well here in North London in a half-shady bed of a rather rich, heavy vegetable soil. It appreciates dampness, though it may often be found growing in

garden. It usually flowers in July or August, but the date of planting would determine the month of blooming. Planting can be done in May in a well-drained soil. In warmer districts April would not be too soon, while planting can also be deferred until June. The flowers are of a salmon-scarlet shade with crimson blotches at their base.—C. TURNER.

Jonquils.—The ever-increasing varieties of *Narcissi* in bloom have been augmented by the Jonquils, which now (April 23) are in hue form. Both the large-flowered and the smaller kinds are represented, and as they are sweetly-scented they are always welcomed for cutting. Jonquils, too, force well, and are equally appreciated as pot plants early in the year.—KIRK.

Limnanthes Douglasi.—This is a useful free-blooming hardy annual. Sow out-of-doors now in any good soil. It averages about 6 inches high, so should be sown in the front of the border in patches or as an edging. It can also be sown in August and September in warm districts, and treated thus it blooms much earlier.—E. T. ELLIS, *Wetwood, Ecclesall, Sheffield.*

NATIONAL AURICULA AND PRIMULA SOCIETY.

THE annual exhibition of the southern section of this society was held in the Royal Horticultural Hall on May 2nd last, the occasion marking the fortieth of its kind. As might have been expected, the exhibition was not a large one, the competition being less keen than in previous years. At the same time, it should, in fairness, be stated that the exhibits in the leading classes were particularly good, and came in for a large share of attention. The James Douglas Memorial Challenge Cup, the "Blue Riband" of the occasion, offered this year for six alpine Auriculas (amateurs), was won by Miss Lowinsky, Sunninghill, Berks. Mr. James Douglas, Great Bookham, was, as usual, a chief prize winner. Following are some of the more important exhibits:—

For twelve Auriculas dissimilar two competed, Mr. James Douglas, Edenside, Great Bookham, being a good first, having, among others, excellent examples of Harrison Weir (the best of the crimson selfs), Richard Headley (superb grey-edged variety), Rachel (white edge), Sir John Falstan (yellow), and Ringo. Messrs. Phillips and Taylor, Bracknell, Berks, were second, Mikado, Mrs. Phillips, and Acme being some of the finer sorts. These two exhibitors were in the same positions for six Auriculas distinct, Mr. Douglas showing W. Smith (green edge), the variety being awarded premier in its class, Harrison Weir, George Lightbody, Ringo, Marmion (grey edge), and Acme (white edge). For four Auriculas distinct, the before-mentioned exhibitors being ineligible to compete, Miss Lowinsky, Sunninghill, Berks, was first, her best being Acme, favourite, and Smiling Beauty; second, Mr. J. C. Allgrove, Slough, who staged George Lightbody, Favourite, and Mrs. Henwood. Mr. C. Turner, Slough, led in the class for a single specimen self with Mikado (one of the best dark varieties); Mr. Douglas following with the indispensable crimson Harrison Weir. For four show Auriculas open to amateurs only, Mr. H. W. Mason, The Hutch, Banstead, was first, having Victor, Colonel Champneys (fine grey edge), and Heather Bell (white edge).

Alpines.—The class for twenty-four alpine Auriculas, not less than twelve distinct varieties, was a considerable attraction, albeit only two collections were staged. In this, Mr. Douglas was first with an admirable lot, his set including Argus (fine red, white centre), also awarded premier, King George (good centred maroon, shaded reddish-bronze), Gold Eye (crimson and gold), Phyllis Douglas (the finest white-centred alpine known), Duke of York (red and gold), Prince of Tyre (violet-purple, pure-white centre, very handsome), Mrs. J. Douglas (purple, white centre), and Day Dream (red and gold). Messrs. Phillips and Taylor, who were second, showed the white-centred and crimson Silverwood (premier), Argus, Phyllis Douglas, Majestic, Antonio, and Miss Lowinsky (red and gold). The two exhibitors just named were in the same order for twelve Auriculas, Mr. Douglas having very fine plants of Argus, Prince of Tyre, Actæus, St. Vincent, and Firefly (glowing red and gold). For six alpine Auriculas distinct, amateurs, two competitors staged, the James Douglas Memorial Challenge Cup being awarded to Miss Lowinsky, Sunninghill, Berks, for an excellent set comprising Claude Halcro, Mrs. J. Douglas, Thetis, Phyllis Douglas, Argus, and Antonio. Mr. J. L. Gibson, Belmont, Surrey, the cup winner in 1914, showed Pilatus (First-class Certificate), Mrs. J. Douglas, Claude Halcro, Roxborough (violet, white centre), Prince of Tyre, and Argus, indispensable to any collection. Another attractive class was that for twelve fancy Auriculas. Here Mr. Douglas was alone, showing Golden Dream, Cassius (red, white centre), Cato (a particularly good yellow), Sir Edward Cassell (yellow, white centre), Sunrise (green, reddish-claret ground, and white centre) (a most remarkable combination), Kestrel (green edge), and Spectre (the nearest approach to a pure white Auricula). Mr. H. W. Mason, Banstead, was first for six alpine Auriculas and six fancy Auriculas, Prince of Tyre, Brilliant, Muriel, and Mrs. J. Douglas being best in the former, and Lady Veitch (fine red) and Great Warley (pale mauve) in the latter. In the class for six

Narcissus Mrs. James H. Veitch.

note, may be recommended without the least hesitation; not because of a special beauty or refinement exceeding all others of its class, but because of a general utility, boldness, and constitutional vigour which, combined, are not readily surpassed. It is of the yellow trumpet class, and produces a flower of great size and substance. Because of these attributes it has more than once been compared to a giant Emperor, though of a somewhat deeper yellow tone than that well-known sort usually assumes. Than this surely no greater tribute is needed, while the flowers depicted in the illustration give a

quite dry situations. It transplants quite easily when in flower, but it is necessary to dig deeply when moving it, as the tubers are some way below the surface. My plants came from a damp meadow where they were growing in thousands, and they seem quite happy in a town garden where they are mixed with Cowslips, Primroses, Bluebells, etc., making quite a pretty picture just now. The pretty spotted leaves begin to appear about December if the weather be at all mild.—N. L.

Anomatheca cruenta.—This charming little bulbous plant is well adapted for the rock

alpine Auriculas for those amateurs who have never won a first prize, Mr. F. Pain, Seven Kings, was first, having Prime Minister, Argus, Duke of York, and J. T. Bennett Poë.

Primulas.—For a group of *Primula* species and varieties on a space not exceeding 12 feet, Mr. J. C. Allgrove staged the double crimson Pompadour Primrose, also Mrs. Berkeley, Forresti, sibirica chinensis, marginata, Julia, verticillata, frondosa, and others. This exhibitor was also first for six Primulas, having Veitchi and the peculiar red-flowered tangutica among others. Mr. G. W. Miller, Wisbech, was first in each of the following classes: Twelve fancy Polyanthus, single specimen Polyanthus, twelve single Primroses, and six double Primroses (not necessarily one plant of each).

Mr. John Crook, Camberley, in a non-competitive display of Polyanthus, showed a considerable variety of his new terra-cotta strain, which represents quite a new break in this popular race of spring flowers.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM MAY 4TH.—*Rhododendrons* (in several varieties), *Azaleas* (in variety), *Cydonus* (in great variety), *Berberis* (in variety), *Pyrus alatus* (in variety), *Prunus* (in variety), *Camellias* (in several varieties), *Amelanchier coronaria*, *The Snowy Mespius* (*A. Botrydium*), *Labrador Tea* (*Ledum latifolium*), *Sand Myrtle* (*Leptophyllum buxifolium*), the *Pearl Bush* (*Exochorda*), white and yellow *Broom*, double and single *Gorse*, *Salix Britzensis*, *Daphnes* (in variety), *Lilacs*, *Evergreen Laburnum* (*Piptanthus nepalensis*), *Coronilla glauca*, *C. Emerus*, *Viburnums* (in variety), *Keria japonica* (single and double), *Japanese* and other *Cherries* (in variety), *Andromeda*, *Corylopsis* (various), *Ribes speciosum*, *Magnolias* (in variety), *Spiraea arguta*, *Laurus Miscchana*, *L. Zebelliana*, *L. nobilis*, *Arctostaphylos californica*, *A. Uva Ursi*, *Vaccinium Vitis Idæa* and its major variety, *Clematis alpina*, *Snowdrop-tree* (*Halesia tetraptera*), *Mexican Orange* (*Chorizanthe ternata*), *Heaths* (in variety), *Grevillea rosmarinifolia*, *Aubrietias*, *Windflowers* (in variety), *Saxifrages* (various), *Grape Hyacinths* (in variety), *Bluebells* (numerous), *Tulips* (in variety), *Narcissi* (in various colours), *Sandwort* (*Arenaria balearica*) *A. montana*, *Snowflakes* (in variety), *Crinus* (white, rose, and purple), *Fumitory*, *Solomon's Seal*, *Lily of the Valley*, *Tufted Pansies*, *Forget-me-not* (blue, pink, and white), *Alpine Phlox* (several kinds), *Brodæa unjora*, *Crown Imperial* (various colours), *Fritillaria Meleagris* (various), *Jonquils*, *Ranunculus amplexicaulis*, *R. spiciosus fl.-pl.*, *Ranunculus canadensis*, *Gentianas*, *Auriculas* (various), *Primulas* (in variety), *Foam-flower* (*Tiarella cordifolia*), *Achusa myosotidiflora*, *Othonnopsis chetrefolia*, *Helichrysum bellidoides*, *Veronicas*, *Omphalodes verna* and its white form, *Chrysogonum virginianum*, *Armeria Lauchiana rubra*, *Geums* (in variety), *Viola cornuta*, *V. gracilis*, *Sun Roses* (*Helianthemum*) (in variety), *Lithospermum prostratum* and its variety *Heavenly Blue*, *Potentilla alba*, *Mazus rugosus*, *Bleeding Heart* (*Diclytra spectabilis*), *Ornithogalum* (various), *Honesty* (white, rose, and purple), *Doronicum*, *Megaseas* (various), *Barrenwort*, *Calthas* (in variety), *Water Hawthorn* (*Aponogeton grandiflorum*), *Globe-flowers*, *Meconopsis sinuata latifolia*, *Woodruff* (*Asperula odorata*), *Hutchinsia alpina*, *Houstonia cœrulea*, *Cytisus Ardoini*, *Callonia grandiflora*, *Pentstemon Scouleri*, *Dryas octopetala*, *Oxalis corniculata*, *O. tropæoides*, the *Green Columbine* (*Aquilegia viridis*), *Linaria aquitiloba*, *L. Cymbalaria alba*, *Camassia Cusicki*, *Draba gigas*, *Oxalis enneaphylla*.

WORK OF THE WEEK.—A further planting of Violets (*Ascania* and *J. Raddenbury*) has been made to furnish a narrow border in the full sun, while in the shade and on the ledge of a retaining wall the variety *Baron Rothschild* was used. The weather being favourable, further sowings of annuals have been made. *Pentstemons* have been planted out, one large bed being devoted to them entirely, with the exception of permanent tripods of *Clematis*, which stand among them. The varieties *Newbury Gem* and *Southgate Gem* were used, and the same kinds have been planted as a groundwork to *Henry's Lily*. *Felicia abyssinica* has been put out as an edging to a large bed of mixed Lilies. *Cherry Pie*, raised from seed, has been potted up and given a light position near the glass in a warm house. The removal of plants to cold frames is now of daily occurrence, and these will be thoroughly hardened before planting out. Tubs and vases containing large specimens now receive attention, but this must be carefully done, as extremes of temperature will ruin them for the season. Seedlings of *Delphinium*, *Erigeron strigosus*, *Cynoglossum amabile*, *Aethioppus pulcherrima*, *Lupinus*, hardy *Geraniums*, and *Sweet Williams* have been pricked out a few inches apart in the nursery beds. The final staking of *Sweet Peas* is now being attended to. The stakes usually stand from 8 feet to 10 feet out of the ground. *Carnations* on the layering ground have been cleaned and the soil, which had become hard and caked, well loosened up among the plants. A number of *Salvia patens* and *Veronica Lyalli* has been planted in the flower garden, the latter as an edging. The *Lily tank*, which is now gay with the *Pontic* and *Tyermann's Kingcups*, and

Water Hawthorn, has been cleaned, as the Lilies are now on the move. A sunny bed has been planted with the *Chilian Bellflower* (*Nolana atriplicifolia*), and to break up any flat appearance small groups of *Canary Creeper* (*Tropæolum aduncum*) have been introduced at intervals, and will be supported on small *Pea-boughs*. A few *Perpetual-flowering Carnations* have been planted out in a specially prepared bed edged with *Shamrock Pea*, which has also been used to drape a low retaining wall in front of a bed of *Crinums*.
Sussex. E. M.

SOUTHERN COUNTIES.

Callas.—As a rule, these, after being hardened off, are stood in full sun in order that the crowns may become thoroughly ripened. Attention in regard to watering for some time after the plants are stood outside is, of course, necessary. To obviate this they are this season being planted out in a sunny spot, where they will remain until it is seen that the crowns are about to start growing. They will then be lifted and potted. The crowns of *Calla Eliottiana* have this season been purposely retarded, but as no advantage is to be gained by carrying this any further, they will now be potted in a mixture of loam, peat, a little leaf-mould and sand, and placed in a vinery until growth has sufficiently advanced to warrant their being placed in a warm greenhouse. Three corms are placed in an 8-inch pot.

Chrysanthemums.—These have been shifted on into 5-inch and 6-inch pots and stood in frames on a hard base of ashes and near a water-tank. When the roots begin to push through the new compost the plants will be freely aired and stopped as necessary to ensure a bushy habit of growth. In the meantime the pots into which they will finally be shifted will, as opportunity offers, be washed and crocked, so that when the time arrives the work can be carried out expeditiously. For the same reason the preparation of the compost, with the exception of adding the artificial manure, will be seen to.

Cytisus racemosus.—This is just passing out of bloom. To keep the plants dwarf and bushy they need to be cut back fairly hard every season. This leads to a quantity of new growth, which if properly ripened never fails to flower abundantly. A vinery is a good place in which to give them a start after having been cut back, the moisture and syringing greatly facilitating matters. As soon as they have broken, any repotting that is necessary should be done, and as soon as they recover from root disturbance less warmth is needed. When growth is complete they are moved outdoors and plunged to the rims of the pots in a bed of ashes in company with *Azaleas*.

Cyclamens.—Plants which have been flowering during the past winter and until recently have been moved into a cold pit to undergo the remaining period of rest, so that they can be shaken out, repotted, and started again not later than the middle of June. The young plants are making satisfactory growth, and require little or no artificial heat now that warmer weather has set in. Shade—not too dense—is required to protect the young foliage from the direct sunlight. A gentle spraying three or four times daily keeps them growing freely. Thrips and green-fly have to be watched for, and the house vaporised if signs of either or both are detected. As a rule, the former does not prove troublesome if the ashes on which the pots are stood are kept moist. The plants will very shortly be ready for transferring to the pots—6-inch and 7-inch—in which they are to bloom, the more robust-growing varieties being put into the latter-sized pot.

Perpetual Carnations.—These have been gone through again, and a few of the oldest and least desirable examples have been dispensed with. The general stock has been tied and dressed with manure and rearranged. To prevent an outbreak of red-spider the paths and beds are damped occasionally on hot days. The roof has been "stippled" with a green mixture similar in tone to that obtained by the use of the well-known "Summer Cloud." In the daytime all the air possible is admitted both at the top and sides of the house. *Malmaison Carnations* have been finally tied, and a dressing of *Carnation manure* applied to the surface of the soil and worked in with a pointed stick. It is now requisite to use the blinds during the hottest part of the day and afford the fullest ventilation. A certain quantity of clarified soot-water is put now and again into the tank from which water is obtained to supply the needs of the plants. The beneficial effects of this are reflected in the bold-looking, dark-green foliage and vigorous appearance of the plants.

Sweet-scented Tobacco.—This being in great demand for planting in borders or places where space can be found for a few plants on account of the delicate perfume emitted by them during the evening, a large number of plants has been pricked off into boxes, whence they will be transferred the last week in May to where they are to flower. A good number of *Sander's* variety will be pricked off at the same time.

Late Broccoli.—As a rule, the seed of late Broccoli is sown far too early, the result being that the heads turn in before the maincrop sorts are over and cause a glut. For the

south the second and third weeks in May are quite soon enough to sow. The plants can then be depended on to produce their curds in their proper season and cover the period elapsing between that of the last of the maincrop varieties and the commencement of the Cauliflower season. Unless closely watched and the young plants occasionally dressed with a mixture of soot and lime after having been sprinkled with water, they are more liable to fall a prey to the ravages of the Turnip-beetle than is the case with earlier sowings. Keeping the soil in a moist state tends in a great measure to ward off attack. The seed will be sown in drills drawn 1 foot apart on a piece of well-matured ground, the whole plot being securely netted afterwards as a precaution against the attacks of small birds.

Late Savoys and Coleworts.—These succeed best when sown and raised under similar conditions and at the same time as the preceding. Another and final sowing of Coleworts, when a heavy demand has to be met, should be made the second week in June.

Broad Beans.—The last sowing of these will be made on firm ground, the variety selected being the *Green Windsor*.

Peas.—Besides sowing again for succession, much time has to be devoted to the moulting and staking of those previously sown. If growth is too far advanced before these matters are attended to the haulm never clings to the sticks properly afterwards. The usual care bestowed on the staking of Peas is this season out of the question, and so long as the stakes can be placed in position for the support of the plants, this has to suffice.

Pricking-off, etc.—Further batches of *Celery* have been pricked off, also *Parsley*, on two long and narrow borders. *New Zealand Spinach* has also been sown in pots and placed in warmth to germinate. Early Turnips have been thinned to 9 inches apart, and afterwards damped and dusted over with soot and lime.

Strawberries.—The summer mulch of straw litter for keeping the fruit clean will at once be placed between the rows and around the plants, as this can be done far more conveniently and expeditiously now than when growth becomes further advanced. The hoe will be run through the surface first, both to aerate it and to get rid of weeds just springing up. Whatever manurial properties there may be remaining in the mulch, which will be of old stable litter, will, when rain falls and washes it out, be at once absorbed by the soil. On soils which are apt to be infested with slugs the surface should be dusted with soot and lime before the mulch is put on between the rows.

Peaches and Nectarines.—Disbudding now demands attention. The upper portions of the trees are dealt with first and the inner parts last. Too many growths must not be removed at one time, as the young fruits yet require some amount of shelter as well as support from a free flow of sap. When dull, with the wind blowing from an easterly direction, disbudding is for the time suspended. A. W.

MIDLAND COUNTIES.

Grapes on Vines started at the end of December are now colouring, and require a drier atmosphere. Gradually decrease the moisture, with a freer circulation of warm air, leaving the top ventilators open a little at night. Always guard against sudden changes of temperature, as these cause moisture to condense on the berries, which is detrimental to the bloom. The laterals may now be allowed freer extension until the Grapes are cut. The border, having been well watered and mulched, these Vines will not require any water until the Grapes are cut. In the case of succession vineries, damp them down as often as the dryness of the atmosphere demands. On dull days once will be sufficient, while on bright days it may be done four times. Ventilate freely so as to keep the leaves firm and healthy, beginning early in the morning to prevent scalding of the foliage, and increasing it as the temperature rises. As it declines in the afternoon reduce, and close when it does not exceed 85 degs. But little fire-heat will be required, except at night and on dull days. Frequently go over the Vines and remove all laterals. For Vines in flower, keep more warmth in the hot-water pipes during the day, except when the weather is very hot. About noon go over them, giving the rods a few sharp raps with the hand to distribute the pollen, and in the case of shy-setting varieties fertilise with a rabbit's tail. Do not stop the laterals during the time the Vines are in flower. Damp down but once, and on fine days only. Early in the afternoon is the best time to do it.

Strawberries in open quarters are showing splendid trusses this season. A mulch will shortly be applied to keep the fruits clear of the soil. As there is a shortage of straw this year I shall use long Grass mown carefully and laid straight. The sun soon dries it, being cut early, there is no need to scatter. Garden netting, which is used to preserve ripe Strawberries and other fruits from the birds, may be used with advantage to protect the open blossoms from the effects of late frosts. Place a few forked sticks into the ground at short intervals in breadths of Strawberry plants to be thus protected, so as to keep the netting clear of the blossoms. If the netting be doubled or trebled in thickness it will neces-

sarily be more effective. Maiden Strawberry plants from which the current year's supply of runners is to be obtained will be divested of their flowers.

Peach-trees on a south wall have set a very heavy crop of fruit, and severe thinning is necessary. A knowledge of the size to which the fruits of the several varieties attain under good cultivation is desirable on the part of those entrusted with the thinning. Fruits of such varieties as Alexander, Hale's Early, Amsden June, Bellegarde, and Stirling Castle being of medium size may be left a couple of inches closer on the trees than fruits of Royal George, Violette Hative, and Prince of Wales, whilst such large-growing varieties as Exquisite, Princess of Wales, Sea Eagle, and Late Admirable should be given still more space. Therefore, thin out the fruits upon the varieties named to 5 inches, 6 inches, and 7 inches apart, according to size, reducing the numbers by one-half a few weeks later, leaving, as a matter of course, the most even-sized and best-placed fruits to form the crop on each tree.

Spring-flowering plants.—Where these have to be cleared from the beds to make room for the summer occupants the lifting and removal to the reserve garden must now be taken in hand. Double Primroses must be increased by division, and the divided pieces should be planted out in a very moist piece of ground, choosing also a shaded site not overhung by trees. A north-wall border is an excellent position for them. For the single-flowered types of "Bunch Primroses, which bloom so freely, no method of division will equal the stock raised annually from seed. The yellow Alyssum (*A. saxatile*), which is regarded as a somewhat "miffy" plant in some gardens, and which certainly has a tendency to die out if allowed to become old, may be readily renewed by slips taken off and dibbled into sandy soil. The white Arabis ought also to be kept up by propagating young stock yearly for all purposes in which neatness of growth is necessary. When clothing a wall or rockery, the plants may be allowed to get old, and they increase in effectiveness each year; but for bedding, young stock is desirable each year. As the flower-beds are cleared of their spring flowers they should be liberally manured and deeply dug. This is frequently neglected, though to do so is a great mistake. The plants for beds and borders should now be gradually hardened off and made ready for planting out as soon as all fear of frost is over.

Annuals.—Many of those first sown now require thinning. In view of the unusual number of slugs and snails which are about, this must be done gradually or there will probably be blanks. All plants should finally be allowed ample room for development, and more seed may be sown now for future displays. The annuals raised in heat and pricked off into frames are now sufficiently hardened off to be transferred to their flowering quarters. If this can be done during dull or showery weather the check of removal will be slight.

Celery.—Plants from the earliest sowing are now ready for planting into the trenches prepared for them some weeks ago. At the first favourable opportunity they will be lifted with as much soil adhering to the roots as possible, and planted in double lines from 10 inches to 15 inches apart, according to the variety. The soil about the plants should be made firm, and a dusting of soot applied during the evening or early in the morning once a week. Celery should never be allowed to suffer from drought. Further trenches are prepared for later plants as opportunity offers.

Celeriac, or Turnip-rooted Celery, requires a long season of growth, an abundance of moisture, and rich soil. Strong plants should be put out at the present time on flat beds or borders that have been deeply trenched and heavily manured. Allow a distance of 2 feet between the rows and 18 inches between each plant. During the season of growth it is difficult to over-water this crop, and if possible liquid-manure should be given frequently. Dust the foliage with soot occasionally, as in the case of Celery.

Carrots as soon as large enough will be thinned out to 3 inches apart, and a dressing of soot and wood-ashes applied. Another liberal sowing of the stump-rooted varieties will be made during this month.

Turnips should be thinned whilst the plants are quite small, the surface-soil frequently stirred, and a dusting of soot applied at intervals of a fortnight. Small sowings should be made at frequent intervals to maintain a supply. Suitable varieties for sowing at this season include Orange Jelly, Snowball, and Red Globe.

Onions.—When Onion seed has matured properly it comes up, as ordinarily sown, too thickly, rendering a good deal of thinning necessary. When thinning, let all weeds be pulled up carefully, so as not to disturb the Onion plants, and in dry weather keep the Dutch hoe at work between the rows.

Broad Beans.—The last sowing will now be made, choosing a cool position. As soon as sufficient pods are set, the plants should be topped or they are sure to suffer from the attacks of blight.

Chicory sown in April is now ready for thinning to 10 inches apart. Frequent dustings of soot and lime are necessary as soon as the plants appear above ground, slugs being

particularly fond of this plant. Another sowing will now be made on deep, rich soil in rows 18 inches apart.

Brassicas.—Where seeds have been sown thickly it will be prudent to lift and prick out in nursery beds Brussels Sprouts, Broccoli, Kales, and Savoys in variety before they get drawn. A distance of 4 inches apart will be suitable, provided permanent planting is done in June and early in July. A sowing of walcheren and Self-protecting and of late varieties of Broccoli will now be made. The first two will prove useful late in the year, and the latter will prolong the supply in early summer next year.

Tomato plants should be hardened off as soon as possible and be planted out in sunny, sheltered positions by the end of the month.

F. W. GALLOP.

SCOTLAND.

Walks and paths.—The regravelling of garden walks will shortly be attended to. The annual wear and tear are more obvious in some parts than in others, but all over a freshening up with new material will be given as time permits. Being within easy distance of the beach, plenty of gravel of a suitable grade can be secured merely at the labour of sifting and carting. It is rather of a flat than a round grade, and makes very useful stuff for the purpose. Meantime, the garden walks, etc., have been dressed with weed-killer. There is a prejudice against weed-killer in some places, but its use undoubtedly saves a great amount of labour during summer and autumn. The strength of the majority of weed-killers is, of course, variable. The proportion recommended is usually one part of liquid to fifty of water; but I find equally good results from the use of 1 gallon of weed-killer to 70 gallons of water. Care, of course, has to be taken in the immediate vicinity of Box edges or of Grass verges. The best time at which to apply weed-killer is when the walks or paths are damp, but not wet, and when there is a likelihood of a period of settled weather.

Bare patches under trees have been sown over with Grass seed. Returfing has been given up as the herbage soon died off during summer, and although annual sowing has to be done it produces a green covering which lasts in fairly good order until the falling leaves cover it. Seeds from the hayloft are quite satisfactory for this purpose.

Potting and repotting.—At this time growth is rapid, and plants intended to make large specimens must never be permitted to become pot-bound before receiving a shift. Thus, Zonal Pelargoniums, Petunias, Begonias, and Fuchsias have received their final move, and when the roots fully occupy the soil they will be assisted either by chemical stimulants, by liquid-manure, or by soot-water. The last might be used to a much greater extent, for nearly every plant responds to its use. One exception is made in the subjects mentioned. Begonias, I think, are better without the use of chemical aid, for I have frequently noticed that tubers which had been highly fed are very liable to rot when stored. Small plants, including such things as Libonia floribunda, Primula obconica, Abutilons, Aloysia citriodora, Begonia Rex, Verbena radicans, and Campanulas of kinds, have had a shift commensurate with their needs.

Cinerarias, chiefly *C. stellata*, were pricked off during the week. For this purpose 10-inch pans are used, and twelve seedlings are allowed to each pan. This permits the plants to attain to some size before potting, and the disturbance, I think, is less than when frequent shifting is practised. Last year the plants were put straight into their flowering pots from the pans, and the success of the experiment was undeniable. The same course will be followed during the present season. The pots are plunged to the rims in cold-frames, and while at first very careful watering is necessary, yet this method results in a considerable saving of time. As the season advances the sashes are removed, and the plants are treated exactly as if they were planted out until the approach of early frosts.

Cucumbers.—Seeds have been sown to provide plants for putting out in pits at present occupied by Celery. The Celery will be fit to go out by the end of the month, and a mound of good material in the centre of each pit will be provided for the Cucumbers. These bear freely during summer and early autumn without the aid of fire-heat. The Cucumbers will be the third tenants of the pit since February of this year. Firstly, they were utilised for raising Onions. These, when put out, were succeeded by Celery, which, in turn, will be followed by Cucumbers.

Wallflowers.—Seeds of the various Wallflowers were sown during the week. As a rule, Wallflowers are sown too early. No doubt, the plants furnish better at planting-time, but the check is correspondingly greater. Smaller plants take hold more quickly, and, given favourable weather, soon make up the leeway. While the double Wallflowers are, in their way, showy, yet they have been discarded during the present sowing, reliance being placed solely on some of the older single sorts, such as Blood Red, Belvoir Castle, Harbinger, and Vulcan.

Pentstemons.—Several long beds were planted with Pentstemons of the Gem varieties. These are useful, enduring, and showy, while their wintering does not entail any out-

lay in respect of fuel. The plants, having been grown coolly, are thrifty and bushy, and soon fill up their allotted space. Good sorts for such beds may be found in Newbury Gem and Southgate Gem.

Gladioli.—A final planting of dormant corms has been made. A large oval bed, 12 feet by 24 feet, was planted thickly, the corms being put at intervals of 9 inches. Afterwards the bed was broadcasted with *Eschscholtzia californica* to correspond with a similar bed planted some time ago.

Sweet Peas and hardy Chrysanthemums.—The planting of these two popular and useful subjects was completed during the week. The Peas are grown in good groups, and after the supports of wire-netting were put in position shallow trenches were made in which the plants were placed. As growth progresses the soil will be returned, and will help to keep the roots cool. A further advantage of planting in such trenches is that, should it be necessary, watering is much more easily done. The Chrysanthemums were put out in lines where possible, and in groups through the borders. After planting, stakes were at once put in.

Hardening off.—As there is yet some little risk of frost, especially in the early mornings, the boxes and pans are so arranged that they can be easily protected if necessary.

Under glass the work now tends to become routine for a time. The usual attention to watering, syringing, and ventilation is given, and with a return of summer-like weather much less firing suffices to keep things in good order. In the case of plant-houses, with the exception of the stove, the fires have been stopped, except on an occasional dull day or an exceptionally cold night. It is considered advisable, however, to keep a moderate heat in the pipes of the stove for a short time yet.

Wall trees.—With the exception of Apples, wall trees are in full bloom. As previously indicated, stone fruit is very promising. In the case of Peaches and Nectarines a satisfactory set has been secured, and Plums appear to be setting quite freely. The absence of severe frosts up till now is all in their favour; and if in some instances the show of bloom upon Pears is not quite so encouraging, yet, all over, there is an average promise. Hand fertilisation is always done in the case of Pears on walls.

Vegetable garden.—Maincrop Carrots were sown, and full supplies of Beet were put in. The sorts preferred are Dell's Crimson and Nutting's Dwarf. Good breadths of Cauliflowers Early Erfurt and Walcheren, Red Dutch Cabbage for pickling, Early York Cabbage, Hearting Kale, and a few lines of Brussels Sprouts were put out for early autumn use. The soil was in excellent condition, and the plants already appear to have taken hold. More Turnips (White Stone) were sown, and further supplies of Spinach were got in. Early Cabbages were a little later than usual in being available, but they are now plentiful, and Asparagus is being cut as required.

Kirkcudbright.

W. MCGUFFOG.

OBITUARY.

JOHN WRIGHT.

IT is with regret we have to record the death, at the age of 80, of Mr. John Wright, who was for many years editor of the *Journal of Horticulture*. In 1888 Mr. Wright was awarded the gold medal offered by the Fruiterers' Company for his essay on fruit culture. He was also awarded a gold medal offered by Dr. Hogg for a paper on fruit culture, while the Veitch Memorial Medal was presented to him in 1894. In addition to his duties in connection with journalism he found time to produce a series of gardening guides, including the Fruit Growers', Flower Growers', and Vegetable Growers' Guides. He was for many years a member of the Fruit and Vegetable Committee of the Royal Horticultural Society, and also took a great interest in the United Horticultural Benefit and Provident Society. His work on behalf of school gardening was regarded by many people as his greatest contribution to horticulture.

MR. DAVID PRIOR.

WE regret to announce the death, at the age of 84, on Tuesday, May 2nd, of Mr. David Prior, founder of the well-known Rose-growing firm, Colchester. He first started as a florist and nurseryman at Myland, and in later years, assisted by his son, he specialised in the culture of Roses, winning many prizes, including the late King Edward's Challenge Cup, which the firm won outright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Cinerarias after flowering (Beginner).—In a general sense, Cinerarias after flowering may be thrown away, and be replaced by other seedlings raised annually; but, in the case of a very choice variety, which it may be desirable to propagate from, the bloom-stalks should be cut down nearly close to the soil, and the plants should be placed in a cool, moist frame, where they will soon send up suckers. These will strike root freely if potted off into small pots in a mixture of sandy loam and leaf-mould.

Mignonette in pots (A. L. S.).—Perhaps the best way to grow this in pots is to sow a dozen good seeds in a 5-inch or 6-inch pot. Reduce the number of plants to four when they have grown somewhat. When the seeds are sown, space ought to be left for a dressing of rich soil on the surface before the plants come into flower. If they are grown under glass see that they are placed in a light position, and the nearer the glass the better, as a close, compact growth is best, and this will not be obtained if the plants are shaded in any way or crowded up.

Gloxinias (G.).—These are very easy to grow when the conditions are suitable. Until the plants come into flower a moist position in a warm house or pit is the best. They do not like syringing, and they should be shaded from the sun when bright. A light, rich soil suits them well. Use peat and leaf-mould in equal parts, and a few rough bits of old turf, with plenty of sand to make it porous, and a few scraps of charcoal to keep it open. The pots must be well drained, as the plants will require liberal supplies of water when in full growth. A night temperature of 60 degs. will suffice, though they will bear more heat, and have been well grown in less.

Treatment of Pelargoniums after flowering (H.).—Large-flowered Pelargoniums, when they have done blooming, should be set out-of-doors for a time to harden the growth, and a very moderate supply of water should be given at the same time. When the wood has become brown and hard they may be cut down to about three or four eyes, then place them in a well-ventilated frame. Do not give much water, but syringe them twice daily to induce them to break freely. When this is the case they should be shaken out of the soil and have the roots shortened back a little, and be repotted in a sandy, loamy compost in pots a size smaller than they flowered in. Replace in

the frame, and shade a little, and keep rather close until active growth sets in, then ventilate freely. Later in the season pot on into larger pots, and give ordinary greenhouse treatment.

Symphandra pendula (Inquirer).—This is a showy perennial Campanula-like plant, with branched pendulous stems and large, cream-coloured bell-flowers. It is quite hardy, and rarely more than 1 foot high. Your best plan will be to raise it from seed, sowing this now, and growing on the plants until the early autumn, when they may be put into their permanent position. It is somewhat short-lived, and it is always advisable to have young stock to fall back on. Seeds can be obtained from Messrs. Thompson and Morgan, Ipswich.

Azaleas after flowering (L.).—As soon as the flowers fade, pick all the seed pods off at once, and if the plants need it, shift into a size larger pots, using good peat and some sharp silver sand. The pots should be well drained, and the soil made very firm around the roots. They should then be placed in a warm, moist growing temperature, be frequently syringed, and shaded from very bright sunshine. As the growth advances, inure to more air and sunlight, and when the buds are well plumped up at the points of the shoots, say by the month of August, they may be placed out-of-doors for a time, and in September they should be housed again.

FRUIT.

Treatment of Melons (Inquirer).—The main shoots of Melons should be stopped when they are within 6 inches or 8 inches of the sides of the frame. The laterals which spring out all along these main shoots should be stopped one leaf beyond the fruits. After the crop is set and swelling rub off all lateral growth when it shows, permitting nothing to shade or crowd the main leaves. As regards temperature, the Melon likes warmth both at the roots and also in the atmosphere. In summer a good deal may be done by early closing, shutting up the sunshine in the frame; but a little ventilation should be given early in the morning. Perhaps the most important thing in Melon culture is to have a firm bed of good, sound loam for the roots, so that the growth may be robust and at the same time firm. When Melons are planted in light rich soil it will be difficult to keep them right.

SHORT REPLIES.

Enquirer.—The fruits of all the crosses between the Raspberry and Blackberry are liable to go mouldy in wet weather.—A. T.—Short of ploughing and cleaning the field, we

know of no remedy, and this may not be possible, as the pasture, in spite of the Dandelions, may be good. The only way is to see to it that the plants do not flower and ripen their seeds.

NAMES OF PLANTS AND FRUITS.

Names of plants.—F. T.—1, Anemone blanda; 2, Doronicum caucasicum; 3, Anemone coronaria var.; 4, Anemone nemorosa.—M. L.—1, Brodiaea uniflora; 2, Anemone stellata; 3, Polemonium coraeum variegatum; 4, Muscari conicum.—W. H.—1, Habrothamnus elegans; 2, Cyperus alternifolius; 3, Streptosolen Jamesoni; 4, Clivia miniata.—Q. M.—1, Fritillaria Meleagris var.; 2, The Pasque-flower (Anemone Pulsatilla); 3, Polemonium coraeum; 4, Ornithogalum nutans.—S. H.—1, The Bridal Wreath (Francoa ramosa); 2, Arabis alba variegata; 3, Epimedium alpinum; 4, Anemone fulgens.—D. T.—1, Libonia floribunda; 2, Scilla sibirica; 3, Doronicum caucasicum; 4, Grape Hyacinth (Muscari botryoides).—T.—1, Anemone nemorosa; 2, Amelanchier Botryapium; 3, Kerria japonica fl.-pl.; 4, Choisy ternata.—A. G.—1, Lithospermum prostratum; 2, Caltha palustris; 3, Pyrus Malus floribunda; 4, Ribes aureum.—F. D.—1, Berberis Darwini; 2, Kerria japonica fl.-pl.; 3, Bird Cherry (Prunus Padus); 4, Doronicum austriacum.—E. C.—Brodiaea uniflora (syn. Tritelia uniflora).

BUSINESS NOTE.

There are times when labour has to be economically used, and when, nevertheless, good results are wanted in all gardens. Any deficiency of labour has to be made up by scientific methods. It is under these circumstances that many gardeners will be glad to be reminded of the excellent labour-saving preparations of Messrs. Tomlinson and Hayward, of Lincoln. We refer particularly to their Eureka lawn sand, so valuable for destroying objectionable growths on lawns, to their Eureka weed-killer, for clearing paths, and to their various sprays, insecticides, soil fumers, and sundries. It would be well to send a note to them asking for full particulars.

I peg a Union Jack on my clothes line every wash-day! In other words, I use the purest and best BRITISH SOAP.

SUNLIGHT SOAP

upholds our national tradition for Quality and Efficiency. It is made from the best materials in the world—by the best labour in the world—for the cleanest homes in the world. Like every typical British Manufacture IT WILL STAND EVERY TEST whether practical or analytical. So be loyal to your country! Use Sunlight Soap and peg a Union Jack on your clothes line every wash-day.

NEGLECTED ORCHARD BEAUTY.

ONE should not need to go to the Weald of Kent, the valley of the Seine, the Carse o' Gowrie, or to Worcestershire in order to see the orchard beauty which is so conspicuous in those parts where they grow the trees best. There are vast areas of the United Kingdom quite bare of orchard beauty for no reason, because this orchard beauty is given to us by trees that are quite hardy, and there is hardly any soil in the kingdom which will not grow them. If we look at most of Ireland, we see it quite bare of orchard beauty, though it has as fine a soil as one could wish for fruit-trees, even Cherries and Plums that will not grow well in heavy clays.

The beauty seen in orchards where fruit-trees are grown most of all is very often that of one tree only—it may be Cherry, or Plum, or Apple—but the country gentleman with excellent land for the purpose may have a varied orchard, and, therefore, one much more delightful than an orchard devoted to one kind of tree. This glorious beauty is greater than that which the more favoured southern people possess in their Figs and their Vines, except, perhaps, in Normandy, where lovely pictures of cider orchards in flower or fruit may be seen. Our country for the most part, except the very mountainous, is well fitted for giving us this orchard beauty, which is so great that it is worth having for itself, but there is also the inducement that the lovely trees bear precious fruit. The Pear, for example, is naturally a noble tree, and very often in the great gardens of the country one never sees it grown as a standard as it deserves to be. There are excellent hardy varieties of Pears that might come into every orchard, but, unfortunately, the Pear has been spoiled very much by the constant preaching of the small form and the over-pruned bush, which is often a sad failure; also by grafting on the Quince, whether that suits the variety of Pear or not. Thousands of Pears are grafted on the Quince which can never grow well on that stock, as the best Pear growers will tell us. For the orchard this noble tree should always be grown on the natural stock, which is the wild Pear. Even as it is grown now, what a beautiful tree it is in flower. It seems to do best on the special soils of Kent and Worcestershire, but there is no need to confine it to those counties, as Irish and good Scottish soils will grow it admirably. Another badly neglected orchard tree is

the Cider Apple. I was so much struck with the beauty of a cider orchard in Normandy that I planted one, getting my trees from that country, there being no nursery here that I knew where I could get good strong trees. The result is marvellous with the beauty of the flowers in spring and the beauty of the fruit in the autumn. The trees require no attention, and cattle graze among them, no harm coming from it. The manufacture of cider as it is made in Normandy deserves our attention. English cider is so often rough and over-acid that any way of improving it is worth considering.

The varied orchard could be planted on a piece of rough ground which one cannot plough or garden, and might be made the most beautiful feature of a country place, where even things of less importance as food, such as the Medlar and the Quince, might have their place. The main thing should be the Apple in the best and noblest forms, such as the Blenheim and the Bramley. — W. R.

NOTES OF THE WEEK.

Hesperis humilis.—A soft purple, dwarf, wild Stock from Sir Frank Crisp. It seems worth growing as a rock plant. On some heavy soils double stocks are so poor that I often think the wild single stocks better worth a place.—W.

Tufted Pansy Maggie Mott.—At present (May 11th) both on old and on young plants the display of bloom is lavish, and the soft lavender-blue is beautiful. Although, perhaps, a trifle more straggling in habit than many others, I consider Maggie Mott the best all-round variety in cultivation—certainly, at all events, in its particular colour.—W. McG.

Roses in south-west Scotland.—The past season has taken its toll of the Roses in this district, especially in the case of those planted in spring. A larger proportion than usual of plants has been killed. This is not surprising in view of the severe weather in late winter, following upon a mild January, when many plants had made a good deal of growth.—Ess.

The Blood-root (*Sanguinaria canadensis*).—This does extremely well in the rich alluvial soil of the garden of Mr. E. A. Hornel, Broughton House, Kirkcudbright, and several fine clumps were in bloom the other day. Among them is the variety called multipetala, which has narrower, but more numerous petals. It is an in-

teresting variety, and quite pretty when seen in a good clump as at Broughton House. I prefer the large-flowered *S. canadensis grandiflora*, of which there are a good many clumps in the same garden. *S. canadensis* is quite happy in the full sun.—S. ARNOTT.

Iberis Little Gem.—Those who have small rock gardens may well be reminded of Candytuft Little Gem, which is well named, and one of the prettiest of its class. In May this dwarf trailing plant is covered with numerous heads of white flowers. This Candytuft appears to do as well in a northern exposure as in a warmer one, and does not seem to resent the small amount of sunshine it receives in some places.—S. ARNOTT.

A lovely blue Poppy (*Meconopsis sinuata latifolia*).—The most fascinating thing I have in mid-May is a very beautiful satiny blue Poppy of the Himalayan region. It came, I think, to me from Sir Herbert Maxwell. It is a dwarf plant as I have it on the north side of a low wall, with lots of buds coming at the base. It is much dwarfer than the kinds of *Meconopsis* I have had before. I have it in various sizes. It is a biennial and easily raised from seed, and so far is the most beautiful of its race, especially for the rock garden.—W.

The purple Aspen (*Populus tremula purpurea*).—The Aspen is a pretty, though neglected, native tree, delighting in moist situations, where it grows rapidly when once established. The variety mentioned above is a most desirable tree with attractive purple leaves, each from 2 inches to 3 inches across, and borne on shining purple stalks, while the newly-made wood is of the same colour. The trunk and old wood of this tree are almost white, and glistening in the sunshine show up the purple foliage to great advantage, especially on young trees. It is a rapid grower and promises to become a handsome tree. I notice self-sown seedlings appearing in the vicinity of a vigorous young specimen.—E. M.

Narcissi in Scotland.—I notice that Mr. Arnott refers in a recent issue to the lateness of Narcissi in the south-west of Scotland. Locality must account for that, because here all the varieties, and they are many, were slightly in advance of the usual time of flowering. At the present date (May 11th) there are three plants in bloom which I usually expect during the last week of the month. These are the

Poet's Narciss, Lily of the Valley, and Tulipa Gesneriana. The older Tulipa fulgens is also showing colour quite a fortnight in advance of the normal date. Of course, as Mr. Arnott knows, we are specially favoured in the way of climate and position, and these factors, no doubt, have much to do with our earlier display. I may add, however, that the weather since the opening of May has been cold, inclement, and generally unfavourable.—W. McG., *Balmae, Kirkcudbright.*

Abutilon vitifolium.—This deserves all that has been said for it on page 239. It is too tender for cold, exposed gardens, save in many parts of Ireland and the southern counties of England, and it is interesting to know that it thrives in Northamptonshire. There are a few gardens in the south-west of Scotland where it is quite hardy. The white-flowered variety, *A. vitifolium album*, is not, in my opinion, so pretty as the lavender-coloured one.—S. ARNOTT.

Clianthus puniceus in Sussex.—A friend gave me plants of this, assuring me of its thriving in the forest district, but my plant was killed by a sudden cold after a long mild time. Then comes in Mr. Gerald Loder in mid-May with a fine raceme of the flowers. I thought at first it was from a greenhouse, but it came from a plant on the open wall, so with care, and in not too low ground, this fine plant may be grown in Sussex. It is grown with great success near the coast in Ireland and the west coast of Scotland.—W.

Black Cottonwood (*Populus trichocarpa*).—Having had to deal with a quantity of young trees of this during the past winter the delicious fragrance of their dormant buds was very noticeable. The buds on examination were found to be coated with balsamic gum, of such sweetness as to leave its perfume on one's hands and clothes for many hours. Quite recently, too, while walking in the evening near the fringe of woodland, I came to a spot where the air seemed full of Daphne-like odour, and a little searching revealed the presence of a few young specimens of this distinct and fragrant tree just bursting into leaf. It is a very pretty tree in leaf, and might, except for colour, easily be mistaken for a large Eucalyptus.—E. M.

Corokia cotoneaster.—An odd-looking and charming little tangle of star-like yellow flowers and small spoon-shaped leaves. Clearly from another land, as it is so distinct from European or American plants. I now regret neglecting it as a "botanical plant," whereas it is pretty. It is a native of the mountains of New Zealand. From Sir Frank Crisp. At Nymans (Sussex) I was surprised to see this, in the Heath garden, a tall bush 6 feet or more high and starred all over with yellow flowers. It was away from a wall or any protection. Evidently it is a very interesting addition. The situation is 500 feet above the sea, but is not otherwise favourable, so that we can count on it for making a very interesting bush over a very large area of the land. The New Zealand plants, as shown by Mr. Messel's experiments, are clearly well worth looking after.—W.

Berberis stenophylla.—Of all hardy trees and shrubs, this Evergreen Barberry is probably the most generally useful, and certainly one of the most beautiful. It forms a large, shapely bush without pruning. A hybrid between *B. Darwini* and *B. empetrifolia*, it is a good example of the fact that hybrids are often more vigorous than the parents. Single plants may develop into bushes 10 feet high and 15 feet

or more through. It has long been a favourite shrub at Kew for massing in semi-wild places, and numerous large groups are to be seen about the grounds covering what were previously sandy or stony banks, forming undergrowth for thin plantations of trees, grouped in the vicinity of water, and used as hedges. In every instance it gives excellent results. It is increased by cuttings, which should be put into beds of sandy soil in a cold, but close, frame, for they do not root well in heat. After roots have been formed, they should be planted in a nursery border for two years, and then be transferred to permanent positions, as large plants are difficult to establish.—D.

Note from Ashbourne.—Have you got *Salix magnifica*? If not, you ought to do so. My small plant is a cutting in its second year from Kew, and is already in bloom—a peculiarly interesting group of flowers in the shape of an elongated cone—in its present state, purple on top and green below. Then the leaves are soft velvet in texture and glaucous-green in colour. Such a beautiful thing. Do you know that perhaps I am off to the Swedish clergyman and his dwarf Willows? He lives in a wild parish north of the province of Dalcarlia, in Sweden, with miles of driving from the railway station to his house, through Pine forests and mountains. I cannot start until the autumn, as things are not really settled here yet, but it will be a jolly journey in the wildest part of Sweden. Curiously enough, it is within some thirty miles of where I discovered the dwarf Water Lily. I can never thank you sufficiently for teaching me to appreciate the Heaths. I am in the Heath garden every morning watching the development of the various forms. Then there is no glare of colour, but just simple purples and whites, which are restful. I thoroughly agree with your opinion that it is futile to draw up paper plans for gardens. When we were making Mrs. Greer's rock garden we never knew where the next stone or mound was to be placed until it found itself there. With a natural taste, things form themselves naturally, and without that it is impossible to make a garden which is a pleasure to see. Next week I plant out a good collection of Praeger's Mexican and other Sedums which he has collected from everywhere and now intends to classify.—RICH. H. BEAMISH.

Adonis amurensis fl.-pl.—I should not care to put the double variety of *Adonis amurensis* on the same plane as the single one, but, all the same, it is not a plant to be despised, although I prefer single flowers. Seen at its best, *A. amurensis fl.-pl.* is well worth growing. It comes later than the type, and when the flowers first open they are decidedly pleasing. After a few days, however, they lose much of their beauty. In the Edinburgh Botanic Gardens this *Adonis* does very well and is justly appreciated. Of course, opinions differ, but in view of the fact that *A. amurensis fl.-pl.* helps to bridge the gap between the single variety and *A. vernalis*, and that it flowers for a considerable period, I consider it a useful plant.—S. ARNOTT.

— I wish that my friend Mr. Arnott were a trifle more discriminate in commending plants to the notice of readers. His notes, as a rule, are invaluable; but it passes my comprehension how he can say a word in favour of the double-flowering Amoor *Adonis*. I saw the specimen which impressed him favourably in the Edinburgh Botanic Garden, and it tended only to confirm my dislike of its impure yellow flowers with green centres. The single-flowered Amoor *Adonis* is desirable

because it is almost, if not quite, the earliest herb to bloom after Christmas; but, even so, it is inferior in beauty to our old friend *Adonis vernalis*. There is such a bewildering abundance of choice in border flowers nowadays that plants of inferior merit should be rigorously excluded. The double-flowered *Adonis amurensis* is one that I should place in the Index expurgatorius without hesitation.—HERBERT MAXWELL, *Monreith.*

FRUIT.

SEASONABLE NOTES ON GRAPE VINES.

This year Grapes will be somewhat later than usual in ripening, chiefly owing to the fact that less fire-heat has been used in the early stages. The early varieties, such as Black Hamburgh and Foster's Seedling, will not cause any anxiety in this respect, as both the wood and the berries will be thoroughly matured by the end of the first week in September, even if the Vines have been grown under cool conditions throughout. It will be different with the late sorts, such as Black Alicante and Gros Colman. If Gros Colman and other late sorts were started early in March, and only given a little fire-heat during the night, and grown on with the aid of sun-heat from the middle of May till the same time in September, the Grapes will not be ripe before the middle of October. If fire-heat is not used at all then the inexperienced cultivator must make the best of the heat from the sun throughout. This can best be done by closing the houses an hour or so earlier than usual in the afternoon. The closing of the ventilators must always be gradual, and during the stoning period, which takes about twenty-one days, do not close the structure quite so early in the afternoon. From the end of May onwards, after all danger from frost is past, the top ventilators should be opened about 1 inch every night, the ventilation being gradually increased, according to the weather, very early every morning. The temperature of the house must never be allowed to rise very high before opening the ventilators. When the berries begin to colour the house should never be entirely closed, and more front air must be admitted.

THINNING THE GRAPES.—This should not be delayed after the berries have set and commenced to swell. Those with round berries and short foot-stalks should be more severely thinned than others with oval-shaped berries and long foot-stalks. The inner parts of the bunches of late varieties must be more severely thinned than those parts of the bunches of early sorts. The laterals should be stopped at the second or third leaf beyond the bunch. When the berries have just formed the laterals may be tied down to the wires finally without fear of any being broken off. Give a thorough watering so as to saturate the soil to the drainage. Liquid and artificial manures should be given in weak doses after the thinning of the berries is completed, when the berries have stoned, and when they begin to colour. BOURNE VALE.

NOTES AND REPLIES.

Apples—keeping.—Soil and climate have much to do with the keeping of winter Apples. Since I have resided in Surrey on a light, sandy soil, I have found most Apples keep much longer than when grown on heavy soil and a moist climate in the west. About the middle of March I had given me fine, solid fruits of Bismarck grown in Camberley. This Apple I could not keep after the close of the year in the West of England.—J. CROOK.

TREES AND SHRUBS.

RHODODENDRON CILIATUM.

THIS, as may be seen by the illustration, is a remarkably free-flowering species, and is, when not more than 2 feet or 3 feet high, a mass of bloom. The leaves are hairy, and the flowers borne in loose clusters, as may be seen by the illustration, are rosy in the bud state, but after they are fully open become white. From its early-flowering character the blossoms are often injured by spring frosts and cold winds, and it is well to give it the shelter of a cold house so as to save the flowers. It has been largely used by the hybridist in the raising of new varieties.

THE NEWER WILD SPECIES OF LILAC.

THESE should not be planted widely in this country without considerable trials being made, for several have already proved that, although hardy in winter,

latter part of April, and although the buds were well advanced during the period of cold winds, they escaped serious injury.

S. PINNATIFOLIA has not had its leaves injured, but the flowers are crippled.

S. AMURENSIS is very badly injured, and the same thing happens nearly every year.

S. JAPONICA has had both young shoots and flower-buds killed, and *S. pekinensis* and its variety *pendula* are as bad. Now and then the flowers of these two species are produced, and they are then very striking plants, but generally they are not a very great success. Of the better known rare species,

S. VILLOSA is probably the best, and it is closely followed by the commoner *S. Emodi*, which is quite hardy in spring. Of the newer sorts, so far as can be seen at present, *S. affinis*, *S. reflexa*, *S. Julianæ*, and *S. tomentella* are likely to be the most useful. D.

DAVIDIA INVOLUCRATA.

ALTHOUGH originally discovered in 1869, it was not until 1897 that seeds of this re-

ing near the north end of the rock garden is blooming well, and another near King William's Temple is bearing a number of flower-heads. The blooms are in dense globular heads, and are white when expanded, but the conspicuous part of the inflorescence is found in the two large white bracts which surround the flower-head. These bracts are each 4 inches to 6 inches long, and 2 inches to 3 inches wide, a tree at its best presenting a most peculiar appearance, as if the branches were hung with white tissue paper. As the tree at maturity is said to be as large as an ordinary Horse Chestnut, an idea can be gained of its value for decoration. So far as can be seen at present, it is perfectly hardy, grows with the vigour of the common Lime, is not very particular regarding soil, possibly thriving best in good deep loam, and is easily increased by soft cuttings inserted in a close frame in summer or by ripened wood inserted out-of-doors or in a cold-frame in autumn. D.

GARDEN PESTS AND FRIENDS.

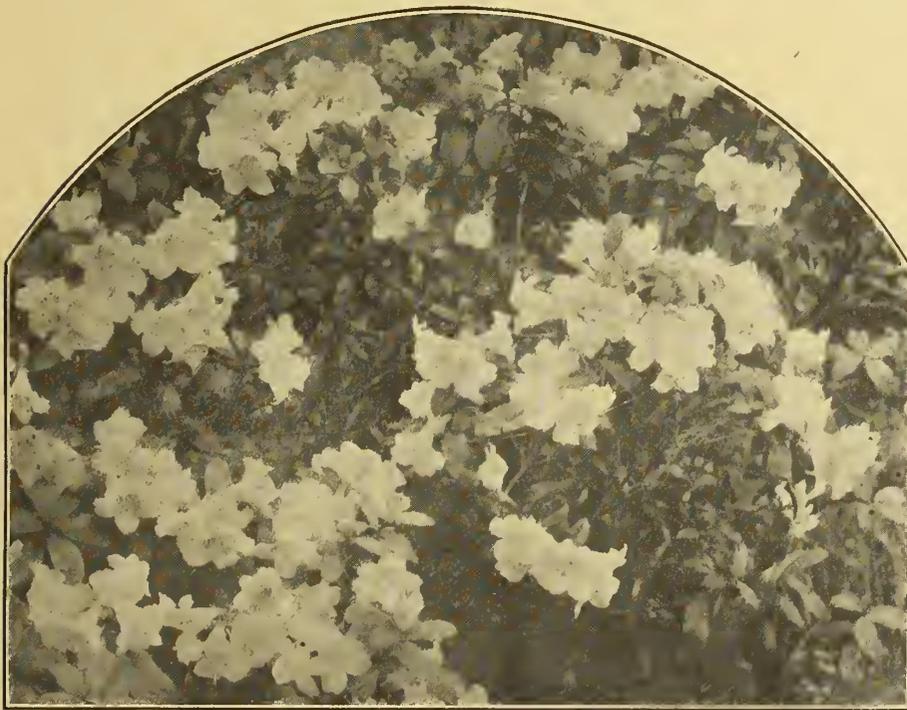

THE TURNIP GALL WEEVIL

(*CEUTHORHYNCHUS PLEUROSTIGMA*, Marsh. = *CEUTHORHYNCHUS SULCICOLLIS*, Gyll.).

THE Turnip gall weevil, or beetle, is at times a source of considerable loss to Turnip and Cabbage crops, though, owing to the fact that injury caused by the weevil somewhat resembles that due to the more serious "finger-and-toe," the presence of the former is not always realised. In the case of finger-and-toe a fungus (*Plasmiodiophora brassicæ*) is responsible for the malformation of the root, while in the case of an attack by the gall weevil the growths are definite galls formed by the larvæ of this insect. Care should be taken to distinguish between the two diseases, as the methods of control are different.

DESCRIPTION OF INSECT.—The adult insect is a small beetle about $\frac{1}{8}$ inch in length with the long proboscis characteristic of the true weevils (*Rhynchophora*). In colour it appears to be black above and greyish on the underside, but if it be examined through a lens it will be seen that the upper surface is sparsely dotted with grey and white scales. Several other species of the genus *Ceuthorhynchus* are harmful to Turnips—e.g., *C. assimilis*, the larva of which lives in the seed pods, *C. quadridens*, which in the larval state feeds in the stems of the flowering plants, and *C. contractus*, which as an adult attacks the seed leaves (cotyledons) of the young plant. The differences between these various species, and, in fact, between the genus *Ceuthorhynchus* and other allied genera of the *Rhynchophora*, are minute, and from the growers' point of view not worth entering into, since each species may be known by the form of injury it produces. The larva is a small shining white or yellowish maggot with a brown head. It is legless, and is found inside the galls usually in a curled up or semi-circular position. The pupa is white. It lies in the earth in a cell formed of particles of soil glued together by a sticky material secreted by the larva.

LIFE HISTORY.—The adult beetles emerge from the pupæ in spring and summer, and the females then lay their eggs in or on the roots of the food plants. On hatching, the young larva feeds on the root, which is stimulated in some way so that it forms a gall. The gall at first is small, but grows gradually until it may attain the size of a small marble, and in many cases several galls coalesce to form a single large out-growth

Rhododendron ciliatum. From a photograph in temperate house in the Royal Gardens, Kew.

they are tender in spring, and both flowers and young shoots are often injured by cold at that season. It is not only the newer ones that are affected in this way, for several of the older wild kinds fail to do themselves justice for the same reason. In the neighbourhood of London during the present spring

SYRINGA ALBO-ROSEA and *S. WILSONI*, referred to by E. H. Wilson in a recent article in *The Garden Magazine* under the name of *S. tomentella*, have escaped injury, and the flowers will now, doubtless, be perfected.

S. REFLEXA is growing well and the shoots are uninjured; no flowers are, however, showing.

S. OBLATA has been badly injured, and it rarely flowers well. Some plants, however, appear to be hardier than others, and a crop of flowers is borne occasionally. It cannot be recommended.

S. JULIANÆ is growing well, and neither young wood nor inflorescences show signs of injury. The same can be said of *S. villosa*.

S. AFFINIS was in flower during the

markable tree were received in Europe by M. Maurice de Vilmorin. The seeds were sown, but one only germinated, and that was planted at Les Barres, where it developed rapidly, and bloomed for the first time in 1906. Cuttings from that tree were rooted, and one was sent to Kew. This was planted in the Himalayan House, where it has grown into a fine tree. In the meantime, Messrs. Veitch sent Mr. E. H. Wilson to China to collect seeds of various plants hitherto known only by herbarium specimens or descriptions, and the *Davidia* was one specially commended to his notice. He succeeded in introducing a large number of seeds about 1900, which germinated well, and a great many seedlings were raised which two or three years later were widely distributed about the country. The tree has grown remarkably well in many places, forming strong and long annual shoots and branching freely. It has flowered in several gardens, and at present several trees are in bloom at Kew. The large plant in the Himalayan House is carrying about 200 inflorescences, whilst one grow-

in which may be found a number of chambers each tenanted by a larva. When full fed the larvæ bite their way out of the galls and enter the earth, where they form the cells described previously and there pupate. The length of time spent in the various stages seems to vary within wide limits. The larval period is said to occupy a minimum of four weeks and a maximum of fourteen weeks, and it is sometimes stated that the majority of the larvae leave the galls in autumn, a few only remaining until March. In opposition to this view were some observations made in the early months of 1914 and 1915, when there were received numerous specimens in which most of the galls were still tenanted by larvæ, none of which pupated before the month of March. The probable explanation is that the beetles emerge irregularly in spring and summer and that the eggs from those appearing early produce a second brood of beetles in late summer, which in their turn may perhaps give rise to a third brood in September. These later broods will also infect a Turnip crop, and larvæ of various ages may be found in the same crop at the same time. The insect, therefore, may spend the winter either as a larva or pupa, and this point is of some importance in considering the various means of control.

PLANTS ATTACKED AND NATURE OF INJURY.—The various forms of Turnip, Mustard, Charlock, Rape, Cabbage, Brussels Sprouts, Savoy, and Kohl-rabi are attacked, but complaints most often refer to the Turnip and Cabbage. In the case of root crops the damage lies in the great loss of crop, which is most marked when the plants are attacked at an early stage. If Cabbage plants are badly attacked they are much stunted and make little "head." The growths produced by the weevil may always be distinguished by the fact that they are hollow and frequently contain a larva. The galls are always more or less rounded, and there is never a production of the elongated finger-like growths formed in an attack by "finger-and-toe." Roots injured by the beetle show little tendency to rot, even after the larvæ have left the galls, while the fungus usually causes extensive decay.

DISTRIBUTION.—The Turnip gall weevil is widely distributed throughout the United Kingdom, and records of its attacks have been received from most English counties. It is also well known on the Continent, and is said to be destructive in France, Russia, and Germany. From the economic standpoint it may be regarded as an insect which is present everywhere, and one which, under certain conditions, may increase sufficiently to cause serious damage. It is likely to become prevalent wherever crops of the Cabbage and Mustard family are widely grown from year to year, or where weeds of this family (such as Charlock) are allowed to spread unchecked. On the other hand, it is controlled, though to what extent is not known, by weather conditions, and by its natural enemies, among which birds must be included. A badly infested field which is not suitably treated must, of course, serve as a centre from which the beetles spread to neighbouring districts.

METHODS OF CONTROL.—(1) Where the Turnip crop is attacked, the Turnips should be consumed as soon as possible, so as to destroy the larvæ before they leave the galls. (2) If a Cabbage crop is attacked the stumps and roots should be burned. (3) After an attack the land should be deeply ploughed to bury or destroy the pupæ. In the case of a garden, trenching may be resorted to or a soil insecticide may be dug in. (4) It is better to

avoid growing Turnips or Cabbages on land adjacent to that which has been attacked the previous year, and in no case should affected land carry in succession two crops liable to attack.—*Leaflet No. 303 Board of Agriculture and Fisheries.*

Wasps.—Already over a dozen queen wasps have at this early date (April 26) been accounted for. Every queen killed now means a nest less to reckon with, and all gardeners—and others—ought to make an effort to lessen the numbers of these destructive and, at times, dangerous insects. In the present case a penny for each queen produced is paid, and this reward results in increased vigilance. A similar premium is given for rats, sparrows, and their nests.—*W. McG., Balmac.*

GARDEN FOOD.

PAPPY FOODS BAD.

ALL food reformers should guard against pappy foods, which are one of the great dangers, owing to the modern facility for milling, by which the noblest of our cereal foods are too often ground to dust and made into unwholesome, soft, wet mushes. These need little or no mastication, so that children and others usually bolt them, to their injury. Such foods should be eaten with the addition of toast or unsweetened biscuit, but they are best avoided altogether. Among the best foods that are spoilt in this way are Oats, Barley, and Rice. Oatmeal is often reduced to a sickly pap, whereas to be good for food it should be cooked dry.

Garden vegetables fare no better from the same pappy treatment; for example, Asparagus and Cauliflower. So cooked, they are only fit for the pig tub, as they leave no residue for the stomach to work upon, and what physiologists call cellulose is an essential in wholesome food.

I lately read in a good-class paper a description of Lettuce cookery, in which good Lettuce is taken from the garden and half-a-dozen things are added to it to spoil it, among them chopped liver and spices. Over-cooking of any food is bad, and all who eat garden food should encourage the free use of salads and other foods, particularly fruits, that do not need cooking as now practised. A very ugly form of pappy food is the use of stuffings in salads. That is defeating the very purpose for which we eat salad, viz., for its wholesome salts and pleasant flavour.

NOTES AND REPLIES.

The best late Apples.—I was pleased to read the remarks of "E. B. S., Hardwick," in your April 15th issue, and to note that he is in agreement as to the four best late winter Apples. In order to increase the number I believe we shall have to go back to the old varieties which have disappeared from most nurserymen's lists. I hear good reports of Ashmead's Kernel, a very old Gloucestershire variety, and I have had some stocks grafted this year. Sykehouse Russet and Rosemary Russet are also recommended, and will be tested. With regard to the Wyken Pippin mentioned by "E. B. S." I quite agree that this is a very nice late Apple, coming in about Christmas. It is crisp, fairly juicy, and clean on the palate, but perhaps a little wanting in flavour, and, consequently, not up to the standard of the other four Apples mentioned. It used to be grown a good deal round here, probably coming over the county borders from Warwickshire, and claims its origin at a village near Coventry called Wyken. As a boy I remember very many old trees in our town and county, but probably they have now died out and have not been replaced, except to a limited extent. One always sees, however, this Apple for sale in the shops of our town about December.

The variety is quite good enough to be included in every good collection of dessert Apples. These Apples make a very nice-looking dish on the table, owing to their perfect shape and pretty appearance.—*F. B., Springfield, Northampton.*

The Peccan (Mrs. Tyndall).—This, known also as the Illinois Nut Hickory, is *Carya olivæformis*, common on the banks of the Ohio and Mississippi, and attaining a height of 60 feet or 70 feet. The Nuts of this species are enclosed in a thin woody husk, and are of a light brown colour, shaped like an Olive and distinctly marked by four slightly-raised longitudinal ridges. They are much superior in flavour to those of the rest of the genus, and can be purchased in our English fruit shops. *MM. Vilmorin et Cie., Paris*, can supply the Melon seeds.

EUGENIE ON SALADS.

LAST summer, when Eugénie first came to live with me, she introduced me to her delightful Belgian salads, and now that the warm days are returning she has her oil-bottle and vinegar-flask out once more, and begs that as I like her salads so much I will write about them for the benefit of other English people. "There are two faults you make," she will often say, "one is that you put too many things in your salad. In Belgium we never have a salad with Lettuce and Watercress and Beetroot and Tomatoes and slices of egg all together; we much prefer to put only one or two different kinds of greenstuff and no egg. And in the second place, there is a great art in the proportions of the dressing. Never have I tasted a salad in England in which the dressing had not too little pepper and oil, and far too much vinegar. You English are afraid of oil."

Eugénie says that in Belgium, as here, the staple vegetable for salad is the Lettuce. Often a Belgian salad is composed of nothing but a Lettuce, properly prepared and dressed, and very refreshing it is, but another way is to mix Lettuce and Endive in equal quantities, or sometimes Endive and just a little Watercress. The quantities must not be equal in the last case, Eugénie taught me, as Watercress is so much stronger in flavour, and would predominate unpleasantly if much were used.

Eugénie blames the way we English housewives wash our greenstuff for salad, often letting it lie in water for a long time till it loses its crispness. Her own method is to wipe the leaves over (after removing two or three of the dirtiest and outermost) with a clean, damp cloth. This takes time, it's true, and when she is in a hurry she plunges it instead into a bowl of very cold water for five minutes.

"So often English salad is too wet. You do not dry it properly," she told me. "In Belgium we have a special wire basket in which to swing it till every drop of water has drained away. But here you can manage quite well if you first drain in a colander, and then shake in a clean cloth till all the moisture has gone. Salad can never be nice if it is sodden with water."

BELGIAN SALAD DRESSING.—Ingredients: 1 tablespoonful of salad oil, 1 saltspoonful of salt, pepper to taste, 1½ dessertspoonfuls (3 table-spoonful) of vinegar, 1 saltspoonful of mustard (if liked).

These are the correct proportions; the actual quantities used must depend on the size of the salad. It is easy to mix too much, more than the salad will absorb; there should never be a little pool of dressing left at the bottom of the bowl.

Mix the ingredients well together in a cup, and only add to the salad a minute or two before serving—in Belgium, in fact, the dressing is made and mixed in actually at table. Put in about half a table-spoonful at a time, mixing that quantity well before adding more, and your salad is certain to be delicious.—*Home Cookery.*

PLANTS AND FLOWERS.

ROOM AND WINDOW.

TWO HARDY SHRUBS IN MARCH.

IN spite of the disusual rainfall and cold spring the Portuguese Heath was as beautiful as ever, and, gathering it, I put a few sprays of our native *Andromeda* (*A. polifolia*) in a vase with it. Both did very well together and looked very well indoors. Both are of easy culture in our own land. There is a large as well as a small variety of the native *Andromeda*,

and rest. To keep plants pent up for weeks and months without any air is not the way to keep them healthy. All plants require air more or less, and although the freshness of the air may be said to be very seldom felt in our large towns, yet, by keeping the leaves of the plant clean, they are the better able to breathe what there is. A

SOIL most suitable and most comestable for all window plants to grow in can be found in any locality where there is a hedge. Pull up the first big tuft of Grass from the side of the hedge by the roadside, shake the soil from it, add a handful of sand, and the mixture will suit almost

leggy; try, by timely stopping of the shoots, to keep them as bushy as possible, and near the pot. We now come to the rest of plants. Nearly all plants grown in pots require rest in due season, and that season is usually after they have done flowering. All plants that have flowered during summer, such as *Pelargonium* and *Fuchsias*, are easily rested by being kept moderately dry at the roots all through the winter. In fact, the *Fuchsia* should be taken out of the window altogether during that season, and placed away in some dryish cellar, or on a shelf, free from frost, to remain there until spring again comes round. It should then be brought

The Portuguese Heath (Erica lusitanica) and our native Andromeda (A. polifolia).

and both are worthy of much more attention than is given them. W.

WINDOW PLANTS.

WITH plants cleanliness is essential to healthiness. Therefore, whatever plants may be growing in the window, the dust of the dwelling must not be allowed to accumulate on the leaves week after week. They should be carefully washed every now and then with a sponge and tepid water. This should be done carefully leaf by leaf, so as not to injure the plant. This operation not only keeps the leaves free from dust, but also from insects. Window plants require air, food, light, training,

any window plant. In potting plants be sure to give them good drainage. To effect this, before putting the soil into the pot fill up about one-sixth part with rough pebbles or broken brick. This will enable the water to run freely from the soil and prevent its becoming sour. Press the soil evenly and firmly round the plants, and you have now the chief features required in potting all plants. In summer-time the plants will require almost daily waterings, and an occasional sprinkling over the foliage will be beneficial. This brings us to the

TRAINING. Plants of the *Pelargonium* tribe should never be allowed to become

forth, re-potted in fresh soil, set in the window, and away it goes on the journey of life.

Thus, it will be seen, to keep window plants healthy the leaves must be kept clean, they must have plenty of air, must be potted in good, sandy soil, well drained, and have a sufficiency of water when growing. Train them carefully, and after the exertion of flowering give them a rest.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

OUTDOOR PLANTS.

NATURALISING SPRING FLOWERS.

It is only necessary to see a good example of natural grouping to realise its importance as compared with the more common practice of planting in beds. Groups of Daffodils of uneven outline with a few bulbs breaking away from the main group, here and there, are far more picturesque than any set arrangement. In a meadow some five or six acres in extent, and which is mown each year for hay, the following, flower freely. Falling rather sharply to the south it is thus an ideal place for such a form of gardening. Along the lower side is a small lake, on the banks of which are long drifts of Daffodils, which revel in the cool, moist soil at the water's edge. With the advent of the New Year a few flowers of *Crocus Imperati* appear on the higher ground, and these are followed by other species, such as *C. Sieberi*, *C. biflorus*, *C. vernus*, *C. susianus*, followed also in their turn by other species and numerous varieties. With the end of January and early February a few flowers of the beautiful pale sulphur Bayonne Daffodil (*Narcissus pallidus præcox*) and the little *N. minimus* appear, and close on their heels come the Tenby Daffodil and the Dutch and Cornish minor. February and March bring a further variety of flowers, including Snowdrops.

THE SPRING SNOWFLAKE (*Leucojum vernum*), and the larger form, *L. vernum carpathicum*, both succeed in the Grass. Some of the Snowflakes are in bloom in January, but they do not display their greatest beauty until the following months, when their drooping and sweetly-perfumed flowers, tipped with green, are very attractive. The Summer Snowflake (*L. æstivum*) is a taller plant, which bears several flowers on 2 feet stalks. It is an excellent plant for moist or even boggy places, and should be planted by the waterside, where such exists, or near a small stream if there happens to be one passing through the garden, or in low woodland soil. A little group of this Snowflake—with me—has been under water all the winter, having been planted by a small stream where it enters the lake, and this is stronger and healthier than others less favourably situated. There are other varieties, of which one called Gravetye Giant is the finest I have seen. This handsome form grows 3 feet high in strong loam and carries many flowers.

DOG'S-TOOTH VIOLETS (*Erythronium*) thrive in the Grass, their mottled leaves—always a source of attraction—and delicate-coloured flowers endear them to all lovers of hardy plants. There are several kinds, ranging in colour from white to pale pink, rosy-purple, and yellow. To enjoy them, sunny, sheltered positions should be chosen, as hailstorms are liable to destroy the delicate blooms. A small colony of these is beautiful when pushing the half-expanded blossoms through the Grass. They are also lovely planted at the base of deciduous shrubs, where the flower-stalks are usually longer.

THE WINTER ACONITE (*Eranthis hyemalis*) comes about Snowdrop time and flourishes in the Grass, although it seems happiest in thin woodland, where it spreads rapidly, especially on warm, light soils. Snowdrops planted near by give additional beauty to these yellow carpets.

WINDFLOWERS.—The Scarlet Windflower (*Anemone fulgens*), perhaps the most striking flower for naturalising in Grass, is annually a feast of colour and does not die out as it often does when planted in rich, made-up soils. Plant where it may

get the full amount of sunshine during the early part of the day. Usually at its best during April. The Star Windflower (*A. stellata*) is not happy in our heavy soil, but, given a warm, sheltered position on sandy soil, it would probably be a success. *A. nemorosa*, both single and double forms, unless abundant in the district, should be included, as it comes into bloom towards the end of March and roams about in an interesting manner. There are some forms of this much better than others. The Yellow Wood Anemone (*A. ranunculoides*), another little native, strikes quite a different note of colour among the Windflowers. Its deep yellow flowers, each about $\frac{3}{4}$ inch across, are a feature towards the middle of April. This requires a warm, sheltered spot to bring out its full beauty. A distinct feature of this kind is that it occasionally bears two flowers on a stem. The Blue Wood Anemone (*A. Robinsoniana*) is undoubtedly one of the most lovely spring flowers in cultivation, and, beautiful as some of the other Windflowers are, would be my selection from this large family were I limited to one kind. Scarcely taller than the other Wood Anemones, and in colour a delightful soft lavender, when fully expanded under the influence of the morning sunshine it becomes one of the most fascinating subjects of this large collection of spring flowers. With me it is growing and flowering in profusion on both the sunny and shaded sides of this meadow; indeed, whether it be in cold, bleak spots by the waterside or under the shade of trees, the flowers are equally plentiful, and a few plants quickly spread into small colonies. The soft colour of the flowers is lit up by a central bunch of bright yellow stamens. As an edging to beds on the rock garden or in shady hedges it is very satisfactory. The Greek Windflower (*A. blanda*) commences to bloom early in February and continues in great beauty until the end of April. There are pale blue, deep blue, pink, and white forms of this, and the charming new variety (*A. blanda scythica*), whose petals are white inside and pale blue on the outside. *A. blanda* is the first of the Windflowers to bloom, and for this reason is a most valuable plant, growing rarely more than 6 inches high and bearing flowers each 2 inches across. This should be planted in sheltered nooks, where the storms—so prevalent during its flowering period—are somewhat broken. The Greek Anemone does not spread with the same rapidity as does the Apennine Anemone (*A. apennina*), which, although easily mistaken for *A. blanda*, is a different plant, and comes into bloom quite a month later. *A. apennina* has a creeping rhizome, whereas *A. blanda* has a round bulb-like root. About the middle of April the majority of the

DAFFODILS which create such a wealth of colour come into bloom. Here the large and handsome forms are grouped in great numbers, generally one variety in a place, and in certain instances other dwarf flowers are springing up amongst them. Such miniature species as the Cyclamen Daffodil (*N. cyclamineus*), *N. triandrus*, of which Angels' Tears (*N. triandrus albus*) is a great favourite, Hoop Petticoat Daffodil (*N. Bulbocodium*), Musk Daffodil (*N. moschatus*), *N. Johnstoni* Queen of Spain, a flower as beautiful and graceful as the choicest Lily, are so fragile that they should be grouped near the paths. Planting should not be done in any haphazard manner, such as is often seen in illustrations where the whole surface of the turf is covered with plants, but the most promising positions for the various

subjects should be selected, taking care to leave stretches of bare ground, which give relief and go far to enhance the beauty of the flowers themselves. If this is done no further care or attention is required for years.

GRAPE HYACINTHS (*Muscari*) are excellent for naturalising in the Grass, and where they are allowed to intermingle with Narcissi or the scarlet Windflower a beautiful effect is obtained. Sufficient numbers should be planted to emphasise their real meaning, and a plantation should be made in both sun and shade. Here they are grouped on the higher ground, but this is not absolutely essential to their success. There are several kinds, but the following have proved very satisfactory here: *Muscari conicum* Heavenly Blue, perhaps the gem of this group, of delicious fragrance and in colour a lovely rich Gentian blue. The little bells are freely produced on stout stalks a foot in height, half of which is clothed with flowers which last a long time. *M. racemosum*, a native plant, has very dark flowers, almost black, with little white teeth at the mouth of the bells. *M. botryoides* is an old garden favourite and eminently suitable for this class of planting. All these spread freely. A single bulb will form a number of side bulbs in a few years, and these will send up between fifteen and twenty flowers, which are at their best during April. They are very beautiful as edgings to beds or planted among Azaleas and other summer-leaving shrubs.

SNAKES' HEADS (*Fritillaria Meleagris*).—The flowers of these range in colour from pure white to claret-purple, many of them beautifully mottled; indeed, the variety of colour is one of their great charms. The flowers are freely borne on long, graceful, arching stems. A plantation was made here many years ago in a moist position on the rising ground above the water, and these have annually seeded and increased to such an extent that they now cover a considerable space. We also have them planted on the higher ground of this meadow, but they are not so happy as when growing in moist places. Under trees and in long, wide lines by the sides of little streams they are splendid.

CROWN IMPERIAL (*Fritillaria imperialis*) is a stately plant admirably adapted for grouping in open woodland near the rides or in the warm soils of hedgerows, where its stout stems reach from 2 feet to 3 feet in height and bear several bell-shaped flowers beneath a crown of fresh green leaves. There are various colours, all of which are handsome, but emit a rather unpleasant odour. April and May are the months for their flowers.

LILY OF THE VALLEY is quite happy in loose soil, such as is often met with in old woodlands where decayed leafy material has accumulated.

STAR OF BETHLEHEM (*Ornithogalum*) succeeds in the Grass and in open woodland soils.

SQUILLS.—The Italian Squill (*Scilla italica*) is one of the most valuable Squills for grouping. It has spread so freely here that it annually forms a sea of lovely pale blue not more than 6 inches high. There are light and darker varieties. The Spanish Squill (*Scilla hispanica*) is a fine, robust plant which grows from a foot to 18 inches high and produces numerous large, bell-shaped, deep blue flowers. This is the largest of the Squills and is a grand plant for slightly shaded spots. It will also succeed in the sun. Flowers in May and June. Should a small grove or cool wood be near the garden the native Blue-bell in the various colours should be freely planted. Should a small stream wind its

way through the garden Solomon's Seal should grace its banks, and the Pontic Kingcup as well as our native *Caltha palustris* be planted at the water's edge.

This list could be greatly extended, but I hope sufficient has been mentioned here to show the endless variety of hardy spring and early summer flowers. In this

THE BLOOD-ROOT.

(*Sanguinaria Canadensis*.)

The Canadian Blood-root, so called on account of the coral-red colour of its root, is a charming spring-flowering plant too seldom met with in gardens. As the accompanying illustration shows, it grows

Part of a group of the Blood-root (*Sanguinaria canadensis*) at Lilford Hall, Oundle, Northants.

form of planting the great danger is that of overcrowding and the indiscriminate mixing of colours instead of grouping freely those of distinct shades separately. Some of the blues are beautiful if planted alone or near yellow or scarlet flowers, but if another shade of blue is brought near, the effect of both is lost.

Sussex. E. MARKHAM.

BLUE WINDFLOWERS IN THE GRASS.

THESE have been very beautiful this year, and best of all, perhaps, the azure form of our native Wood Anemone. *A. apennina* is very good, too, but it is apt to go too quickly in the sun, and its right place is a shady lane, if one has it. The Greek Anemone, *A. blanda*, is also very beautiful, and some of its flowers are unusually large, but we have yet to prove that it will survive on our close turf where the Apennine and the English blue Windflowers do so well.

I have striven for many years to praise our English blue one, but, looking at it this year in the full sun, I think I have not said quite enough. It beats them all for beauty and perfect hardiness and freedom of growth. It came originally from Ireland, where our Anemone, in certain gritty soils, varies very much. In turf in April it is one of the most lovely things one can have for the wild garden, and that without any labour or care beyond the first planting. The ground in which these blue Anemones grow with me is mown in May, by which time all the flowers and leaves are gone, and the ground is even mown a second time in the autumn without the least hurt to anything. I have had it in all sorts of positions—on low walls, running about among the wild Primroses, in the Grass, on banks, and it is happy in all. W. R.

The Caucasian Leopard's Bane.—The oft-given advice to break up certain perennial plants at intervals receives strong support from the behaviour of a big plant of the Caucasian Leopard's Bane, which the force of circumstances has prevented me from breaking up at the same time as others. It has spread into a mass about 2 feet across, and has gradually become less and less free flowering. Other much smaller plants, which had been properly attended to, are really fine in their way with their golden blooms, but this one has hardly any flowers, and these are small and on short stems. *Doronicum caucasicum*, even at its best, may not be a first-class plant, but we must not be too fault-finding with early-flowering plants.—S. A.

with us on a bit of low rockwork facing east, in a position partially screened from the direct rays of the sun during the greater part of the day, and when the flowers open the plant produces a dazzling effect. The glaucous, whitish leaves, too, are ornamental in the border or rock garden. It thrives in a sandy loam. The best time for planting is from October until February, and there are many favourable sites to be found which would

Veronica repens in the rock garden. From a photograph sent by Mr. C. Turner, 3, Kenwood-road, Highgate, N.

gain in beauty by the introduction of this pretty, inexpensive plant.

F. W. GALLOP.

Lilford Hall, Oundle.

NOTES AND REPLIES.

Trumpet Daffodil Van Waveren's Giant.—Possibly a little coarse, this is yet a noble and valuable variety. It is not possible to judge of its value by a bloom or two, but in good clumps in the garden or when a few are arranged in a vase their value may be best

understood. I saw some clumps in the gardens of Sir Robert W. Buchanan-Jardine, Bart., at Castle Milk, Dumfriesshire, the other day, and very handsome were the flowers. The deep-yellow trumpet is flanked by a broad, lighter-coloured perianth, which is of great substance. It is, of course, not a novelty now.—S. A.

Arabis alpina grandiflora.—The desire to possess something better than usual leads one to purchase some novelty under the name of *grandiflora*, or *major*, or *superba*, or even *magnifica*, and the result is often disappointment. *Arabis alpina grandiflora*, which was sent out with a flourish of trumpets, is a coarse grower, and not nearly so desirable as the closer-growing *Arabis alhida compacta*. *A. alpina grandiflora* does not flower freely, and the slightly larger blooms do not compensate for the loss of other qualities.—S. A.

Tulipa sylvestris.—This is a pretty species for naturalising in short Grass. A small group has been in existence here for ten or more years, but the bulbs are now getting very weak and flowers are but few. No doubt, the heavy soil of this garden has had much to do with the failure, added to which the bulbs were planted where they get too much shade from the overhanging boughs of an Oak-tree. In light soil the shade would not matter. A desirable quality of this yellow Tulip is its fragrance.—G. T.

Trumpet Daffodils at Castlemilk, Dumfriesshire.—Narcissi are very largely grown in the gardens of Sir E. W. Buchanan Jardine, Bart., Castle Milk, Lockerbie, both in the Grass and in the garden. King Alfred is a favourite, the flowers on their sturdy, erect stems being very useful for cutting.—A. S. D.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

VERONICA REPENS.

The illustration we give to-day shows how valuable this Speedwell is as a carpeting plant. I have seen enough of it to think it preferable to the two most acceptable for that purpose—the dwarf *Mentha* and the green *Sedum Lydium*. It is a dense, close-growing creeper, covering the soil as it extends with a soft carpet of bright-green leafage, only needing occasional lateral trimming to keep it within bounds. It seems to thrive well on

soil that is moderately dry. Those in want of a good carpeting plant should try this mountain Veronica. T.

Corydalis Alleni.—For an alpine-house this *Fumitory* may be recommended, as well as for the rock garden. A pan of this *Corydalis* in one of the houses of the Royal Botanic Gardens, Edinburgh, was attractive in the beginning of February. It was raised by the late Mr. James Allen, of Shepton Mallet, and is charming with its heads of creamy-white flowers prettily marked with purple.—S. ARNOTT.

INDOOR PLANTS.

SWEET-SCENTED RHODODENDRONS.

One of the most fragrant of all Rhododendrons is the Himalayan *R. Edgeworthi*, which is readily distinguished by its somewhat straggling habit and woolly branches. The leaves have strongly-marked veins, and are clothed on the undersides with a rusty-coloured tomentum. The flowers, borne in loose heads, are pure white, except a yellow stain on the upper part of the interior. Unless in particularly favoured parts of the country, such as in Devon and Cornwall, this Rhododendron is tender, hence it is commonly regarded as a greenhouse kind. The fragrance is so pronounced that a very few expanded blossoms will make their presence manifest in even a good-sized structure. This delightful feature has led to its being employed by the hybridist in the production of new varieties, in all of which the fragrance of the original species has been perpetuated. One of the first was Princess Royal, a hybrid between *R. Edgeworthi* and *R. ciliatum*, while others that owe their origin to *R. Edgeworthi* are *R. fragrantissimum*, *R. Sesterianum*, *R. Lady Alice Fitzwilliam*, and *R. Fosterianum*, the last a cross between *R. Edgeworthi* and the Moulmein *R. Veitchianum*. It is scarcely so fragrant as some of the others, but the blossoms, white with a yellow blotch, are magnificent. The late Mr. Isaac Davis, of Ormskirk, raised a dwarf-flowering race from *R. Edgeworthi* and *R. multiflorum*, this last itself a hybrid. These Ormskirk hybrids include Countess of Derby, Countess of Sefton, Duchess of Sutherland, and Mrs. James Shawe, all fragrant. All of the above-named Rhododendrons can be propagated by cuttings of the half-ripened shoots, dibbled into pots of sandy peat, and placed in a close propagating-case in a warm structure. They stand some time before rooting, but, as a rule, the loss is small. When grown into good-sized plants these Rhododendrons form during their flowering period a delightful feature in the greenhouse or conservatory. They may, with advantage, be stood out of doors during the summer months. In the case of large specimens established in pots or tubs they will stand for years without re-potting, though they are greatly benefited during the growing season by an occasional dose of weak liquid manure and soot-water combined. W. T.

NOTES AND REPLIES.

Forcing the Laburnum.—Would the Editor kindly say how to bring on flowering trees in the greenhouse, as there are some young Laburnums which look as if they would bloom if brought into the house for next spring?—J. H.

[Unless the Laburnums have been moved annually, or are established in pots, we cannot hold out any hope of your being successful in flowering them in the greenhouse. Some shrubs with close masses of fine roots, such as Azaleas, Deutzias, etc., may be lifted in the autumn directly the leaves drop, and, if potted at once and watered when necessary, can early in the New Year be taken into a structure where a temperature of 45 degs. to 55 degs. is maintained, shifting them, as they develop, into a house 10 degs. warmer. With this treatment they will flower in a perfectly satisfactory manner. In the case of the Laburnum, however, the root-fibres are very few, the main system being a few stout roots of a deep descending nature. It is, therefore, obvious that if the plants have not been lifted recently their long roots will suffer so much in digging them up that flowers the following spring cannot be hoped for. The only

course open to you in dealing with your own plants is to lift them carefully in the autumn and pot them in some good soil, after which they should be plunged out of doors and kept watered. The summer after this they should make good growth if attended to with water and given an occasional stimulant. It is very necessary that they are plunged in a spot fully exposed to sun and air. They should then form flower-buds which will develop under glass if treated as above advised. In the autumn you can always purchase Laburnums which have been especially prepared for forcing.]

Salvia patens as a pot plant.—Having tried various ways I found the best results were obtained by growing three plants in an 8-inch pot. This is easily done either by striking three cuttings in a 4-inch pot or putting three seedlings into the same sized pot. When well rooted they are shifted into the 8-inch pots, using good rich soil and placing them in an open position out-of-doors. When the pots are full of roots they should be given manure-water twice a week. It is a good method to pinch them to make them break. Another advantage of these pot-grown plants is that the following spring they give fine, strong cuttings, and can then be planted out in the open air. By putting three of these pots 2 feet apart they make a big group and give a mass of colour for months. I have found the plants winter best in pots in a cold frame, protecting in very severe weather.—WEST SURREY.

VEGETABLES.

TRAPPING MOLES.

ALTHOUGH it has been proved that moles devour huge numbers of wire-worms, leather-jackets, and other noxious grubs, most agriculturists—especially gardeners—prefer their absence to their company, and for very good reasons. There are various ways in which they can be disposed of, poison being one. This generally contains strychnine, and some worms, being sprinkled with the powder, are distributed in the runs. Many people, however, have a dislike for using poison of any kind, and it is certainly liable to be picked up by fowls or other live stock. The alternative is to trap the moles, and as it is neither necessary nor essential to employ a professional mole-catcher (save where the area is great), a hint or two here may enable the inexperienced to succeed in the job himself.

There are two main types of traps in general use—the wooden barrel and the steel (or pincher) trap. The latter I generally use, for it is much easier to set. It can be purchased for about sixpence at most ironmongers, is very simple, and, if properly used, is an infallible device. The great thing to do is first to find the right kind of run in which to set the trap. For instance, never attempt to catch moles in those surface workings which make unsightly and injurious upheavals in straggling lines about our seed-beds or turf. These are merely feeding tracks, and the enemy will seldom pass that way more than once. We must go deeper, to those permanent highways which may be anything from 4 inches to 8 inches below the surface. To locate one of these is the hardest task, but a little observation will soon help one over the difficulty. There is always, for example, at least one such run between two mole-hills, and a trained ear can detect its position by the hollow sound of the ground above it. Then these runs often emerge into the open on the edge of a pathway, or from the walls of a surface

drain or hedge-bank. When discovered, one has only to cut through the passage a square hole sufficiently large to take the trap, with its extended prongs resting on the bottom of and upon either side of the line of traffic. When set, cover the trap with pieces of turf and put some soil on the top of that so as to exclude light, taking care not to prevent the free action of the springs (or handles), which expand when sprung. It is often said that moles are shy at the odour of one's hands, but I never take any precautions in that respect. There is, however, one particular point to observe. When the hole for the trap is cut, and before the latter is set, see that there is no loose soil left in the runs on either side. If there should be, the mole will push this ahead of it as it comes along, and the trap will be set off before the animal enters it.—A. T. J., in *Farm and Home*.

NOTES AND REPLIES.

Treatment of soil.—Would you please give me a little information as to what I can do with a piece of ground over which a shed has been built for some years. The soil is sandy, and though the shed has been removed since last December the wet has only gone down about 3 inches, consequently when dug it comes up like so much dusty sand; in fact more like silver sand. I have a heap of manure consisting of horse-droppings taken from the roads, rotten leaves, wood ashes, and garden refuse, over which have been thrown all kinds of household slops. Would this be good enough to dig in, and would the plot of land do for green stuff, such as Brussels Sprouts, Cabbage, Savoys, etc.? If so, please say whether I should put it in now or just before planting, and if it should be put in deep. The size of plot is about 30 square yards open to south.—L. J. M., *Woking*.

[Get the piece of ground deeply dug, incorporating with the soil all the refuse matter you speak of. After it has settled down you may plant on it any of the Cabbage family as you suggest.]

Sowing some vegetables.—More might be done with Beet. In order to extend the season at the beginning I always sow a crimson Turnip-rooted variety in boxes under glass, and after hardening the plants off plant them out as soon as ready. I have transplanted Beet, both Turnip-rooted and tap-rooted varieties, and always successfully. Good white and red Celeries should have been raised in a warm frame on a mild hot-bed, and pricked off when ready, the first batch in a frame, blanching with paper for flavouring, and others for planting in trenches when ready. Do not permit a check from drought or other causes, as that will result in pithy stems and inferior produce generally. Celery plants for very late use should be sown outside very thinly and transplanted into shallow trenches when ready—not later than August, early in the month—after an early crop of Potatoes or Peas.—E. H.

Hardiness and colour.—There may possibly be some connection between hardiness and colour in the case of vegetables. For example, red varieties of Celery resist extreme cold better than those which are white, and I have just been comparing two well-known kinds of garden Turnips—Golden Ball and White Stone. A sowing of each variety was risked on a warm border rather early in April. Both germinated well, and the lines were almost ready for thinning when rather a sharp snap of frost occurred. Of White Stone not a plant survived, while the line of Golden Ball, side by side, was unaffected. Of course, there is the danger that the check may yet result in wholesale holting; but the point is that, apparently, Golden Ball is hardier, and that, like the Red Celery, it is of a stronger constitution than the white varieties.—KIRK.

Savoy Dwarf Early Ulm.—A sowing made in the early days of May will give plants ready for putting out after the first Potatoes are lifted. Many who do not care for the strongly-flavoured larger Savoys might appreciate this fine little variety. It hearts in during the early winter after Cabbages are almost exhausted, and fills up a blank between these and Brussels Sprouts. Being a small variety, Early Ulm can be planted almost as thickly as Lettuces.—KIRK.

ROYAL HORTICULTURAL SOCIETY.

MAY 16TH, 1916.

The dominant note of the fortnightly meeting held on the above-named date was the display of late-flowering Tulips. In excellent condition, for the most part, some bore evidences of the recent heavy and continuous rains, which, when excessive, mar the beauty of these bold May-flowering sorts. Roses were very finely shown. Carnations and alpine plants were much below the average, though an assortment of the newer mossy Saxifrages marked the progress of this useful class.

TULIPS.

Messrs. Dobbie and Co., Edinburgh, had one of the finest displays, the flowers large, clean, and well and imposingly staged. Finer Tulips have rarely been seen. Some of the sorts of outstanding merit were Golden Crown, of Bouton d'Or colour, the flowers twice as large, Farncombe Sanders, a brilliant variety, La Tulipe Noire, one of the darkest, Clara Butt, indispensable, Orange King, Gesneriana lutea, Golden Beauty (syn. Bouton d'Or), Mme. Krelage, and Louis XIV., of old bronze tone.

Messrs. Barr and Sons, Covent Garden, W.C., arranged a magnificent bank of Tulips practically covering the whole of the western end of the hall. Here the stately Darwins vied with the Cottage kinds, each excelling in its own particular way. Salmon King, Clara Butt, Loveliness, Nauticus, Zulu, Psyche, Suzon, The Fawn, Europe, Margaret, and many others represented the former, while Inglescombe Pink, I. Yellow, Gesneriana lutea, Golden Bronze (a lovely thing), and Orange King were some of the better Cottage sorts.

Messrs. R. W. Wallace and Co., Colchester, arranged a collection on a low double table, and here, too, a great feast of the flower was set out in bold groups. Ellen Willmott (long, elegant form, pale canary colour), Louis XIV. (rich purple and bronze), Beauty of Bath (soft yellow), Avis Kennicott (a fine new yellow Cottage), Baron de Tonnay (still one of the best), Clara Butt, Chameleon, and La Merveille, whose pointed, orange-red, salmon-flushed flowers render it distinct, were some of the best.

Messrs. R. H. Bath, Limited, Wisbech, had a lovely lot of flowers, Queen of Roses, Maiden's Blush, Bronze Queen, Golden Crown, Clara Butt, and the very dark Philippe de Commines being a few of many well shown.

Messrs. Waterer, Sons, and Crisp, Bagshot and Twyford, staged a superb collection of the flowers interspersed with Acers and other things of a light character. In this collection Parisian Yellow was a notable sort. Other good sorts were Sunset (scarlet and gold), Inglescombe Scarlet, Fairy Queen (bronze and gold), Gesneriana spatulata (a giant of resplendent colouring), Zulu, The Sultan, and La Candeur. Cut trusses of Rhododendrons Alice, George Hardy, and Pink Pearl occupied prominent places at the margin.

Messrs. Robert Sydenham, Limited, Birmingham, also displayed a representative gathering of the best, while Walter T. Ware, Limited, Bath, showing a small collection, contributed the four novelties of the occasion.

ALPINE AND HARDY PLANTS.

Mr. G. Reuthe, Keston, Kent, staged a considerable collection of choice alpinists and hardy Orchids. Of these we remarked a particularly well-flowered lot of *Oxalis enneaphylla*, *Myosotis rupicola* (rich blue), *Pentstemon Davidsoni* (miniature, shrubby kind, with scarlet flowers), *Haberlea*, *Veronica cinerea* (greyish of leaf and blue flowers), and the too rarely

seen *Anemone narcissiflora* (red in bud, pure white when expanded). *Primula muscariflora* and *P. Forresti* were remarked, though even more beautiful and distinct was an unnamed *Primula*, in some respects a glorified *P. capitata* with imperial purple flowers horizontally disposed.

Mrs. Lloyd Edwards, Llangollen, had many hybrid mossy Saxifrages, two of which, J. C. Lloyd Edwards and R. F. Wickham, received Awards of Merit. Apart from these we noted Red Dwarf (very bright), *sanguinea* (one of the best reds), and White Lady (early and most prolific). A *granulata* hybrid, Mrs. Garnett Batfield, only suggests that the hybridist has gone too far, and that *S. granulata* and the Mossies are not happy marriages.

Mr. G. W. Miller, Wisbech, contributed freely of border Auriculas, Polyanthus, Violas, some two dozen varieties of *Trollius* in ample bunches, and other hardy flowers.

Messrs. Barr and Sons contributed freely of *germanica* and intermediate Irises. Messrs. Reamsbottom, Geashill, Ireland, showed Crown Anemones well and in great variety.

AURICULAS.

Mr. James Douglas, Great Bookham, had a delightful lot of these flowers, the alpinists being in particularly strong force and good variety, while fancy and show sorts were also prominent.

ROSES.

Of these, Mr. Elisha J. Hicks, Twyford, had both showy and interesting examples; also more than one novelty. Of the latter, the more conspicuous was *Rosa Moyesi Brilliant*, a seedling from the type, having larger flowers of rich reddish-carmine. *R. sericea pteracantha* (white) was also shown in flower. Charles E. Shea, new H.T., which received an Award of Merit, is of long and shapely outline, rosy-peach with salmon in colour, and delightfully fragrant.

Messrs. Frank Cant and Co., Braiswick Rose Gardens, Colchester, showed some excellent Roses, Mrs. Foley Hobbs, Lady A. Stakely (pink), Juliet, the velvety-crimson George Dickson, and Mrs. C. E. Salmon (single pink) being some of the good ones.

Messrs. B. R. Cant and Sons, Old Rose Gardens, Colchester, had a goodly showing of Fortune's Yellow, Silver Moon (single white), Cupid (single pink), Mrs. Herbert Stevens (lovely pure white of splendid form), Sallie (blush), Autumn Tints (apricot), Snow Queen, and others.

SHRUBS.

Messrs. Gill and Sons, Falmouth, brought a brilliant lot of *Embothrium coccineum*, *Andromeda japonica*, the miniature blue *Rhododendron fastigiatum*, *R. Kewense* (very fine form), and many other hybrid *Rhododendrons* were also staged.

Messrs. Piper and Co., Bayswater, had a table of Clematises, *Daphne Cneorum*, *Cytisus* of sorts, and other plants. Messrs. Cutbush had a fine display of *Azalea altaclarensis*, with *Hydrangeas* in blue, pink, and white, together with a big batch of *Primula pulverulenta* and *P. p.* Mrs. Berkeley.

GREENHOUSE PLANTS.

Messrs. Whitelegg and Page, Chislehurst, brought a particularly good lot of *Schizanthus Chislehurst* Giant strain, rich in violet and purple shades, the white and pink varieties being not less attractive. Messrs. H. B. May and Sons, Edmonton, had a table of Palms, Ferns,

and Verbenas in variety. Messrs. R. and G. Cuthbert filled a double table with tall-growing *Antirrhinums* in named sorts. The plants had not reached the zenith of their flowering.

ORCHIDS.

Only one group was staged, this coming from Mr. F. Menteth Ogilvie, The Shrubbery, Oxford. The group was particularly rich in *Odontoglossums* and *Odontiodas*, O. Mrs. F. M. Ogilvie, a very dark variety, being one of the best. *Cattleya Empress Frederick alba* (white with yellow throat) was also remarked. This exhibitor also showed the only novelty—*Miltonia Ilyeana* F. M. Ogilvie Shrubbery variety—for which an Award of Merit was granted.

A complete list of the certificated plants and medals awarded will be found in our advertisement columns.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM MAY 11TH.—*Rock Spray* (*Cotoneaster horizontalis*), *Genista hirsuta*, White and yellow Broom, Bush and climbing Honey-suckles, Hardy Heaths (in several forms), *Cydonias* (in great variety), Jew's Mallow (single and double), Lilacs (in several varieties), *Berberis* (in great variety), *Magnolias*, *Cornus florida rubra*, the Snowdrop-tree (*Halesia tetraptera*), the Judas-tree (*Cercis Siliquastrum*), *Spiraeas* (various), *Viburnum rhytidophyllum*, *V. Carlesi*, *V. tomentosum*, *V. t. Mariesi*, *Amelanchier canadensis*, *Daphnes* (in variety), *Salix* (in variety), Sand Myrtle (*Leiophyllum buxifolium*), the Labrador Tea (*Ledum latifolium*), Native, American, and Japanese Cherries (in great variety), *Pyrus Malus* (in great variety), *Weigelas*, the Alpine and Mountain *Clematis*, the Pearl Bush (in variety), the Evergreen *Laburnum* (*Piptanthus nepalensis*), *Laburnum vulgare*, *Camelias* (in variety), *Rhododendrons* (in variety), *Azaleas* (in great variety), *Andromedas* (several), Rocky Mountain Bramble (*Rubus deliciosus*), *R. spectabilis*, *Ribes speciosum*, *Maples* (various), *Corylopsis* (in variety), Mexican Orange (*Choisya ternata*), *Coronillas*, the alpine White Beam (*Pyrus Chamæspilus*), *Wistaria sinensis* and its white form, Japanese Orange (*Egle sepiaria*), *Akebia quinata*, *A. lobata*, *Kalmia glauca*, *Periwinkles*, *Griselinia littoralis*, *Elæagnus edulis*, Hawthorn, Siberian Pea-tree (*Caragana arborescens pendula*), *Azalea amœna*, *Narcissi* (in variety), *Honesty*, *Scilla campanulata* and its rose-pink form, Grape Hyacinths, *Cornus canadensis*, Star of Bethlehem (*Ornithogalum*) (in variety), the scarlet Windflower, the white, blue, and yellow Wood Anemones, *Anemone sulphurea*, *Megaseas* (various), Solomon's Seal, *Polyanthes* (in variety), *Auriculas* (in variety), late-flowering Tulips (in variety), *Anclusa myosotidiflora*, *A. Barrelieri*, *Viola cornuta* and its white variety, *Antennaria tomentosa rubra*, *Dianthus deltoides rubra*, Thrift (*Armeria*) (various), Wood Lilies (*Trillium*) (in variety), *Asphodelus luteus*, *Geums* (several), Tufted Pansies (in great variety), Bleeding Heart, Alpine Phlox (in great variety), Blue-eyed Mary (*Omphalodes verna* and its white form), *Oxalis*, *Lithospermum prostratum* and its Heavenly-blue variety, *L. purpureo-cæruleum*, *Iris germanica* (in variety), *Helichrysum bellidoides*, *H. trinerve*, *Jonquils*, *Meconosopsis sinuata latifolia*, *M. cambrica*, *Calthas* (in variety), Globe Flowers (in variety), *Gentianas* (in variety), the Foam Flower (*Tiarella cordifolia*), *Romanzoffia sitchensis*, Sun Roses (*Helianthemum*) (in variety), *Ranunculus speciosus*, fl.-pl., *Mazus rugosus*, *Luchnis diurna*, *Alpine Achilleas*, Summer Snowflake, *Kenilworth Ivy*, *Ethionema persicum*, *E. schizotomum*, *Pentstemon Scouleri*, *Gypsophila prostrata alba*, *Cytisus Ardoini*, *Saponaria ocymoides*, *Houstonia cærulea*, *Cheiranthus linifolius*, Iceland Poppies, *Pæonia officinalis*, *Rheum officinale*, *Doronicum*, and *Saxifraga peltata*.

WORK OF THE WEEK.—The alpine plants on raised borders are now very interesting, many of them being already in bloom. Old, disfigured foliage has been cut away and the surface soil loosened up wherever possible to promote a free, healthy growth. Very small plants have had a couple of flat stones placed round them as a protection, and large, encroaching kinds have been cut back severely. A bed of yellow Roses has been carpeted with *Cynoglossum amabile*, and *Monroe's Mallow* has been planted to form an edging to another bed where it may fall over stones raised above the ground level. A few plants of *Nierembergia frutescens* have been put out at the corner of a large bed, and *Arenaria montana*—perhaps one of the choicest alpinists—has been given a position where it can thread its way over sandstone blocks in the form of a wide and broken edging. A few more of the same plant have found a home on a raised bank in the foreground of *Azaleas*. A group of

Achusa italica has been carefully lifted and replanted to fill a gap in the hardy-flower border, and the plants are none the worse for their late shift. Several plants of the Transvaal Daisy (*Gerbera Jamesoni*) have been planted below the Californian Tree Poppy (*Romneya Coulteri*), using the little *Pistorinia hispanica* as a carpet to the whole bed. Clematises are now growing freely, and the alpine and mountain species are in bloom. A number of the old dark Antirrhinum has been put out to furnish one end of a long Rose bed. *Ethiopia Lamarckiana* has been used to form a wide line with lavender-coloured *Michaelmas Daisies* at intervals. These should provide a pretty autumn display.

Mowing occupies considerable time, as Grass grows very fast at this season of the year; the cutting of Grass edgings is also receiving attention, as this greatly improves the appearance of lawns and verges. During the recent storm a number of large spreading Yews was forced across a Grass path, and it became necessary to cut these back severely to allow light and air to reach the Grass and give a free passage. Hardening of vase plants and the removal to cold frames of such things as are required for the beds and borders are receiving constant attention. Cannas have been placed in cold frames, also Cardinal Lobelias, Verbenas, and a *Verbena*, Rose Queen, a beautiful variety which had been previously hardened off, has been planted as a groundwork to a bed of Roses, also as an edging. The charming variety Blue Bell is put out to form an edging to a bed of orange-scarlet Cannas, a few of the same *Verhena* being used as a groundwork to a column of pink Sweet Peas. E. M.

SOUTHERN COUNTIES.

Pentstemons.—These will be planted in their permanent positions. Being rather gross feeding, the soil needs to be made fairly rich. Each plant requires ample space for development, consequently the distance between them each way is 18 inches. A good soaking of water to settle them into place will be given as the planting proceeds.

Calceolarias.—These will also be planted where they are to flower, as frost likely to injure them need not be apprehended after this. Until they become established, the soil about the roots must be kept moist.

Agathæa cœlestis.—This, the so-called Blue Marguerite, is also fairly hardy, and can be planted without further delay. It is very useful as an edging to taller-growing subjects, and thrives equally as well in heavy soil as in that of a lighter and more friable nature.

Antirrhinums.—These have had the points pinched out to make them break and form bushy, shapely plants. Growth will now be rapid, and they will soon be ready for getting out into their summer quarters. The site has been manured and dug, and the soil is in good working order.

Fansies.—Seedlings which some weeks back were pricked off into boxes are now well hardened off and of the right size for planting out, the places selected for them being the margins of borders, etc., and the positions not too exposed, so that they may remain in good condition for as long a period as possible.

Marguerites.—As these pass out of flower indoors they are slightly cut back, and as soon as new growth is visible they are hardened off and planted in groups in suitable positions among shrubs and in flower borders, where they produce an abundance of bloom and prove very effective. Both the single and double varieties are equally valuable for the purpose.

Fuchsias.—Spare plants of these must now be hardened off to fit them for planting out towards the end of the month. Their value for the flower garden is well known, but they must not be planted in poor soil if they are required to look their best.

Other bedding plants.—Those of a more tender nature are now being exposed to the elements to get them thoroughly hardened by the last week in the month. The sashes are, however, kept handy in case a fall in the temperature should necessitate their use during the period between the 15th and 22nd, after which they will for this purpose be no longer required. The pots being full of roots, their requirements in the way of water are, and will be until they are planted, rather exacting, and take up a good deal of time, as supplies are needed twice daily in sunny weather.

Roses.—Both beds and borders will, with the idea of breaking the soil down to a fine condition, be thoroughly hoed through. When partly dry after rain is the best time to do this with the class of soil I have to deal with, as the rough lumps then crumble to pieces without an undue expenditure of labour. Roses are breaking strongly, and exhibit not the slightest sign of having experienced the check they did earlier in the year. Grubs must now be looked for, their presence being denoted by the rolled and twisted appearance of the leaves. A sharp pressure between thumb and forefinger is the simplest and most effective way of destroying them. Green-fly attacks quickly yield to one or two sprayings of *Quassia* extract. For mildew, which often appears now on Ramblers when exposed to cold easterly winds, there is no better remedy

than sulphur dredged over the leaves after they have been moistened. This can be washed off a day or so afterwards.

Plums.—These have set well, and if the fruit should swell off properly there will be a bountiful crop. Fortunately, the foliage has during the past few days developed to a remarkable degree, which will afford a great deal of protection should it be needed to the young and tender fruits. A sharp outlook now has to be kept on the young growths, which quickly become crippled should fly once gain a footing. Remedies should be applied directly its presence is detected, as an attack is much more easily dealt with when it is in the initial stage than when the leaves become curled and the insects difficult to dislodge.

Apricots.—In spite of the untoward weather encountered when the trees first came into bloom, a very good set of fruit, which is now fast swelling off, resulted. On some trees a slight thinning in the way of reducing "twins" and "triplets" to one is necessary, and accordingly will be attended to. Stopping and thinning of young growths also need attention, while a sharp look out for maggot must be kept, otherwise much of the foliage is liable to be damaged. After the unprecedented rainfall of March artificial watering will be unnecessary for some time to come. The nets may be rolled up out of the way and temporarily fastened on the top of the coping-boards to be ready for use in case of emergency, as it is not prudent to dispense with them altogether until near the end of the month.

Peaches and Nectarines.—Disbudding is being proceeded with, and, as in the case of Apricots where more than one fruit has set in one place, a reduction to one, and that the most promising, is being effected. A tentative thinning of the fruit where several are present on individual shoots is also having attention, as it is a waste of energy to allow too great a number to develop unnecessarily. The person carrying out these details should have a powder-puff, so that in the event of any fly being discovered they can at once be destroyed. As soon as settled warm weather sets in the trees will be well washed, which will not only cleanse and refresh the foliage, but wash off the remains of the flowers on the fast swelling fruit. The netting can now be fastened out of the way as for Apricots, so that sunlight and air can have free play amongst the foliage, and accelerate growth.

Asparagus.—With the advent of warmer weather Asparagus has become plentiful and of excellent quality. Such being the case, the usual practice of sorting the produce into three sizes is resorted to, the smallest, or "sprue," being used for soups. A dressing of fish guano will now stimulate growth. Enough to just colour the soil is sufficient to give at any one time. Weeds are already appearing, and call for attention in the way of hand-picking, which, under the circumstances, is the only practical way of dealing with them.

Potatoes.—The late sorts are now being planted, horse labour being employed for the preparation of the soil and the opening and closing of the drills. Early and second-early sorts being now well above ground, the soil between the rows has been loosened and moulding carried out.

Hoing.—Onions, Parsnips, Carrots, and other crops have had the soil hoed between the rows for the twofold purpose of expediting growth and killing weeds, which, unfortunately, promise to be unusually abundant.

Late Seakale.—This is now over, and the crowns must be cut off level with the soil to induce the formation of new growths. When fairly started growing, feeding with artificial manure may be commenced. The material recently used for the blanching of the Kale will be formed into long ridges between the rows, where it will be out of the way and ready for use next season. A. W.

MIDLAND COUNTIES.

Wall trees.—The training of the young growths requires almost daily attention during the present and four following months. Peach and Morello Cherry-trees, owing to the multitude of young growths require prompt and frequent attention during the period of growth, the treatment being identical in each case. After a sufficient number of the current year's shoots has been laid in for producing fruit next year all surplus shoots, together with fore-right growths, must be kept pinched (and in some cases rubbed off) to within one joint of their origin. Very strong growths should be cut back to the lowest lateral or removed, in order to direct the flow of sap into the weaker ones. Apricot, Plum, and Pear trees also require the same treatment as regards the training in of young growths at regular intervals over the available wall-space and for the purpose described above. Care should be taken to keep all kinds of fruit-trees free from the attacks of aphid and red spider by a vigorous, timely, and well-directed washing of the trees, using clean water applied to the trees through the garden-engine or syringe, in addition to keeping the soil about the roots uniformly moist. Should this fail, recourse must then be had to insecticides.

The Codlin Moth.—Where this insect pest is prevalent means should be taken to destroy it at this season, the best time for applying an

insecticide being immediately after the petals have fallen and the fruits are set. Paris green distributed by means of a sprayer in the proportion of 2 oz. to 18 gallons of water makes an effectual dressing. As this is a very poisonous substance great care is necessary in its use. The powder does not dissolve in water, but is merely held in suspension, and it is, therefore, necessary to keep it frequently stirred. Where American blight is detected the patches should be dabbed over with a stiff brush dipped in petroleum or methylated spirit, repeating the operation at intervals during the season.

Gooseberries are particularly liable at this season of the year to attacks of various sorts of caterpillars, which denude them of their foliage and render the fruit useless; the Gooseberry caterpillar and the larvæ of the Gooseberry and Currant sawfly being the worst. Their mode of operation, their appearance, and time of attack are quite different, but the results to the bushes are very similar, and if not checked the plants soon present a miserable appearance, the leaves being riddled with holes in all directions. The most effectual remedy is to destroy them in the pupa state while in the soil underneath the bushes by removing the surface soil to a depth of 3 inches and burning it, replacing it with fresh soil and a good dressing of soot and lime. Where bushes are attacked, the most effectual remedy at this season is hand-picking. Where large breadths are affected, the leaves should be dusted when moist with Hellebore powder, soot, lime, or other noxious applications that will make the bushes distasteful to the moths. After applying Hellebore powder great care must be taken not to use any of the green fruits until they have been thoroughly cleansed by rain.

Herbaceous plants.—Varieties of *Pœonia* Moutan in sheltered places will shortly be in flower, but the severe frosts, after they were well in bud, destroyed many shoots, the flower-stems completely shrivelling up. The early herbaceous varieties suffered to a less extent. Late-flowering varieties may be relieved of some of the small flower-buds if large blooms are desired; if not, these buds open later, and so form a slight succession, although the flowers are smaller. A good soaking of liquid manure is of much assistance to established clumps of these *Pœonies*. Delphiniums require staking before they become long enough to fall over and so grow out of shape. Many other subjects in the herbaceous borders now require short stakes and ties. During favourable weather keep all borders well hoed.

Annuals sown early and pricked out into frames and boxes are now being planted in their permanent quarters, choosing showery weather for the purpose if possible. Should the weather be dry at the time of planting, the young plants are damped overhead for a few days, this encouraging a free start. A little extra trouble taken at first is amply repaid by their quick and rapid growth. It is yet too early to plant out many of the more tender plants, such as *Heliotropes*, which are far better left where they can be afforded shelter in case of cold winds or frosty nights. Plants put out too soon often receive a check, from which it takes them a long time to recover. Most of the *Narcissi* and other bulbs have passed out of flower, and the present is a suitable time for marking such as need to be taken up when the foliage is ripe, divided, and replanted in a fresh place. This is necessary in many places in from three to five years. Do not cut off any green leaves, as this impoverishes the bulbs.

Chrysanthemums in pots.—The weather, until now, has scarcely been favourable for placing *Chrysanthemums* in their summer quarters out of doors, but this must be done at the first favourable opportunity or their shoots will become weak. The compost for potting these plants into their flowering pots will now be prepared. This will consist of three parts good fibrous loam in a lumpy state, one part of finely-sifted horse-manure, well-decayed leaf-soil finely sifted, and sufficient coarse sand and finely-broken mortar-rubble to render it porous, adding to every two bushels of the compost one 6-inch potful each of 2-inch bones, a suitable artificial manure, and finely-crushed charcoal. The strength of the plants will determine the size of pots to be used, but generally 8-inch to 9-inch pots are large enough. These must be clean and well drained, and on the top of the crocks a few 2-inch bones are sprinkled. Pot firmly, and, in doing so, place the top of the old ball well below the surface of the new soil.

Globe Artichokes have been examined and the suckers thinned to four or five on each plant, this number being quite sufficient to ensure the best results. The ground between the plants is mulched with a few inches of manure. It is a good plan to mulch the ground between the rows of many garden crops as soon as dry weather sets in, in order to counteract the effects of strong sun on the soil and secure a more equable state of moisture about the roots. Peas and Scarlet Runners benefit greatly by this treatment in dry weather, and even in wet weather, for it is much better for the soil that, while gathering the crops on wet days, there should be a covering of some kind to keep it from injury by continual treading.

French Beans sown on a warm border a few weeks ago are pushing through the soil, and

need protection at night. We continue to make small sowings on good ground every fortnight.

Potatoes.—The earliest plantings being now above ground, the young growths are protected by moulding well up, long litter or other material being applied when necessary.

Spinach.—Frequent sowings are now made of some of the Broad-leaved Long standing varieties, which are a great improvement on the older kinds, sowing at this season on a north border, or the coolest part of the garden on well-manured and deeply-worked soil. A small sowing of New Zealand Spinach should be made on a south border, unless it has been raised in boxes under glass, as previously advised, which is much the better way of treating this valuable vegetable. This variety, being very tender, should not be planted till quite the end of the month on a warm spot. Sprinkle overhead frequently to give it a good start. Use the Dutch hoe freely amongst all growing crops, for the double purpose of keeping the ground clean, and, by a loose surface, lessening the amount of evaporation during hot, dry weather. F. W. GALLOR.

SCOTLAND.

Late planting.—During the week a consignment of Butcher's Broom came to hand and was planted in various positions. The majority of the plants were of the female variety, although to make sure of berries a few pieces of the male variety were introduced. The plants were well furnished with plenty of fibrous roots, and although the season is somewhat advanced for planting, success is anticipated.

Plant-houses.—Owing to the removal out of doors for the purpose of hardening off, the congestion which always is present to some extent in plant-houses during spring has been considerably relieved. One house has been entirely filled with Zonal Pelargoniums and double-flowering Begonias. These plants, not being wanted for some time, will, in the meantime, be denuded of their buds as they appear. This results in a much more vigorous growth than would otherwise be the case, and the season of blooming is prolonged almost until the time when the house is again required for Chrysanthemums. Most of these Pelargoniums and Begonias are in 6-inch and 7-inch pots, but any particularly promising pieces will ultimately be moved into 9-inch pots.

Primulas.—*P. sinensis*, *P. obconica*, and *P. malacoides*—having ceased to be effective have been discarded. Some good plants of *P. obconica* will be saved, planted out in cold-frames over the summer, and repotted during the autumn. Although the practice is not generally recommended, I have found that two-year-old plants of *P. obconica* are always worth having. They flower profusely, and make good specimens in 8-inch pots. *Schizanthus Wisetonensis* has been very useful. Cut in long sprays, the blooms lasted exceptionally well in vases for over a fortnight, and were, for once in a way, free from the objectionable habit of drooping, which, for some reason or other, at times mars this useful and showy variety for cutting. *Hydrangeas*, both as bushes and on single stems, are yet being retarded as far as possible. Owing to circumstances the culture of Carnations under glass has been reduced, only the Malmaison family now being represented. In the course of the week these were staked out and top-dressed. In the stove a sharp drop of the outside temperature has led to rather brisker firing being necessary, but plenty of moisture is permitted in order to reduce the danger of attacks from insect pests. A batch of *Pentas carnea* was moved from 5-inch to 7-inch pots, and *Bryophyllum calycinum* and *B. crenatum* were similarly treated. Cuttings, now rooted, of various things, were potted off from the propagating-pit. These included a considerable number of Lorraine and other winter-flowering Begonias. *Libonia floribunda* is now in 4-inch pots. A quantity of this useful, old, hard-wooded subject has been propagated and will be used freely, not only for winter-blooming in the stove, but for spring work in the greenhouse.

Chrysanthemums.—A beginning has been made with the final potting up of Chrysanthemums. It is, of course, hardly the orthodox time, but in the present conditions it has been decided to dispense with the intermediate shift and to place them in their flowering pots straight away. This will call for careful watering for a time, but, given that, there does not seem to be any reason why they should not succeed. As potting is done, the plants are placed in a sunny, but sheltered, place, where they will remain until growth is somewhat advanced, after which they will be moved to their summer quarters.

Tomatoes.—With the exception of a few plants, the necessary quantity of Tomatoes for pots has been selected. Pots 10 inches in diameter are used, and in these the plants fruit satisfactorily. When the soil is moderately moist at the time of potting it is not considered necessary to water for a few days. All side shoots are regularly suppressed, although I have at times taken up a supplementary shoot from the base of a plant with very good results.

Hardy fruits on walls.—We are passing through rather a critical time in respect of the wall fruit. After a period of fairly good weather the temperature has dropped very

suddenly, and this drop has been accompanied by bitter east winds and by heavy rain, which at the time of writing has fallen almost incessantly for three days. These factors combined render the outlook none too bright. Peas and Plums, although fairly well set, are bound to suffer to some extent, and there is a likelihood of blister upon Peaches and Nectarines. Apples will probably escape should the weather shortly revert to the normal, for the cold snap has delayed the expansion of the blooms. Meantime, in the most exposed situations temporary expedients in the way of providing shelter have been resorted to. Damsons in the open appear to have suffered considerably from the wind and rain. The trees are of great age, very high, and are exposed to the full sweep of the east wind. Many of the blooms are entirely knocked off, and the outlook is far from encouraging at present.

Herbs.—In the beginning of the week fresh beds of Mint, Basil, and Marjoram were made. These are always in request, and new beds from time to time are necessary. All three being of a quick, not to say rampant, growth, soon come into use.

Vegetable garden.—With the breakdown of the weather, work among vegetables was greatly curtailed. Nevertheless, in the early part of the week some little progress was made. Pea-staking was attended to, and a further line of Peas was sown, Telegraph being the variety used. Lettuces were transplanted, others pricked off, and more seed sown.

Grass-cutting for the first time has been done at a later date than usual. In some places the scythe had to be used, but, fortunately, all the Grass had been gone over before the rain had made the ground too soft. W. McGURROG.

Balmac Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Violet flowers failing to develop (Winton).—The most probable cause, if we may judge from the shrivelled up flowers you send us, is lack of moisture. If so, then the natural result will be that the flowers will not and cannot develop properly. If on examination you find that the soil is dry, then the remedy is in your own hands. We should like to see a complete plant.

Growing Watsonias (Inquirer).—Treatment similar to that required for the early-flowering Gladioli suits these. If they are grown in frames a good deal of trouble is saved and the flowers are finer, as the young growths are protected when they most need it. Generally, however, it will be found best to grow the plants in warm situations in open borders of light soil.

Procuring Primula cashmiriana seeds (H. M. Darrah).—It is highly probable that if you write to any of the firms named in your letter they would be able either to supply you at once, or, failing this, to send seeds a little later on when mature. If not, you might write to those nurserymen who specialise in hardy plants, and whose names you will find in our reports of the Royal Horticultural Society's meetings. In addition, your own plant, assuming that it has flowered well, should yield you a nice supply, which, if sown soon after ripening, should furnish a considerable number of young plants in the coming year.

Various queries (M. W.).—(1) Had you left the bulbs where growing and lifted them when the foliage had ripened off, then it is very probable that many of them would have flowered this year. The bulbs were never properly ripened off, hence the failure to bloom. (2) The *Spiræas* have evidently suffered from want of water. To do these well they must be stood in pans of water when growing freely. (3) Dryness at the roots was, no doubt, the cause of the flower-buds falling. The soil on the surface may have looked moist enough, but the ball of soil was, no doubt, dry. The only way to remedy this is to stand the plant in a pail of water and thus soak the ball right through.

Treatment of Gerberas (Mrs. K. Clark).—Even in the most favourable districts the Gerbera must be planted in a sheltered, warm place, such as at the foot of a wall. In very sunny quarters in the southern parts of the country it has passed through several winters unimpaired. In the Cambridge Botanic Gardens it thrives at the foot of a wall, protected during the winter by lights from rains and cold dews, while allowing full ventilation on every side. A well-drained spot and shelter are essential to success. Though it will bloom fairly well in pots, its progress is slow. You must be careful not to overpot or overwater. A good compost for it would be a free loam to which have been added some decayed leaf-mould and plenty of silver sand.

MISCELLANEOUS.

Making liquid-manure (L.).—In the absence of cow-manure an excellent stimulant can be made from soot. Put about a couple of pecks in a canvas bag, tie it up tightly, and fix a brick or stone to it to cause it to sink, and then immerse it in a tub of water containing eight to ten gallons. After a time the bag

should be squeezed to extract the goodness from the soot, and then the water should be allowed to settle before using. It should be given in a diluted state, say two quarts of the liquor to a gallon and a half of clear water. By similar treatment another excellent manure can be made from fresh horse or sheep droppings.

SHORT REPLIES.

Francis Chown.—See reply in coming issue to "F. M. G." re "Vine leaves scalded."—*M. Fimc.*—No; we have never heard of *P. malacoides* being poisonous, as sometimes happens in the case of *P. obconica*.—*Ivywell.*—Any of the Rambler Roses will answer.—*E. C. B.*—Yes; you may put in cuttings of *Heliotrope*, but if you want them for the flower garden this season they will be of no use, and should be grown on freely in pots to bloom through the autumn and winter. The best *Primula* for your purpose is *P. obconica*, seed of which may be sown now. The seedlings, if grown on in a mixture of loam, leaf-mould, and sand, will flower in the autumn and through the winter. They should be potted into 5-inch or 6-inch pots, in which they will flower.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*M. D.*—The white Wood Lily (*Trillium grandiflorum*).—*Robert Greening.*—*Populus canadensis*.—*Evelyn G. Smith.*—*Geranium tuberosum*, a hardy variety from the south of Europe, flowering in May, colour of flowers pink. It was introduced in 1596.—*E. C. B.*—1, *Begonia Dregei*. OBITUARY.

PHILIP MOON.

We greatly regret to record the death at the front, through the explosion of a mine, of Philip Moon, son of the late Henry Moon, the best flower painter of our day. Philip Moon inherited the love for natural beauty of his father, and began to collect plants at a very early age. The letter following is from his mother:—

You will, I know, be sorry to hear the news of my son's death at the front on April 28th by mine explosion. His captain writes me:—"Philip was a brave soldier and a good lad—one of the very best—and he had for a long time had our admiration and love. I will always treasure the memory of him. His great love of Nature and his knowledge of flowers were so wonderful to us all." The chaplain has also written me, and I am a proud mother to have a son who, in his short life (nineteen years), has left such a record for good.

A register of girls and women in West Hoathly and Sharpthorne who are willing to work on the land has just been started. Any employer who requires workers is invited to write to Mrs. F. Jenner, North Lane, West Hoathly, or call at her house between 6 p.m. and 8 p.m. on Fridays. No fee is charged for this patriotic organisation; conditions of work and rates of pay to be arranged direct between employers and workers.—*JULIA M. COHEN, SOPHIA POWELL.*

PORTABLE WOOD BUILDINGS.

Substantially constructed in sections, to screw together. Framework of good well-seasoned timbers, covered with best tongued and grooved matchboards. Roof is of strong timbers, covered with tongued and grooved boards, and compressed sheet-roofing felt. Door, complete with lock and key, in end or side. Windows in any position desired. Floors on strong joists are quoted extra. Necessary bolts and screws, everything complete.

7ft. by 5ft., £113s. 6d.; 8ft. by 6ft., £57s. 3d.; 10ft. by 7ft., £617s. 6d.; 12ft. by 8ft., £93s. 6d.; 15ft. by 9ft., £127s. 6d.; 16ft. by 10ft., £121s. 2s. 6d.; 20ft. by 12ft., £221s.; 30ft. by 14ft., £3517s. 6d.

PORTABLE STABLE, COACH AND HARNESS HOUSE.

Suitable for 1 pony and trap, 14ft. by 10ft., £1417s.; for 1 horse and trap, 15ft. by 12ft., £195s.; 2 horses and trap, 20ft. by 12ft., £2510s.

THEORY v. PRACTICE.

[To the Editor of GARDENING ILLUSTRATED.]

SIR,—I have read with interest the articles in your April numbers of GARDENING ILLUSTRATED on "College Education versus Practical Training in Horticulture." With regard to the appointments of park superintendents and other branches being political, I do not think this condition exists so much in Canada. Most of the positions are filled by young men who have graduated from one of the agricultural colleges, which endeavour, as far as possible, to also give a practical training that will meet the requirements of a new country. I would be loth, however, to advise a practical gardener that he could do well in Canada. I know of several good men, with excellent records in various branches of horticulture, that are working at ordinary manual labour. There are very few establishments where you would meet with the variety of plants or shrubs that one sees in any ordinary English garden. I believe if practical men who had a genuine love of their profession—as most of them have—were appointed they would soon create more interest in the varied branches of gardening, both with the employers and the public. The only branch of the profession that is taken up extensively at present is fruit-growing, which is certainly rather overdone in British Columbia, although most of the failures in this branch can be traced to orchards being managed by inexperienced men who, not being practical, have been unable to adapt themselves to the various climatic and other conditions which exist in this province. I have had a life experience, gained at some of the leading establishments in England and Scotland, but have been obliged to take up another line of business, as I found it impossible to make even a living in horticultural work. The best gardens and parks in the eastern States of America were laid out and managed by Old Country gardeners who had served their apprenticeship in the profession, and who worked as journeymen at various places before taking charge. It is hard to beat a practical British gardener, no matter what adverse conditions exist, or in what part of the globe he may be. If the home settlement scheme of Sir Harry Verney's Committee, which was reported in *The Times* of February 10th, and which proposes a grant of £2,000,000 for this pur-

pose, comes into force, the Board of Agriculture should see that practical horticultural and agricultural instructors and directors are appointed for this work if it is to be a success. H. W. W.
Kettle Valley, British Columbia.

NOTES OF THE WEEK.

Cheiranthus linifolius.—A pretty little Stock with soft mauve flowers and narrow leaves. A distinct and good rock plant, native of Spain and Portugal. From Clarence Elliott, Stevenage.

The Alpine Flax (*Linum alpinum*).—In these days of love for rock gardening this should be often seen. Its dwarfness makes it quite distinct from the herbaceous Flaxes of our gardens. The flowers are delicate azure-blue, the plant spreading, and quite hardy. From Sir F. Crisp.

Narcissus Johnstoni Queen of Spain.—In the Grass this is one of the sweetest things we know, and those who are taking up this phase of gardening should plant it, as bulbs can now be obtained very cheaply. There is a quaintness in the reflexing perianth and nodding flowers that renders this kind distinct from all else.

Pæonia Delavayi.—A graceful, free, and distinct kind, with handsome foliage and dark, rich flowers, tempting one to make a group of it as soon as plentiful. The old tree Pæonies are, owing to grafting and climate, a weariness to the flesh. This promises to be a free and useful kind. From Bees, Liverpool.

Lewisia Howelli.—This, one of the best of the genus, has stood the winter in some south-west of Scotland gardens and is coming into bloom. Mr. James Davidson, Summerville, Maxwelltown, has a specially good plant in full bloom in the rock garden. Its handsome rosette of leaves, even when not in bloom, is pretty.—S. A.

Rhododendron decorum.—This noble Rhododendron is in fine flower now (May 21st) on young seedling bushes. An old bush withstood our winters for many years, and usually flowered in early autumn, after all the other kinds had passed. There seems some variety as to time of flowering in this lovely plant of Western China.—W.

Phyllothamnus (syn. Bryanthus) erectus is again in flower in a peat bed at the base of the rock garden. Its bright pink, Kalmia-like flowers show up well on the dark, rigid foliage. It was obtained by

the late Mr. James Cunningham, of Comely Bank Nurseries, Edinburgh, by crossing *Menziesia cœrulea* and *Rhododendron* (*Rhododendron*) *Chamaecistus*. It grows only a few inches high and is evergreen.—S. ARNOTT.

Myrsine africana.—A myrtle-like little bush, native of many lands, some tropical, and yet hardy in our islands, the fruit purplish. It is an interesting rock garden shrub and is now fruiting freely at Nymans (Sussex).

Lilium myriophyllum.—This is a tall and most graceful Lily, white, with the outside of the flower suffused and striped with dull purple, the centre a yellow basin. Like other Lilies, it will be at its best among shrubs in peaty or leafy soils. From Messrs. Wallace and Co., Colchester.

A brilliant Sun Rose (*Helianthemum Chamaecistus*).—In the belief that I had enjoyed all the beauty of these plants I was shy of adding to them, but now have to record the brightest of all, sent me by Messrs. J. Waterer, Sons, and Crisp, of Bagshot. It is a lovely red with a little bunch of yellow stamens, and is quite hardy and free to bloom grown in a raised border.—W.

Acacia Baileyana.—The cold frosts in spring have been a hard trial for those in this country who like Acacias. I never had the courage to plant any. At Nymans, where they are done so well, and look very pretty in flower and leaf, they suffered a good deal, and the first to come out is that called *Baileyana*, which has the best chance of any against south walls in our country.—W.

Camellia cuspidata.—This is an elegant little evergreen bush, nearly allied to the Tea, and named *Thea cuspidata* by Koehs. The flowers are white and pretty and it is graceful in habit grown in the open air at Nymans. Should the Theas prove as hardy as the *Camellia* they will be a very interesting addition to our gardens. I saw several in Mr. Allard's garden at Angers, but I imagine our people have not got them yet.—W.

Rhododendron Roylei.—It is interesting to note that the frost which nipped so many things in the spring after a number of warm days has not had much effect on the Himalayan Rhododendrons. I was amazed at the beauty of *R. Roylei* the other day at Nymans, where it was covered with flowers and looking as hardy as a native bush. The colour of this Rhododendron is very beautiful and its

habit fine. The soil of the place is not in favour of such plants, but with the aid of leaf-soil and other decay of the woods it evidently had the conditions that suited it.—W.

Phlox Douglasi.—The dwarf mountain Phloxes are usually easily grown, but this very dwarf kind is not so free with me. Its soft pink flowers are charming, and it is well worth a place on the choicest rock garden. From seed, and in warm soil, it may be more free. As I saw this dwarf Phlox on the Rocky Mountains it grew among the débris of the rocks.—W.

The Siberian Pea Tree (*Caragana arborescens*).—The Caraganas are not attractive shrubs, partly due to the dullness of their flowers, but the above is pretty now, its small, yellow, pea-shaped flowers, borne freely from among the fresh, soft, green foliage. It is of pendulous habit of growth, and for this reason is usually grafted 6 feet or so from the ground, on what appear to be *Laburnum* stocks. With me it is slow growing, and therefore can be planted where space is limited, or if obtainable on its own roots it might be planted to fall over a large boulder in the rock garden. There are several other forms, but this is the best known in gardens.—E. M.

The Norway Spruce, an over-planted tree.—Sir Herbert Maxwell condemns this in the *Gardeners' Chronicle*:—

Even in such highly-favoured situations as the valley of the Tay at Dunkeld, where the Common Spruce may be seen at its best, better and cleaner timber might have been obtained if certain other species of Conifer had been planted. Unfortunately, in the haphazard, indiscriminate fashion of mixed planting which has prevailed for nearly a century in the greater part of northern England and Scotland, the Common Spruce has been, and is, an almost invariable ingredient, with such miserable result as may be seen, especially in districts near the sea.

Shortia galacifolia.—For a great many years there has been a very fine specimen of *Shortia galacifolia* growing like a parasite among the roots of a dwarf Conifer, called, I think, *Pinus beuvronensis*. Great numbers of flowers are produced from February to April. This spring I counted over a hundred. I have always wondered that no seedlings have ever appeared. Last year I saw a plant which I thought might be an offset at some distance from the parent, but this was evidently not the case, as it was on the further side of a large mass of natural rock. To-day (May 21st) I was delighted to see two flowers open. Can anyone tell me whether *Shortia* seedlings are uncommon in this country?—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed*.

Crokia Cotoneaster.—Although this New Zealand evergreen shrub was introduced forty years ago it is not very common, possibly by reason of its being tender when grown in the open. In many gardens in the south and west counties it may be expected to thrive in the open, whilst elsewhere it can be grown against a sunny wall on which it grows fast, attaining a height of 10 feet or 12 feet, with a similar spread. During April and May a generous display of star-like golden blossoms is developed. When grown in the open it forms a bush 6 feet or so high with a dense mass of wiry, tangled branchlets, and if in a sunny position blooms freely. Small orange-red fruits are sometimes produced, but rarely in sufficient numbers to be very noticeable. Cuttings of short shoots

root well in a close frame in summer. Plants grown against walls require a little annual pruning after flowering to keep them near the wall, but bushes grown in the open are best left unpruned.—D.

Rhododendron yunnanense.—This is a very beautiful, light-growing species of rather an open and airy habit and good in effect. When it was first sent to me by M. Maurice de Vilmorin it interested me, but not so much as when seen fully grown. It is not easy to judge the value of a garden plant from a little spray in the hand or a bud of any kind. In spite of the nip of frost after the recent rains, which killed so many plants, this has not been touched in the least where it is, and is a mass of beautiful flowers.—W.

A note from Nenagh, Co. Tipperary.—A Holly at Rockford, still in fruit (May 19th), has a very fine appearance, especially when seen from some distance. Although other crops suffer greatly from the attacks of birds, this Holly has escaped. A Chrysanthemum which, in the natural course of events should have bloomed in mid-winter, but which was kept dwarf and prevented from flowering, is now bearing three good blooms in the conservatory. Strawberries, Raspberries, and Black Currants give good promise, but the prospect of the Apple and Pear crop is not so bright. The attention given to the Apple is increasing, but in Ireland we have yet to make great advances in fruit culture if we are to achieve anything like reasonable success. It is useless trying to reclaim old, worn-out trees that have lived through many years without attention. In many places, especially in the south of Ireland, old and useless trees are retained when their places could be profitably filled by young, healthy trees, which, given attention, would soon repay the small cost entailed. In some districts large areas are planted, but in many cases there is evidence of want of skill in the pruning. The trees, to produce the best results, must have skilled treatment of root and branch.—D. HANNIGAN.

The English Bluebell.—A few years ago a friend of mine living in this neighbourhood discovered in one of his woods a buff-coloured variety (*lutea*) of this very well-known and generally abundant flower, *Scilla nutans* or *S. festalis*. This induced me to ransack a large number of woods round here, but the results have not been very remarkable. The small white form, *alba*, is quite common; *alba major* considerably scarcer. One of a pale lilac tint (*ilacina*) is of frequent occurrence, so is a large blue (*Leonidas*), whilst of a small-growing, whitish-rosy form (*albo-rosea*) I have only found two plants, and four only (all in one group) of a tall, dark purple tint (*atropurpurea*). The above varietal names, except *alba*, *alba major*, and *Leonidas*, I have invented simply for the convenience of labelling, and I cannot help thinking that this is the only satisfactory, not to say scientific, way of studying any given species. The works on English Botany, to which I have reference, seem lamentably deficient in this respect, but one gets more help from nurserymen's catalogues. Van Tubergen, for instance, catalogues these additional varieties, most of which I grow, viz., *delicata* (white, shaded blue), *Blush Queen* (fine pale rose), *Robin Hood* (pale rose, red-tipped, large spikes), *rosea* (rose), *rosea major* (very large, rosy), and *rubra* (lilac-red). A group of these, grown in clumps of about a dozen bulbs, is a most entrancing sight and full of the deepest interest.—G. H. RAYNOR, *Hazeleigh Rectory, Essex*.

PLANTS AND FLOWERS.

INDOOR PLANTS.

FUCHSIAS.

THE recent note in these pages on Fuchsias in the flower garden serves to remind one of the many uses to which, from their accommodating nature, they may be put. They may be employed in various ways for the embellishment of the greenhouse or conservatory. They are grown in immense numbers as dwarf bushes in pots from 5 inches in diameter upwards, and if carefully attended to as to watering, with an occasional stimulant, they will bloom over a lengthened period. They may be grown as pyramids, in which form they used to be very popular, especially in the west of England. Now that standards are much appreciated there is nothing better for that mode of culture than Fuchsias of different sorts, as owing to the pendulous nature of their blossoms they are seen to very great advantage when grown in this way. Large specimens, either in pots or tubs, are well suited for balconies or terraces during the summer. Again, in the greenhouse the looser-habited varieties are very showy when trained to the roof, as under favourable conditions they will form a veritable canopy of drooping blossoms. The same feature stands them in good stead when employed for hanging baskets, for which purpose, apart from the garden varieties, one species is particularly suited—*Fuchsia procumbens*—a slender, creeping plant. For window-boxes, too, Fuchsias are well adapted, their graceful habit being then well seen, especially if they are not too much crowded together. When grown in this way it is very essential that the plants are not allowed to suffer from want of water, as from their sometimes elevated positions they are much exposed to drying winds. An occasional stimulant during the season is also of great service in prolonging the display of bloom. The relative merits of single and double flowers in the case of the Fuchsia are sometimes a matter for controversy. I much prefer the varieties with single blossoms, for though the large, double flowers are very striking they have a lumpiness which we do not find among the singles. In any case the varieties with single flowers are best suited for the outdoor garden, as in rough winds the heavy blossoms are far more liable to suffer than the lighter ones.

HARDY FUCHSIAS are, in many cases at least, not appreciated to the extent they might be, for during the latter part of the summer they are delightful. The well-known *F. Riccartoni*, which forms such a striking feature in many places around our coasts, is one of the hardiest and most vigorous, but there are many other valuable kinds. W. T.

NOTES AND REPLIES.

Luculia gratissima.—There is a difference of opinion as to the best way of growing this plant. Some maintain that success will not follow unless it be planted out and trained on a wall, others holding that it will succeed perfectly well as a pot plant. *Luculia gratissima* can be grown either way; the details in either case being but slightly different. When planted out, the larger root-run makes for finer plants, but insects are much more difficult to keep down, owing to the impossibility of using the syringe at the back of the plant where the shoots are secured to the wall. This drawback is not present in the case of plants grown in pots, these being easily kept clean and in good health. A little closer pruning is necessary than is the case with plants on wall or

trellis; and the best time to do this is immediately after flowering is past. Let the roots be fairly dry before pruning takes place, and but little moisture will be needed till the plant is again on the move. A warm, rather moist greenhouse temperature suits it well and the soil should be rather free and not too rich. Good loam, a few pieces of charcoal, with some leaf-mould and plenty of sand, will suffice. *L. gratissima* is, in my experience, one of the most difficult hard-wooded plants to strike.—K. BRIGHT.

Pelargonium ardens.—Some of the true species of *Pelargonium*, and the hybrids once removed therefrom, are remarkably pretty and more interesting than the innumerable garden forms. One such is *P. ardens*, which forms a free-growing, freely-branched plant of a firm, woody

should be fully exposed to the sun. Cuttings are not at all difficult to root, but care must be taken that the soil is not kept too moist.—W. T.

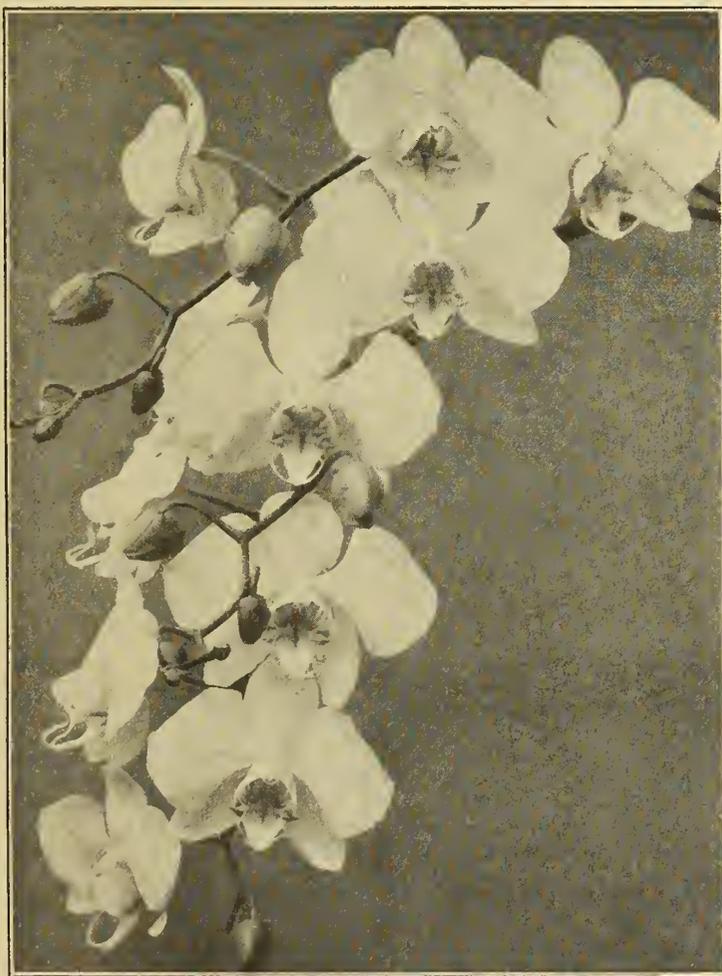

Impatiens Holsti.—Among the various Balsams that have been introduced within recent years this is one of the best for the greenhouse, as most of them require a somewhat warmer structure. This species is of sturdy growth, and the flowers, of a bright vermilion tint, are very freely borne. If the plants are assisted with an occasional stimulant a succession will be kept up for months. Propagation is readily effected by means of cuttings or seeds. Several forms with flowers of different colours have been distributed, but I prefer the typical kind. A more recent species somewhat in the same way is *Impatiens Herzogi*, in which the flowers

gestive of those of a *Bouvardia*, and bright red in colour. A group of well-grown plants forms a very attractive summer feature in the greenhouse. In a sunny structure seeds from which young plants can be raised may be ripened, while cuttings of the shoots or even single leaves will root without difficulty. From their succulent nature care must be taken that they do not get too wet. There are numerous other species, and several hybrids have been raised, but none of them is likely to obtain the popularity of *Kalanchoe flammea*. The tall-growing *K. Dyeri*, with large white blossoms, is valuable from the fact that it flowers in the winter and early spring months.—W. T.

The Pine-apple-scented Sage (*Salvia rutilans*).—Cuttings of *S. rutilans* will now strike readily without bottom-heat; and, when rooted and hardened off, the plants may be put out in a bed until September. If then lifted and potted they make fine specimens for greenhouse decoration during winter, and many who do not care for the stiffer, but more gorgeous, *S. splendens* might appreciate this variety with its delicately-perfumed foliage and its spikes of graceful tubular coral-pink blooms.—KIRK.

Viburnum macrocephalum for the conservatory.—This makes an excellent wall plant in this country, its monster cymes of pure white flowers being very effective in the month of June. I desire, however, to recommend it for conservatory decoration, where it can either be planted out and trained against a wall or it can be grown in standard form in a large pot. Treated thus it will flower during March and April.—ALBION.

Achimenes.—Like many other plants, *Achimenes* appear to have lost much of their former popularity. There is a general idea that unless considerable heat can be afforded, it is idle to attempt their cultivation. This is a mistake, for if they can be given the assistance of a mild bottom-heat the corms will readily start into growth and afterwards succeed under ordinary greenhouse conditions. *Achimenes* are especially adapted for baskets.—KIRK.

Phalaenopsis amabilis.

texture, and flowers throughout the entire summer. The blossoms, borne in fair-sized clusters, are of a rich scarlet colour, with almost black shading in the centre. A species seldom seen is *P. echinatum*, whose stems are very stout and furnished with spine-like stipules. The lower portion of the stem is, as a rule, devoid of leaves, and the roots are of quite a succulent nature. Although not so continuous blooming as the preceding, *P. echinatum* is remarkably pretty when in flower. The blossoms, borne in loose clusters, are of a clear white, with a dark red spot on the upper petals. Some varieties were put into commerce several years ago in which the flowers are pink or purplish, but I prefer the original species. From its half-succulent nature *P. echinatum* needs to be carefully watered during the summer. In the autumn it

are considerably larger and of a kind of orange-salmon colour. To be seen at its best it needs more heat than the preceding. A very old species, but withal a good one, is *I. Sultani*, with rose-coloured blossoms. Of this there are forms which vary in the tints of the flowers. One of the showiest species is *Impatiens Hawkeri*, but it is so liable to the attacks of a kind of mite that it is rarely seen in good condition.—K. R. W.

Kalanchoe flammea.—Few greenhouse plants have made such rapid advance in popular favour as this, introduced nearly twenty years ago. This is not to be wondered at, as it is readily propagated, of simple cultural requirements, and will flower for a long time. It is of a succulent nature. The flattened flower-head is composed of a great number of blossoms, which individually are a good deal sug-

ORCHIDS.
PHALÆNOPSIS AMABILIS.
This is a native of the Philippine Islands, and was first introduced into this country in 1837. The plant, when well grown, produces flowers in great profusion, and which, in a suitable atmosphere, last a long time in good condition. The sepals and petals are pure white, the lip also white, but spotted with purple, and with a yellow stain on each side. The plant grows naturally in an atmosphere that is nearly always at saturation point, and this should be imitated as nearly as possible. The best position for it is on the shady side of an ordinary plant stove, but where a separate house is provided for the cultivation of *Phalaenopsis* there is no difficulty in providing a suitable temperature. The varieties of *Phalaenopsis* usually commence growing in March or April, and a temperature ranging from 70 degs. to 80 degs., according to the weather outside, should be maintained until November, from which time till the growing season again commences the temperature should be between 60 degs. and 70 degs. The plants may be grown in pots, shallow pans, Teak-wood baskets, or cylinders, which should be well drained. The plant should be placed in the centre, spreading the roots out, and working in between them some clean Sphagnum Moss and finely-broken crocks, pressing it moderately firm around the base. Surface the whole with freshly-gathered Sphagnum Moss. The best time to afford fresh material or a greater space for root extension is when new leaves are seen pushing out from the centre of the plant. Water must be carefully afforded at all times. The principal thing to aim at is to keep the surface Moss in a living state all through the growing season. Do not allow water to lodge in the centre of the plant, or the leaves will decay.

TWO FINE ANGRÆCUMS.

WHENEVER seen in flower the Angræcums always create great interest, *A. eburneum* and *A. sesquipedale* being among the finest of the genus. Their large, ivory-white flowers, with the long spur from the base of the labellum, are very attractive, while the plants even when not in bloom are noble subjects for any warm-house. Both are native of Madagascar.

A. EBURNEUM first flowered in the Royal Horticultural Society's Gardens at Chiswick in November, 1831. For some years it was very rare, but now plants are often met with.

A. SESQUIPEDALE was found by the French botanist Du Petit Thouars some 120 years ago, but it was introduced by the Rev. W. Ellis in 1855. He brought home three living plants, and one flowered in the spring of 1857. A hybrid has been raised from the two species quoted, and is known as *A. Veitchi*.

Angræcums for the most part inhabit the hottest regions of the globe, and when grown in this country they must be placed in the warmest house where the atmosphere is kept humid when the plants are in active growth. Ordinary flower-pots are the best receptacles, and these must be filled to one-half of their depth with drainage, over which is laid a thin layer of Moss to secure a free outlet for water. Repotting should be done when the plants have become leggy and new roots are pushing out from the stem. The rooting medium should consist of Osmunda-fibre and Sphagnum Moss in equal parts with a sprinkling of crushed crocks or charcoal added. The last layer should be live heads of Sphagnum Moss, which will grow and keep the roots in a moist and cool condition. Shade will be needed whenever the sun is hot, and the plants must be afforded copious supplies of water throughout the spring and summer months. At other times the soil should be just moist or the leaves will shrivel and fall off. There are upwards of fifty species of Angræcums. The large kinds may be grown in pots and arranged on the stage, but the smaller species may be placed in Teak-wood baskets and suspended from the rafters. *A. citratum* is one of the best. B.

PLATYCLINIS.

At one time these were known as *Dendrochilum*, and in some gardens are still grown as such. The individual flowers are neither large nor showy, but the drooping scapes are always admired. There are few species, and all are native of the Philippines. In

P. COBBIANA the flowers are straw-yellow with an orange-yellow lip, and the scapes are produced in late autumn.

P. FILIFORMIS flowered for the first time in 1841 in Mr. Bateman's collection at Knypersley, Cheshire. The racemes contain upwards of sixty blooms, which are canary-yellow and slightly fragrant.

P. GLUMACEA is probably the best of the genus, the graceful drooping racemes appearing in April. The flowers are yellowish-white and possess a pleasing fragrance somewhat resembling new-mown hay.

CULTURE.—Flowering at different periods of the year, the repotting is carried out at intervals to suit each individual plant. As a general rule they should be given warm-house treatment, although I have seen some fine examples grown among the Cattleyas, especially *P. glumacea*, which will thrive where the temperature is cooler. The repotting is carried out a week or two after the flowers fall, employing a mixture of Osmunda fibre or good peat, Sphagnum Moss, and partly-decayed Oak leaves. The pots

should be filled to one-third of their depth with drainage, over which is laid a portion of Sphagnum to secure a free outlet for water. Throughout the growing period the plants should be placed in a light position, but where they are shaded from the direct rays of the sun, and afforded copious supplies of water. As the pseudo-bulbs mature the supply is gradually diminished, but sufficient must be given to keep the compost just moist and prevent the pseudo-bulbs shrivelling. This is important, because if they are allowed to suffer from dryness to any great extent the growth is not so vigorous the following season.

SADOX.

FERNs.

HARDY FERNS IN THE GREENHOUSE.

In many towns, and often in congested suburban districts, a glass structure (according to the builder a conservatory) is attached to the dwelling-house. Very frequently from its position it gets no sunshine, and in some cases little direct light. Any attempt to grow the general run of greenhouse plants therein will only end in failure. What is more, there is rarely any arrangement for keeping out the frost, so that tender plants will, in the event of cold weather, soon perish. In this case by far the most satisfactory plants to grow are hardy Ferns, most of which will succeed under such conditions, and very effective specimens may be grown. It is sometimes said that they are of but little interest during the winter, but such is by no means the case, as the various forms of the common Polypody, *Scelopendrium vulgare*, and *Polystichum angulare* are very effective when several of the others are dormant. In making a

SELECTION one should, if possible, go to a nursery and choose those that suit his taste. These Ferns vary so much that forms which one person would prefer might be by another passed over. Personally I do not like the extremely congested forms of *Scelopendrium*, or the very de-auperated varieties of other kinds, but by some they are selected on account of their distinct character. The culture of the more accommodating of these hardy Ferns is very simple, thriving as practically all of them do in a mixture of loam, leaf-mould or peat, and sand. Nice specimens may be grown in pots from 5 inches to 7 inches in diameter. Occasionally an extra vigorous specimen may need a larger pot, but in a general way the sizes above mentioned will be ample. Effective drainage is very necessary, for the plants will require plenty of water, especially during the growing season, but at the same time stagnant moisture is very injurious.

REPORTING, if needed, may be done in spring, just before growth recommences. It need not, however, be limited to that period, as in the first half of the summer, when the roots are very active, they soon take possession of the new soil. When in growth the roots should, in potting, be disturbed as little as possible. In potting, some plants need the soil to be pressed down more firmly than others. In the case of Ferns this should be moderately done, as if too firm or too loose it is not favourable to the welfare of the plants. It is also very essential to leave sufficient space for watering. Many of the hardy Ferns can be increased by division, and when it is intended to do this the operation should be carried out in early spring, before the young fronds are pushed forth. If there is a portion of bare stem, as happens in some kinds, it should, in potting after

division, be buried somewhat deeper than it was before.

CULTURE.—In structures such as that above indicated the greater portion of the light comes, as a rule, from one direction, hence the plants should be turned round frequently in order to ensure symmetrically-shaped specimens. In summer a gentle dewing with the syringe once or twice a day will be beneficial. While most of these Ferns are better in pots, the Polypody and its varieties, being of a shallow-rooting nature, may be grown in deep pans, and under these conditions the rhizomes have more room for their development. They may also be grown in suspended baskets, but in this case care must be taken that they do not at any time suffer from want of water. In the case of deciduous kinds the roots must be kept moist during the winter, but, of course, less water will be required than in the growing season. The question of stimulants for Ferns has of late cropped up. I have never experienced any harm from the judicious use of liquid manure, soot-water, or any of the well-known stimulants.—K. R. W.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

NOTES AND REPLIES.

Bulbs in the wall garden.—Some of the early bulbs which have been tried in my wall garden are now becoming established. One particular example which gave me great pleasure was some bulbs of *Chionodoxa Lucilæ* between the stones of a low retaining wall with a considerable "batter." The stones are red sandstone and are now nicely covered with green Moss. The bright glaucous green of the leaves of the Glory of the Snow, and the blue, white-eyed flowers, made a beautiful picture. On the same wall there are Snowdrops and Snowflakes, with, by and bye, some Dog's Tooth Violets. In another wall there are some Snowdrops, but this is not a retaining one, but simply a double one, with earth between, built for a screen and to accommodate rock plants. Here double Snowdrops are especially pretty.—S. ARNOTT.

Fritillaria Meleagris alba.—The Snakes' heads have always had a charm for me, and I have a lot of the white variety planted in different parts of my rock garden. They came into bloom about the end of April and look very graceful growing up through a clump of *Saxifraga bathoniensis*. The plant is found in meadows, and I think it likes the coolness which it finds when growing through a mossy *Saxifraga*. The flowers are not of a pure white, there being a greenish tinge about them, which, however, in no way detracts from their charm. They do not seem at all particular as to soil so long as they are not in too dry a position.—N. L.

Saxifraga Bakeri.—This delightful *Saxifraga* is just starting to bloom (May 17th). Belonging to the Mossy section, it is from 4 inches to 6 inches in height, and the flowers when they open are of the brightest crimson. It is rather similar to *Bathoniensis*, but dwarfer, and, if anything, of more compact habit. Another good point about it is its long flowering season. It usually lasts from May to the end of June. After the flowers have been open a short time the colour is a very pleasing dark-rosey shade.—E. T. ELLIS, *Wetwood, Ecclesall, Sheffield*.

Nemesias in the rock garden.—Some most delightful effects are produced if the seed is sown now in a sunny spot in the rock garden. Last year, when on my holiday, I saw the varieties Orange Prince and Blue Gem (9 inches to 12 inches high) naturalised in this way, and I never saw anything nicer. The seed should be sown thinly and covered only very lightly. All that remains to be done is to keep the plants well watered, thinning out as needed later on.—E. T. ELLIS, *Wetwood, Ecclesall, Sheffield*.

TREES AND SHRUBS.

IVY.

THE illustration shows the effective use of Ivy, where it is not likely to damage neighbouring subjects. Over the open space on the right-hand side of the picture is a strongly-built stone archway connecting different parts of the garden. The arch supports a public footpath, which is hidden from view by an iron fence fixed on the top and clothed with Ivy. The banks on both sides, and for some distance around, are composed of a stony clay soil quite unfit for choicer things, and on these are growing large Hazels and groups of Blackthorn trees 30 feet or more in height, many of which are very picturesque gar-

a year, when it should be cut hard back. April is the best month for this, as the young fresh leaves develop rapidly after this date. There are few more conspicuous features in the winter landscape than a large Ivy-clad tree. It is generally assumed that Ivy is detrimental to the welfare of trees, but on this point authorities differ. I have often noticed that a tree well clothed with Ivy often looks very sickly during periods of drought, the cause of which is undoubtedly the Ivy sapping the moisture. E. M.

TRANSPLANTING WITH BALLS OF SOIL.

LOOKING through some old gardening periodicals recently we came upon an article on transplanting trees with balls

been disturbed, especially of smaller ones, and it is the general experience of planters that the preservation of even a few roots, in this way undisturbed, is almost a guarantee of success. There is the soil covering compactly the roots, no drying out by exposure has occurred, and a solidity of soil surrounding the roots is assured, such as no pounding or ramming of it under other methods of transplanting could bring about. Planting with a ball is almost the equivalent of planting from a pot, not quite the same when some roots are lost in digging to form the ball, but with a certain number of roots safely ensconced in the body of soil taken in the ball the tree is simply root-pruned, and not greatly checked.

Another advantage of the ball to a large

Ivy allowed to grow naturally over an arch.

landed with this finest of all evergreen climbers. The banks and the surrounding ground are one thick rich green carpet. The arch and fence above it are no longer visible except for the passage way, thus emphasising in the best way possible its great value and charm. Very different is the case with Ivy on houses, stables, sheds, etc., for here it is often dangerous, climbing in at the windows if not attended to every few days, choking spoutings, and if left, eventually covering the whole roof.

For clothing ruins, tree-stumps, bowers, fences, and bare dividing walls it is excellent. Ivy, in my opinion, is far more beautiful than hard, stiff, cut lines of Box and Yew. Moreover, it does not offer the same protection to vermin as the latter, and only requires trimming off once

of soil, in which the writer of the article was opposed to the ball when trees were large, and, in fact, contended it was unnecessary at any time. His objections were that in the case of large trees it was the custom to dig a small circle around the tree, chopping off all roots extending beyond it, whereas if no attention was given to the preservation of a ball the roots could be followed to their extremities. Then, with careful pounding of the soil around the roots in planting, it was just as good as a ball would be, while much greater lengths of roots had been secured at the same time.

While it may be accepted without question that the more root the better the prospect of success, yet there is much in favour of a ball of soil. There is then a certain number of roots which have never

tree is its keeping the tree in a firm position when it is planted. Many a large tree, moved without a ball, has its chance of living destroyed by its swaying about in gales, the roots giving to the call of the branches as gales sweep them about, for pound the soil as one will, a large tree will so sway about in gales that the roots must move to some extent, as the leaning trunk often indicates. Even when planting without a ball there is a better way of encasing the roots in solid soil than by pounding, or ramming the soil. A good pouring in of water will do it. Nothing solidifies soil better than watering, and then there is the additional benefit of the moisture to the roots. Give first choice to a ball of soil in transplanting, the next one to a soaking of water, in order to aid success.—*The Florists' Exchange.*

VEGETABLES.

CELERY FOR LATE USE.

I AM afraid at times we coddle Celery too much and sow too early when the produce is required as late as possible. I have had it in use from October, sown early in March in a frame or on a bed of warm leaves. I prefer the leaves to manure, which frequently heats violently and the seedlings are much weakened. Sown thinly in rich soil, with a few inches of rotten manure underneath for the roots, the seedlings can be lifted with good balls, and may be planted out in their permanent quarters in the middle of May. I do not like pricking off. To avoid this there must be no crowding in the seed-bed and no delay in planting out. It is surprising how quickly dwarf, compact seedlings, if well hardened off, take to the soil, and there is much less trouble afterwards in watering. Seedlings planted out in the middle of May for autumn use have quite five months to perfect their growth. Early kinds may with advantage be employed, and as regards size much depends upon the demand and tastes of the household. I now come to the late or April-sown Celery. For this I would select a warm corner fully exposed to the south, and sow as early in April as possible. There should be good rooting material under the top soil, which must be fine and light. Many persons advise a raised bed, a gain, no doubt, at the start, but not so, later, as the moisture drains away and the soil dries so quickly. Thin sowing is imperative as it must be remembered the seedlings in their early stages must have room to develop, as they have to be lifted with a ball and taken direct to their permanent quarters. Dryness at the root or delay in planting out will in a great measure account for hollow stems and poor quality. It may be asked would this mode of culture answer in the north? To a certain degree it would, but much depends upon the grower. In the north it is an easy matter when sowing the seed to cover with frames or mats and assist germination. With cold frames available it would be an easy matter to sow thinly in these and get a splendid plant. My chief objection is employing strong heat, making a weak plant, that takes weeks to recover, if it ever does. Frequently one sees quite large plants, which, when planted out, topple over, being so weak.

Celery grown as advised will not be so large as one often reads of, but sturdy, good, and well flavoured. I fail to see the value of Celery of great size. For keeping it is not advised, and when of compact growth it is hardier. Moulding up must not be done too early or too much soil added at one time, this causing decay of the centres and considerable loss. A great deal depends upon the soil it is grown in. In heavy soils I found it a good plan not to make deep trenches but wider ones, and plant four rows to six rows of plants, the soil previous to planting having had a liberal addition of burnt garden refuse placed in the trench and then well incorporated with the top soil. I had good heads up to April; not large, certainly, but solid and with little waste. In this way I always grow the Celery for cooking. For cooking, a dwarf form was preferred. Colour was of no importance, as after the New Year a pink or red Celery loses much of its colour. As a rule, Red Celeries are much hardier and keep better in severe seasons than the white varieties. W. F.

GARDEN FOOD.

CELERY IN COOKERY.

A RECENT reference to the good form of Celeriac in GARDENING ILLUSTRATED made me think of its importance generally. One of the heaviest labours in the garden, especially in heavy soil, is earthing-up Celery, and it is not by any means certain that it is always for the good of Celery in wet years. One of the improvements of late has been the growing of the Turnip-rooted Celery, which is as good for the cook as the other Celery, and does not want one-sixth of the trouble. Those kinds of Celery, also, which are grown on the Continent as self-blanching should be tried more than they are. They will not give the crisp Celery that we want for our tables, but they will do for the cook for flavouring, and there seems to be a chance of improving some of them. Cooks, as well as gardeners, are apt to neglect the Celeriac even when well done. That is a great mistake, as, on the Continent, it has various good uses. W.

ORANGE SALAD.

IN your issue of March 4th you refer to several forms of Orange salad, but omit one American favourite—Orange and Lettuce. Line the salad-bowl with Lettuce leaves, then heap it with the white-heart leaves mixed with sliced Orange, from which skin and white pith have been removed. Toss a little French dressing over it, or pass the dressing separately if desired. A dusting of paprika is an attractive garnish. This is delicious with cold meats or with roast duck. Grape-fruit is used with Lettuce in the same way, but I prefer the Orange, as the Grape-fruit with French dressing is sometimes too acid.

American housekeepers compound many wonderful salads of fruit, Nuts, and cooked vegetables, some of which, like Banana, laid upon Lettuce leaves, masked in mayonnaise, and then covered with chopped Peanuts or Pecans, sound rather like a dyspeptic's nightmare, but this really tastes as good as it looks, and it makes a very pretty salad. "Ambrosia" is an American dessert that includes Oranges. It consists of shredded Pineapple and shredded Orange arranged in alternate layers, each layer well dusted with powdered sugar and covered with freshly-grated Coconut. Arrange in a glass serving-dish, dusting Coconut over it and chill before serving. This is easily prepared, and served with sponge-cake is very nice for a warm evening, when heavier desserts are undesirable.

EMILY TAPLIN ROYLE.

Maywood, New Jersey.

NOTES AND REPLIES.

Late-keeping Apples.—I see in your issue of GARDENING ILLUSTRATED of 15th April many kinds of late-keeping Apples recommended. I have not had the pleasure of trying them, but no doubt one of the best late kinds, and a very strong grower, is Alfriston, which cannot be gathered till about November, and keeps with me till end of May. The tree I have is very large, and a very good regular bearer. Of course, soil has much to do with it. Mine is a sandy loam. D'Arcy Apple is very good, but does not keep so long, and bears only every other year. I am very anxious we should improve upon having the best kinds in our orchards now we have so much competition. Blenheim Orange is another splendid Apple, but it takes so long coming into bearing unless

grafted on another free-bearing sort. For an early, prolific, regular cropper you cannot beat Golden Spire. I always have to thin the trees very many times during the fruiting season.—C. P., Blandford, Dorset.

Natural seasonings best.—We find the following in the *Guardian* and agree with it. The most mistaken cook is the one who abandons herbs for spices, and these not all wholesome. The reason of the delicate flavour of some French and Italian dishes is the great use there of herbs from a garden plot. It would be a great gain to health if all the pepper and other seasonings used by the town cook were put into the nearest sewer and the stock not renewed.

In view of the fact that vegetables—like everything else—are expensive at the present time, and that you cannot make savoury dishes without the help of *bouquets*, it is wise to use all ground available for growing those things that will help to supply the kitchen, and thus save some expenditure. Those with plenty of space at their disposal may well "take a little strip for the herbiary under the eye of the mistress, and thus recover to our cups and salads some of the comparatively neglected herbs whose place is nowhere to be found now save in the pages of old herbalists."

NATURAL SEASONINGS BEST.—Success in cookery depends to a large extent on the proper use of seasonings and flavourings, and greater attention than is usually thought necessary should be paid to this point, which no cookery-book can teach. Whenever possible, natural seasonings should be chosen in preference to made-up condiments, and fresh or dried herbs are all simple, and do not cost much to grow.

PLEASANT HERBS.—Marjoram, which should find a place in every *bouquet garni*, and in forcemeats of different kinds, is a perennial plant of easy culture. Basil, of pleasant smell and taste, should be sown in a hotbed in April and transplanted in May into light but good soil, putting the plants about 9 inches apart. The flower-stems should be cut when ready and dried for winter use. Chervil, used either dried or fresh, is highly appreciated.

SUBSTITUTE FOR ONIONS.—Chives are best used fresh as flavouring for soups and salads.

Asparagus.—This is one of our best vegetables, but it is often ill treated by the cook, who has often to deal with a poor, ill-grown "grass." Over-cooking and boiling the heads off are the common fault of cooks, but much of the stuff grown is so poor that the cook cannot serve it as it ought to be and is commonly served in other countries. The way of serving it cold, crisp, and dry, as in France, should be followed here. The mistake of all is the close planting, which has gone on for many generations in our country, and can never be done satisfactorily except in very good soils, and even then the "grass" is poor and small. Asparagus is a vigorous plant and wants room to grow in. The right way is the single drills, the plants not closer than 1 yard apart, and the lines not close either. It takes long to get this into the heads of gardeners. Growing Asparagus on heavy clay soil is a hard job in any case, and the difficulty is increased by the stupid way of packing the plants close together. On the other hand, where the soil suits Asparagus, it should be more frequently grown for the market.

OUTDOOR PLANTS.

SPRING FLOWERS IN THE GRASS.

I HEAR much grumbling lately because of loss of flowers, owing to the gardeners being taken away for the war. The loss is quite unnecessary, for if the people who have charge of public parks made good use of the land no weather could spoil the spring display. At a time when places like Hampton Court Gardens look desolate, because of the lack of bedding-out plants, my lawn and woods have never looked better. The cold and wet weather has failed to hurt any of the beautiful hardy things left to grow year after year. Here is a little example of planting, a quarter of a century ago, Daffodils of various sorts and other hardy flowers. They have had no attention since. By a little stream which tumbles into the lake close by I have some hardy bulbs, as also

whether the plants died suddenly or the reverse, or whether the dead ones are all together or occur at more or less irregular intervals. The failure is, however, of so exceptional a nature that we advise you to institute the closest inquiries on the spot. If you are able to obtain any information from so doing, we should be pleased to hear from you in due course.

HARDY FLOWER NOTES.

THE DITTANY OF CRETE (*Origanum Dictamnus*).—"W." (page 227) is quite right. This requires a very warm, light soil, and, I should say, can only be grown with any prospect of indefinite endurance in the warmest districts of this country. I saw it once in a flourishing condition in a Surrey garden, but the soil was more sand than loam, which never becomes water-logged, and in a hot, dry time gets so warm that many things become semi-roasted unless well watered or artificially shaded. Has "W." ever tried it in a mixture of broken brick, mortar rubble, and

the rockwork if I were Mr. Philips, and have all ready for transplanting in September, as he says he can do. This is the best month in the year for planting alpine, as the ground contains much warmth, and we are pretty well sure to get nice rains during the month, which firm the soil, and the plants get firm hold of the ground before winter comes, and are, therefore, less liable to frost-heaving.

WHITE SPANISH SQUILL.—On a piece of ground which is very poor and not favourable for hardy plants there are twenty clumps of this Squill carrying some 200 fine spikes of bloom, and the effect is decidedly good. Those who need an abundance of flowers for cutting should bear this in mind. It can be bought cheaply by the hundred, and will thrive in any poor ground. A little bit of culture, however, improves the quality of the flower-spikes. This may consist of a winter top-dressing of leaf-mould or garden refuse.

Flowers naturalised for a quarter of a century. Moat Cottage, Gravetye Manor.

the Siberian Iris and Pontic Kingcup. Snakes' heads grow in a moist part of the lawn. Globe flowers flourish near. Most of these plants are often not quite so good in the garden as in the Grass, in which they are let alone. Snowdrops, Crocuses, and the Blue Wood Anemone help the picture in their season.

W.

Gentian dying (J. H.).—Why the plants of Gentian have died off in the wholesale manner described is by no means clear, and, further, it is most unusual. Once established, as yours appear to have been, the plants invariably go on for years, usually covering an increasing area and flowering well. In the circumstances we can only suggest a fungoid attack or some local cause of which we have no information. Had you sent us plants when the failing was first observed, we might have been able to throw some light on the matter. It is possible that some virulent poison, as weed-killer, or salt, or even wood-ash fresh from the garden rubbish-fire has been applied to or quite near the plants. This last is very rich in potash and other quickly-soluble salts, and if liberally applied might prove dangerous. You say nothing of the nature of the decay,

sand in a very sun-baked position on a mound or very elevated part of the rockery? It is the inability of the roots to withstand the combined influence of wet and cold that makes its life precarious in English gardens. In any case some protection to the crowns, such as a cone of leaf-mould or ashes, would probably be necessary against extreme cold. In former years cottagers grew this in their windows in this district and called it the Hop-plant, and sometimes the Hop Marjoram, but the Zonal Pelargonium banished it as it did some other things then much grown.

MOVING ROCK PLANTS.—I cannot agree with the advice given on page 233 to move these at the present time, just when they are beginning to do themselves some good. I do not say it cannot be successfully managed, but it is risky, and, should a period of hot, dry weather set in, involves a lot of attention. I should get on with

I see no difference in the purity of this Scilla and the Roman Hyacinth.

PRIMULA DENTICULATA AND P. D. CASHMIRIANA.—Mr. Jenkins hits the nail on the head when he speaks of these as fit companions for our wild species. The shade, the shelter, and the sub-moist atmosphere which prevail in the copse and woodland, even in very hot weather, mean life and happiness to them, whereas the arid atmosphere and exposure in an open garden spell decrepitude and even death. These exotic Primroses are children of the woods, and are lost children when away from their protective and invigorating influence. I have seen the Cashmerian Primrose growing under these conditions evidently as luxuriantly as in its native wilds, and seeding and perpetuating itself as freely as does the Primrose in our woods and copse land. In the open it is generally short-lived, dying off from dry

rot at the crown, but I have grown it with fair success in the Grass.

SAXIFRAGA CRISTATA.—A pretty neat-habited little encrusted species this, but none too vigorous. It is liable to be lifted out of the ground by frost-heaving, and, therefore, should be well looked to. It is a delicate-rooted kind, and the soil for it should contain an extra amount of sand, with plenty of sandstone or something similar. J. CORNHILL.

"IN A COLLEGE GARDEN."

I HAVE been so interested in your criticism of "In a College Garden" that I feel impelled to write to you. Your criticism seems to me so absolutely just. At present there seems a mania with women to want to do what is a physical impossibility—to plough, spread manure, dig, shoot, and drill to defend the country! A more miserable sight than Lady Wolseley's lady gardeners bowed over a spade I cannot imagine. It is true that the peasant women abroad work in the fields, but the fact that they not only do tasks within a woman's strength, but beyond, is surely shown in their look of premature age. Then, also, I am so glad that you insist on the value of long apprenticeship to the work. I am afraid that the war will produce a large crop of thoroughly inefficient lady gardeners and workers on the land, accepted just now as stop-gaps, but all to be got rid of as soon as there is again male labour in the market. I think that gardening within limits is a delightful pursuit and interest for women; that milking, dairy work, light work in the fields are excellent for them, and might supplement men's work, though machinery is taking the place of women, for instance, in the hay field. But why cannot women take up the work of commercial travellers (I know of one who is doing it very successfully), shop work, clerk's work, and return to the domestic interests—kitchen and house? Why should Lady Wolseley make out that all gardeners (male) are stupid and dishonest?

ROSAMOND A. CHRISTIE.

P.S.—I must add a postscript to tell you that I have a delightful outdoor gardener—a rectory-trained man, but your "English Flower Garden" is his gardening Bible, and your paper his delight. His plants thrive amazingly because he takes endless pains, and gets his soil so free and tilled "that one could eat it." We are horribly short handed (I have to undertake the weeding), but despite all, we have carried out a new bit of stone ditching and re-made a badly or non-drained border. Despite the winter, he has brought through alive, and practically unhurt, *Lisianthras*, *Plumbago capensis*, *Abutilons*, and *Tacsonia van Volxemi* on the terrace walls. The really good working gardener is a delightful person, and his ambition for the garden—"the best in the place and for ladies and gentlemen to come from a distance to see"—is most pleasing.

—Many persons interested in horticulture will be glad of the remarks made in reviewing "In a College Garden," by Viscountess Wolseley. Gardening is an excellent occupation for many girls and young women strong enough to endure the hard and dirty work it entails, but if "the woman gardener, like all head gardeners" (*sic*), expects to be "paid in proportion to the amount of brain-fag, deception, and other disagreeables that by honesty and intelligent supervision she rescues her employer from being the victim of," she will often be disappointed. There is, surely, no reason why a girl trained for a year or two at a horticultural

college should be paid as much as a head gardener with years of experience. Viscountess Wolseley must know that in most of the so-called learned professions young men usually spend from three years to six years before earning anything at all, and frequently after a University education. The lady gardener is not the only one of her sex who sometimes imagines she can learn in three months what a man would take three years to learn. The business world to-day is crowded with young women and girls who have no notion of their limitations. Some advertisements of business training colleges actually appeal to "ambitious women and girls." Women are doing such splendid work, especially in nursing, teaching, and in making munitions, that it is a pity that others are too often quite unable to see their own strict limitations. This applies particularly to those who have quite recently turned their hand to agriculture or gardening.—H. S. T.

THE GLORIES OF THE SNOW.

MR. MARKHAM'S excellent notes on the Glories of the Snow should increase the favour shown to them, as they are now cheap. A well-known bulb grower, long departed, told me that he had paid £1 1s. each for three bulbs he selected from a batch of imported *C. Lucillæ* at the time of its introduction to commerce, and packets of seeds were offered by an enterprising midland firm at 2s. 6d. each for the benefit of those who could not afford to buy bulbs. Now the Glory of the Snow is cheap enough for almost everyone who can afford to buy bulbs. I may perhaps be allowed to supplement Mr. Markham's notes.

CHIONODOXA LUCILLÆ.—The bulbs introduced to commerce under this name are not Boissier's original *C. Lucillæ*, but represent Maw's finds when searching for Boissier's *C. Lucillæ*. Boissier's variety, which is now in commerce, is of a much brighter colour, the shade of blue being altogether warmer and more approaching that of *C. Tmolusi*. I grow both Maw's and Boissier's *C. Lucillæ*, and the latter is the superior form, handsome as Maw's plant is in every way. There are now several white varieties of this, and I have some raised here from white seedlings sent me by the late Max Leichtlin. They vary a good deal in size and purity, but all are very pretty. The pink varieties, of which I have selected some good seedlings, are also extremely beautiful.

C. TMOLUSI.—This is the latest of the type of *C. Lucillæ*, and comes from a different district. It is of a brilliant purple-blue with a bold white eye. A really good Glory of the Snow.

C. GIGANTEA.—A white variety of this is a great beauty.

C. SARDENSIS.—When this was sent out it was recommended because the white eye was practically suppressed, but there are really two forms of *C. sardensis*, the one just alluded to and that spoken of by Mr. Markham with the conspicuous white eye. The latter is not so plentiful—at least so far as my information goes.

C. NANA.—This is the rarest and least desirable of the Glories of the Snow, but it is a pretty and interesting little plant. It has small flowers of almost violet-blue with little of the white eye. It comes from Crete and is not, I think, offered at all at present.

CHIONOSCILLAS.—These hybrids between the Glory of the Snow and the *Scilla* are interesting. They have been found in Nature and also occur in gardens. I have a few of these and they are all beautiful. One very pretty one is soft

pink, passing off to almost white. It was raised by the late Mr. James Allen and named by him The Queen.

S. ARNOTT.

ANNUALS.

WHERE the best annuals, such as annual Sunflowers, Cosmos, Malope, Godetia, Gaillardia, Cornflowers, Gypsophila, and Mignonette are required in quantity for cutting, it is always advisable, especially if the provision for artificial watering is neither adequate nor convenient, to sow respectively on sunny and shady borders. Given a rainy summer, the former will be decidedly the better, but in a very dry season a border having a northerly site anywhere round from due east to west is certainly preferable; indeed, in very exposed, sunny situations it is doubtful if three parts of the seed would come unless the drills were soaked previous to sowing. The above-named annuals are so useful, coming in, as they do, at a time when the glory of the earlier herbaceous flowers, as *Pyrethrums*, *Irises*, *Pæonies*, and *Pinks* is nearly gone, that, common flowers as they are, a little extra labour bestowed in the way of culture and after attention is well repaid. Not the least valuable characteristic is their long duration when cut, much more enduring than one would suppose from the thin and, in some cases, almost semi-transparent petals. Very beautiful bouquets and nosegays can be made from these annuals, the delicate panicles of the annual *Gypsophila* playing an important part in the arrangement. The combined wealth and duration of flower furnished are quite enough to make one understand that these annuals will pay for good treatment, or rather that the nature of the display will largely depend on this. The borders for their reception should be dug in winter as deeply as possible, working in plenty of manure. If the ground is rather on the light side it is a good plan to give a slight treading. No mention of annuals to supply cut flowers would be complete that did not include Sweet Peas.

NOTES AND REPLIES.

Tufted Pansies.—Where these are required to give a late summer display the flowers should be picked off as fast as they form, so that the plants may be kept growing vigorously. If one does not care to sacrifice the flowers entirely, they ought not at least to be left on to form seed pods, as so many of the *Violas* do freely. Straggling plants, kept one year should have their shoots pegged down and be well mulched, but such plants never give such good results as young stock, so far as late flowering goes.

The inflated Bladder-pod (*Vesicaria utriculata*).—This is again very attractive on a little eminence in the rock garden, showing to much better advantage there than in the border. The yellow flowers are succeeded by small bladder-like seed-pods. *V. utriculata* seems to prefer a dry soil and a sunny position, and will last for years. Old plants are, however, apt to become scraggy and should be replaced after a few years by young ones.—Ess.

Aubrietia Peter Barr.—It is not possible to appraise justly the merits of the large number of deep purple *Aubrietias* now in commerce. It is, perhaps, sufficient to say that this is worthy of consideration even by those who favour Dr. Mules, Prichard's A 1, and others of the newer deep-purple *Aubrietias*.—S. ARNOTT.

Bicolor Trumpet Daffodil Florence Pearson.—This has been one of the most beautiful of all the bicolors here this season. The flowers, which are of large size, are yet very refined, and the soft colouring is most acceptable. Florence Pearson is one of the good doers and has been greatly admired.—S. Dumfries.

Alyssum saxatile Tom Thumb.—It is unfortunate that this dwarf variety of the Golden Madwort is such a shy bloomer. It is only a few inches high, is of more rigid habit than the others, and never covers itself with the little golden flowers in the fashion of the larger varieties of this Rock Madwort.—S. ARNOTT.

Border Carnations.—If not already done, these should now be neatly staked, and a sprinkling of soot and wood ashes hoed into the borders.

THE CHELSEA SHOW.

MAY 23RD-25TH.

THE May exhibition of the Royal Horticultural Society, which opened on May 23rd and continued the two following days, must be considered a success. A great exhibition in every way, one whose influence is felt even in the remotest corners of horticulture, this annual show—decidedly the most popular held under the auspices of the Society, long since exceeding the bounds of a mere flower festival—is now regarded as of national import. Early in the year the question as to holding this and other shows was seriously considered by the Council, and the decision arrived at to continue them, though on a modified scale, has been amply justified. In these circumstances the show this year is smaller than any of its predecessors in the Royal Hospital grounds at Chelsea, albeit it is a great show, and in view of the increasing tax that such exhibitions must be to horticulturists, big enough for all purposes; for a show can be too big to be enjoyed or appreciated by the public at large. Thus in great measure the show is a representative one; the missing link the fascinating rock gardens, which, since the days of the International Show, have constituted such a feature, and done so much to further the interests of hardy plant gardening generally. For the rest, the marquees teemed with the choicest products of greenhouse and garden. Finer exhibits of greenhouse annuals—*Calceolarias*, *Cinerarias*, and the like—than those from Reading, Raynes Park, and Stourbridge have rarely been staged. Roses from the ablest growers were in great beauty and variety everywhere. Carnations we have seen on a larger scale, though not of finer quality, a remark which applies with equal force to *Begonias*.

Orchids were seen to perfection on a modified scale, and naturally not a few of the choicest. Hardy plants and alpine were in great numbers—enough, indeed, and to spare—many of the choicest things being presented on an imposing scale. An item of importance not to be overlooked in this great—while greatly modified—exhibition is the entire absence of second and third-class material. There is, indeed, no room for such, just as to-day there is little need for it in the garden. Many good novelties received recognition. Following we give some of the chief features of the show, which we hope to continue in a subsequent issue.

HARDY PLANTS.

For many years now we have gone to the spring, or May, exhibition of the Royal Horticultural Society in the hope of seeing something new in hardy plants, and we have never gone in vain. We say this looking back to early Temple show days, when a solitary spike of *Eremurus* brought, if we remember aright, by the late Mr. Gumbleton from Ireland, created something in the nature of a sensation, and from which time to the present hardy plants have continued to grow and increase in popular esteem till now they find favour with all. Nor is the end yet. Year by year brings its quota of novelties. And still they come, increased either numerically or of enhanced importance, affording new opportunities and opening up greater possibilities to the hardy plant gardener than ever before. Novelties from foreign lands have ever fascinated the plant lover, and while the value of these remains to be tested, the insatiable zest of the cultivator urges him on to further trials in the hope of getting something both new and worthy. During recent

years much has come to our gardens from China and Thibet, and to-day the specialist is revelling in the newest additions from both countries. Happily the majority of these newcomers is not only quite hardy; they are singularly well suited to British lowland gardens, hence their increased beauty and ever-increasing interest. Moreover, hardy plants were never so well known and understood as they are to-day, and with the knowledge travellers and collectors impart of their native haunts the cultivator is assisted to give most of them what they require almost at the start.

Of a show of such magnitude as that at Chelsea no review, however apparently complete, could possibly do it justice, hence some details of its more important phases must suffice. To this end we single out the comprehensive collections of

Messrs. Wallace and Co., Colchester, rich as they are in home-raised hybrid Irises as well as the newer introductions from China and elsewhere. Of the Irises, *Shiren*, *Dorak*, and *Dilkash*, hybrids of the Bearded and Cushion forms, defy description. Suffice to say the weird markings of the latter, wedded to the perennial vigour of the former, have given us something new in the garden for which there is ever room. Mrs. Alan Gray is a rosy-flowered hybrid from Queen of May and *Ciengalti*, while *Purple King*, *Kharput*, and *pallida* in force afford endless beauty and variety. The rarely-seen *Iris bracteata*, a Californian species with yellow flowers, gained, as it deserved, an Award of Merit. Such Lilies as *odorum*, *Krameri*, *Batemanie*, and others were strongly represented, though even greater interest, perhaps, centred in the new Chinese *Primulas*—*helodoxa* (yellow), *nutans* (lavender), *conica*, *membranifolia*, and others—some of which we hope to refer to in fuller detail in a subsequent issue.

Messrs. Barr and Sons, Covent Garden, W.C., presented a great bank of hardy flowers, one aglow with the brilliance and splendour of Oriental Poppy and *Paonia*, while rich in the infinite beauty and grace of the Irises. Of these latter, *Walhala*, *Dorothea* (pale blue), and *Kharput* were some of the more conspicuous. *Paonia Ceres*, a single-flowered *officinalis* akin to *P. lobata*, was very beautiful in its salmon-cupped form. It gained an Award of Merit.

Messrs. George Bunyard and Co., Maidstone, showed a great wealth of the bearded Irises as a frontal group to a brilliant background of *Rhododendrons*, the lovely pale-pink *Mrs. Sterling* flanking either end superbly. *Pentstemon Scouleri* we have not seen so fine before, or so liberally displayed. *Allium Ostrowskianum* (rosy-red) was distinct. The Dutch bulbous Irises were very good.

Mr. Amos Perry, Enfield, brought a rich collection of hardy Ferns, a great bank of tree *Paonies*, of which *Elizabeth*, *Imperatrice Josephine*, *Mme. de Vatry*, and *Athlete* were some of the more fascinating, a gorgeous lot of oriental *Poppies*, among which the brilliant crimson black-blotched *King George*, jagged of petal and of great size, commanded attention. It gained an Award of Merit. Perry's White Poppy is remarkable by way of contrast. A new golden-yellow *Arnica* is called *sachalinensis*, and a hybrid *Dianthus* of Mule Pink tendency and single flowers was labelled *Fosteri*. It is dwarf, exceedingly brilliant in colour, and good. Irises were shown in great profusion, our only regret being, owing to the limitations of space, that we cannot give them in detail.

Mr. J. C. Allgrove, Middle Green, Langley, Slough, sent a capital lot of new

hardy plants, a reflex, as it were, of that greater wealth of novelties to which, for so many years, his predecessors (Messrs. Veitch) devoted so much attention. Cramped rather for space by reason of the unsuitable character of narrow tabling, there yet was still to be seen a considerable variety of meritorious subjects. Of these, one of the more important was *Primula tangutica sulphurea*, which, larger in all its parts than the original species, also promises well as a garden plant. *Primula Mrs. Berkeley* was particularly good and striking, while such modern species as *Forresti*, *conspersa* (Award of Merit), *geranioides* (pendent red flowers), *capitata*, *sibirica sinensis*, and *sikkimensis* all claimed attention. A new single *Paonia* with finely-cut leafage was labelled *P. Veitchi*. It is distinct from all.

Messrs. Blackmore and Langdon, Bath, sent a particularly good lot of *Delphiniums*, which, though forced to some extent, were still very finely presented. Rev. E. Lascelles, King Bladud (a deep blue sport from the last), *Lavanda* (a novelty in heliotrope or mauve), and Mrs. A. J. Watson (mauve and blue) were some of outstanding merit. Messrs. Godfrey and Son, Exmouth, staged a particularly good lot of *Papaver orientale bracteatum* varieties, the best being *Sandringham* (reddish-claret) and *Princess Mary* (rosy-mauve).

Messrs. John Waterer, Sons, and Crisp, Bagshot and Twyford, had a big circular group in which the showier *Lupins* were a chief feature, the rose and pink shades of *L. polyphyllus*, the blue and white *Foxi*, and the beautiful rose and white *Moerheimi* being among the best. All were shown liberally and well. *Verbascum Mrs. D. A. Lascelles* and *Iris Mrs. Alan Gray* (of rosy-lilac hue) were very fine.

Messrs. Reamsbottom showed *Anemones* very finely from Ireland, and thus grown, in blue, violet, purple, rose, and other shades, there is nothing finer for the spring and early summer flower garden.

Messrs. T. S. Ware, Feltham, had the too rarely seen *Paonia officinalis rosea plena* in great perfection. It is one of the most desirable, something to be grown by everybody. The most distinct plant in a group from Messrs. Artindale and Son, Sheffield, was the purple-feathered *Meadow Rue*, *Thalictrum aquilegifolium purpureum*.

ROCK GARDENS AND ALPINES.

There were no rock gardens in the open at Chelsea this year, and the fact, doubtless, to some extent accounted for the congestion in the vicinity of the alpine exhibits. This was in no sense surprising, remembering the interest now taken in this section of hardy plants and in view of the frequency of the exhibits, the store of material—choice and rare—and the cultural excellence which characterised so many of the plants shown. In this connection we give the exhibit from

Mr. Clarence Elliott, Stevenage, Herts, pride of place if only for the lavish display of *Pentstemon Davidsoni*. Imagine a 2 inches high miniature alpine sub-shrub, with roundish glaucous leaves, having brilliant carmine nearly 2 inches long tubular flowers jutting out in twos or threes in all directions on 3 inches long horizontally-disposed stems, and readers will have some idea of one of the choicest alpine in the show. Many other plants, *Pentstemon Roezli*, *Aquilegia glandulosa*, *Silene acaulis fl.-pl.*, *Iris cristata*, *Geum Bois-sierii* (pale orange), were in the group, and, cleverly disposed, afforded an idea of the rightful use of such things.

Mr. Reginald Prichard, West Moors, Wimborne, also brought many good things.

In this collection was seen the greatest variety of alpine novelties the exhibition contained. The hybrid *Dianthus Lansdalli* (Sweet William x Chinese Pink) was most brilliant. *Sedum humifusum* is a golden-yellow $\frac{1}{2}$ inch high Stonecrop of rare merit and beauty. It gained an Award of Merit. *Phlox Douglasi*, *Hypericum Kotschyianum* (yellow), *Dianthus alpinus albus*, *D. Prichard's Pink*, *Edraianthus serpyllifolius lilacinus*, *E. Pumilio*, and *Silene Hookeri* were other notable things.

Messrs. Tucker and Sons, Oxford, arranged many of the choicest alpine plants associated with rockwork. Here we remarked the rare and beautiful *Anemone narcissiflora*, *A. alpina*, *Campanula Cenisia*, *C. Allioni*, the dwarf-growing, rosy-flowered *Iberis jucunda*, *Silene alpestris grandiflora plena*, the too-rarely-seen *Anthyllis montana* and *Linum capitatum*. Mr. G. Reuthe, Keston, Kent, had an extensive collection of good and choice things, among them *Oxalis adenophylla*, *Ramondia serbica*, *Primula capitata erosa* (a newcomer of great beauty), and *Erinacea pungens* (sky-blue flowers on a 6 inches high bush).

Messrs. Whitelegg and Page, Chislehurst, went in strongly for free-growing subjects in conjunction with selected weathered Yorkshire limestone. *Ethionema Warley Rose* was a big feature. *Ourisia coccinea* (scarlet tubular flowers) was very fine, and the new *Saxifraga calabrica*, with handsome white plumes, was very good. Messrs. Piper, Bayswater and Barnes, showed many beautiful and showy alpine, including *Phlox canadensis* *Violet Queen*, *Viola gracilis*, *Lithospermum*, and *Ethionema Warley Rose*. Quite rich in novelties was the group from

Messrs. Bees, Limited, Liverpool. Of such, *Roscoea Humeana*, *Malvastrum coccineum*, *Weldenia candicans*, *Primula Smithiana* (yellow), *P. Reidi* (white), *Androsace coccinea* (*Bulleyana*) (Award of Merit) (approximating to *Kalanchoe flammea* in colour), *Clematis chrysocoma* (pinkish-white, in the way of *montana*), and *Rohleria Forresti* (yellow tubular flowers and *Ramondia*-like habit) being some of the more important. *Primula conspersa* (Award of Merit), *P. Menziesiana* (blue), *P. tibetica* (a rosy miniature of *P. farinosa* but 2 inches high), and the rich red *P. Rusbyi* were others of note.

Mr. Maurice Prichard, Christchurch, Hants, had some excellent things, including the white-plumed *Smilacina racemosa*, a shade-loving subject of great charm, *Androsace Watkinsi* (rich red), *Veronica bombycina* (silvery of leaf and pale-blue flowers), *Iris gracilipes* (quite dark form), and some pretty colonies of alpine Primks.

Mr. James Douglas, Edenside, Great Bookham, staged an excellent lot of Auriculas for so late a date, the green-edged *Wm. Smith* (the finest in the group), *Othello* (a very dark variety), and *Dean Hole* being some of the more conspicuous. Choice alpine and allied subjects were particularly well shown by

Messrs. John Waterer, Sons, and Crisp, Bagshot and Twyford. Here, among many, were remarked a pretty colony of the miniature-growing *Viola Lady Crisp*, hardy *Cypripediums* in variety, the blue-flowered alpine *Phlox Douglasi*, *Dianthus neglectus* (*Wargrave* variety) (very showy and good) *Oxalis adenophylla*, *Lewisia Cotyledon*, *L. Howelli*, *L. columbiana*, and *oppositifolia*.

Bakers', Wolverhampton, had *Dianthus Freynei* (one of the miniatures of the race), a mass of bloom, *Edraianthus serpyllifolius major* (rich imperial purple),

Pentstemon glaber roseus (very beautiful), *Haberlea Ferdinandi Coburgi*, *Bletia hyacinthina* and *alba*, and *Cytisus Dallimorei* in capital form.

FRUIT AND VEGETABLES.

These have usually formed a conspicuous feature at the shows held in previous years, both at the Temple and at Chelsea, but this season, owing to circumstances with which the public are, unfortunately, now only too familiar, the usual contributions were not forthcoming, with the result that only two collections of fruit—one of orchard-house trees in pots and one of vegetables—were staged. The premier exhibit of fruit was contributed by

The Hon. J. Ward (C.V.O.), Chiltern, Hungerford (gardener, Mr. C. Beckett). It consisted of an extensive and comprehensive collection of fruit made up of some two dozen Melons of well-known varieties, such as *Ringleader*, *Emerald Gem*, *Sutton's Scarlet*, *King George*, *Superlative*, and a seedling unnamed; numerous bunches of *Black Hamburg* and one of *Foster's Seedling Grapes*; several dishes of *White Marseilles* and *Brown Turkey Figs*, *Hale's Early Peach*, *Cardinal Nectarine*, and very fine *Red* and *White Currants*. The Melons were particularly good examples and exhibited high culture. Several of the bunches of Grapes were, when the earliness of the season at which the show is held is taken into consideration, excellent samples, though rather deficient in colour. The other collection of fruit alluded to was staged by the

Messrs. Laxton Bros., Bedford. This consisted entirely of Strawberries in a gathered state, the central position being occupied by plants in pots well laden with fruit of their promising new introduction named *Laxtonian*. There were also two baskets of the same variety which, with the foregoing, fully demonstrated its value as a good forcing and free-cropping variety. The fruits in appearance and size are similar to that grand old variety *Sir J. Paxton*, as it used to be some five-and-twenty years ago. Other varieties staged were *King George*, which has now an established reputation as a forcing variety, maturing its fruits some ten days in advance of the well-known *Royal Sovereign*, *The Earl*, and *The Duke*, which has evidently much of the blood of *President* and other fine old sorts in it. This gained a silver Knightian medal. The collection of fruit trees in pots, already mentioned, and to which a silver-gilt Knightian medal was awarded, was arranged by

Messrs. T. Rivers and Sons, of Sawbridgeworth, in a tasteful manner, Ferns and foliage plants being used to fill up the intervening spaces between the trees. The centre of the group contained well-laden trees of *Early Rivers Plum*. In front of them, on both faces of the group, which was oblong in form, were freely fruited specimens of *Early Rivers*, *Elton* and *Knight's Black Cherries*, *Duke of York Peach*, and *Cardinal Nectarine*. On the margin of the group were arranged several well-fruited examples of *Oranges* in variety.

Messrs. Sutton, of Reading, had the only exhibit of vegetables to be seen. The disposal of the various dishes, needless to say, was carried out in the usual artistic manner for which the firm is noted, and the general quality of the exhibits throughout was excellent. Some well-cropped plants in pots of *Wax-pod Butter Beans*, and of *Plentiful* and *Masterpiece French Beans*, served to illustrate the value of all three when utilised for this method of culture. Peas in a gathered

state were splendidly represented by the firm's well-known introductions, such as *Early Giant*, *Duchess of York*, *Hundred-fold*, *Improved Pilot*, and others. Of *Potatoes* *Balmoral Castle*, *Stirling Castle*, *Warwick Castle*, *Edinburgh Castle*, and *Dunbarton Castle*, some excellent dishes were noted. Other features comprised very fine *Globe Artichokes*, excellent *Turnips* and *Carrots*, *Winter Beauty Tomatoes*, *King George* and *Pride of the Market Cucumbers*, *Table Dainty* and *White Bush Vegetable Marrows*, *Mushrooms*, *Cos* and *Cabbage Lettuces*, *Radishes*, *Cauliflower* *Magnum Bonum*, *Late Queen Broccoli*, and *Flower of Spring Cabbage*.

Owing to want of space we have been compelled to hold over notes as to *Roses*, *greenhouse plants*, etc., which we hope to deal with in our next issue. A complete list of the certificated plants and medals will be found in our advertisement columns.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM MAY 18TH.—*Quinces*, *Brooms*, *Jew's Mallow*, *Piptanthus nepalensis*, *Laburnums*, *Bush* and climbing *Honeysuckles* (in variety), *Pearl Bush*, *Sweet Bay*, *Lilacs* (in great variety), *Viburnums*, *Spiræas* (in variety), *Hardy Heath*s (in several forms), *Magnolias* (in variety), *Coronilla glauca*, *C. Emerus*, *Perrettias*, *Gorse*, *Vaccinium pennsylvanicum*, *V. Vitis Idæa* and its major variety, *Cydonias* (in many colours), *Cornus florida rubra*, *Weigelas* (in variety), *Sand Myrtle* (*Leio-phyllum burifolium*), *Judas-tree* (*Cercis Siliquastrum*), *Dophnes* (in variety), *Andromedas*, the *Alpine Clematis*, the *Mountain Clematis* (in various colours), *Ribes speciosum*, *Mexican Orange* (*Choisya ternata*), *Native*, *American*, and *Japanese Cherries* (in variety), *Azaleas* (in great variety), *Rhododendrons* (in great variety), *Rocky Mountain Bramble* (*Rubus deliciosus*), *Grevillea rosmarinifolia*, *Staphylea colchica*, *Mountain Ash*, *Broad-leaved Spindle-tree*, *Pyrus Malus* (in great variety), *Euonymus alatus*, *Camellias*, *Amelanchier canadensis*, *Pyrus arbutifolia*, *Lonicera pileata*, *Wistarias*, *Corylopsis* (various), *Potato-tree* (*Solanum crispum* and its *Glasnevin* variety), *Chinese Chestnut* (*Xanthoceras sorbifolia*), *Deutzias*, *Akebias*, *Kalmia glauca*, *Periwinkles*, *Partridge Berry* (*Gaultheria Shallon*), *Anemone Rose* (*R. sinica Anemone*), *Siberian Crabs*, *Chestnuts*, *Berberis* (in great variety), *Laurustinus* (various), *pink* and *white May*, *Cistus salvifolius*, *Pæonies*, *Barrenwort* (*Epi-medium*) (in variety), *Scilla campanulata* and its *pink* form, *Honesty* (white, rose, and purple), *Coronilla minima*, *Cornus canadensis*, *Star of Bethlehem* (*Ornithogalum*) (in variety), *Anchusos* (in variety), *Solomon's Seal*, *Saxifragas* (*Mossy* and *encrusted* forms), *Megaxsas*, *Forget-me-nots*, *Primulas* (in variety), *Erinus* (white, rose, and purple), *Cheiranthus linifolius*, *Sun Roses* (*Helianthemum*) (in variety), *Gentiana verna*, *G. acaulis*, *Helichrysum trinerve*, *Ranunculus speciosus fl.-pl.*, *Alpine Phlox* (in great variety), *Wahlenbergia serpyllifolia*, *Houstonia cærulea*, *Alpine Achilleas*, *Lithospermums* (in variety), *Oxalis enneaphyllo*, *O. tropæoloides*, *Cistus alyssoides verus*, *Candytuft*, *Saponaria ocymoides*, *Alpine Veronicas* (in variety), *Monroe's Mallow*, *Pentstemon Scouleri*, *Ethionema cordifolium*, *A. persicum*, *Gazania splendens*, *Gypsophila prostrata alba*, *Linums*, *Dryas octopetala*, *Columbines*, *Kenilworth Ivy* (white and purple), *Linaria aquiritiloba*, *Tulips* (in variety), *Camassias*, *Wood Lilies* (*Trillium*) (pink and white), *Lily of the Valley*, *Bleeding Heart* (*Dicentra spectabilis*), *Wallflowers* (various colours), *Lupinus nothaensis*, *Armeria Lauchiana rubra*, *Viola cornuta* (in variety), *Antennaria tomentosa rubra*, *Dianthus deltoides ruber*, *Iris germanica* (in variety), *Potentillas*, *Grape Hyacinths*, *Meconopsis sinuata latifolia*, *Lady's Slipper* (*Cypripedium Calceolus*), *Tufted Pansies* (in great variety), *Kingcups* (*Caltha*) (in variety), *Water Hawthorn*, *Fumitory*, *Asperula*, *London Pride*, *Geranium lancastriense*, *Windflowers* (in variety), *Hyacinthus amethystinus*, *Mazus rugosus*, *Geums* (in variety), *Iceland Poppies*, *Lychnis diurna*, *Foam-flower* (*Tiarella cordifolia*), *Summer Snowflake*, *Rheum palmotum*, *Globe-flowers* (*Trollius*) (in variety), *Asphodelus luteus*, *Stylophorum diphyllum*.

WORK OF THE WEEK.—A further planting of *Sweet Violets* has been made on a cool border, the varieties used being *Princess of Wales* and *Italia*. In wet weather soil has been sifted, this coming in useful for surfacing beds where seedlings and various other small plants from cuttings are to be put out and grown on for a time. The alpine borders have been overhauled and the soil broken up among the plants wherever possible. Such things as *Nierembergia rivularis* and similar subjects which form a carpet in themselves have had fine soil shaken in among them. Gaps—where

the plants have been taken away for other purposes, such as edgings to beds, etc.—have been filled up with the following plants: Lithospermums, Pentstemon Scouleri (rooted cuttings and seedlings), Pentstemon isophyllus varus, Shamrock Pea, Monroe's Mallow, Pratia Arenaria, Felicia abyssinica, Veronica Bidwilli, V. Lyalli, Linaria alpina, Erinus (bright rose coloured), Erigonum umbellatum, a few plants of *Ethionema cordifolium*, and *Cistus alyssoides* varus. A double line of Dahlias in several varieties has also been planted out from boxes. The removal of dead flowers from Narcissi and other bulbs growing in the borders requires frequent attention. A few years ago the Blue Thistle (*Mulgedium alpinum*) was planted among some Azaleas here. This has now become a perfect pest, rambling about under the surface, and coming up everywhere, despite all our efforts to get rid of it. I hope this will be a warning to others—who may not know it—to keep it outside the garden. In the wild garden or in any out-of-the-way corner it will hold its own with tall Grasses or any other native plants—indeed, this is the place where it gives of its best, the blue flowers being very pretty. A flight of steps with Hairbells between the stones and a deep wall on either side, containing the little Sandwort (*Arenaria balearica*), Mossy Saxifrage, etc., has been cleaned over, and the plants freshened up. The same applies to rows of the Native Gromwell (*Lithospermum purpureo-ceruleum*), which furnishes the ledges on either side. A large bed has been planted with *Fuchsia corymbiflora* and its white variety. As these were in large pots, the soil was well rammed round the balls of roots to prevent undue dryness before they got established. Another bed has been planted with a number of mixed kinds of *Fuchsias*. E. M.

Sussex.

SOUTHERN COUNTIES.

Bouvardias.—Bushes of the variety *Humboldtii grandiflora*, the young growths of which have been stopped, must now be hardened off, as they will be planted out in their summer quarters the first week in June. They will occupy a narrow border in front of a Peach-house, an admirable position for them, and where they flower in great profusion during August and September. A little fresh loam and spent Mushroom-dung applied to the border every other season serve the requirements of the roots and encourage free growth.

Specimen plants.—Examples in large pots and tubs of *Fuchsias*, *Zonal* and *Ivy-leaved Pelargoniums*, etc., must now be gradually hardened so that they can be placed in position. This hardening requires care, as the foliage, being so tender, quickly burns if exposed too suddenly to the rays of the sun. To get over the difficulty many of the plants are placed, when first taken out, on the north side of a wall. Here the foliage soon becomes firm and hard, and in the course of a week or ten days the leaves can stand the sun with impunity. Other plants which cannot be so treated are shaded with muslin used for the exclusion of wasps and flies from vineries.

Flower beds.—With the exception of some few filled with *Panicles*, which are yet making a fine display, the beds must now be dismantled and made ready for their summer occupants. Plants of a perennial nature, such as *Aubrietias*, *Arabis*, *Yellow Alyssum*, and so on, should be lifted, divided, and planted in lines in a part of the garden contiguous to the water supply, as until new roots are emitted, and the plants become established, they must be kept well watered. The double white *Arabis* is a showy subject for spring bedding, and the several varieties of *Aubrietias*, whose flowers range in colour from a rose shade to deep purple, are always admired. Bulbs such as early-flowering or Dutch *Tulips* and *Hyacinths* should be lifted and laid in shallow trenches in a border to ripen off. These bulbs, when cleaned and stored away, are useful in autumn for planting in the wild garden and for similar purposes, but are of no further use for making a display in the flower garden. May-flowering *Tulips*, on the contrary, prove of great service for many seasons in succession if taken care of.

Annuals.—On the whole, these have come up well, and much thinning needs to be done. Failing to do this in a proper manner is generally the cause of these showy subjects lasting but a short time in bloom. When left too thick they become drawn and starve one another. Whatever the various subjects grown may be, sufficient space should be allowed the plants in each instance that they may develop properly, when the return in the shape of flowers will be tenfold that obtained from perhaps half-a-dozen plants occupying the same space. Some few annuale transplants successfully, but, as a rule, they do not, and are not worth the trouble. The best way is to resow or to fill the vacancy with some other appropriate subject when a partial or total failure occurs, half-hardy annuals, such as *Dianthus*, *Phlox Drummondii*, etc., coming in handy for this purpose.

Maincrop Carrots.—These, owing to the depredations of the Carrot-fly, are a partial failure, and a fresh sowing has had to be made on another plot which was surface-dressed beforehand with soot and lime mixed together. The bare places in the drills which occur in the first-named instance will be planted with *Cauliflowers*.

Parsnips.—Good results have accrued from the second sowing, and thinning will take place in a few days.

Turnips.—The plants from the last sowing are now ready for thinning. The raising of Turnips has so far been done under great disadvantages this season. In the first place, small birds are so very numerous that unless good nets are used, and made thoroughly secure round the outside of the plots, they get in and demolish the plants as fast as they appear above ground. Then, as soon as the surface of the soil is dry, hots of the flea-beetle appear, devouring the leaves of the plants and quickly ruining them. A daily dusting of the plants with soot and lime while dry weather lasts renders the leaves unpalatable and gives the plants a chance to grow away from them. Manure-water sprinkled over them also deters the insects and stimulates growth. Fortunately, recent heavy rains have rid the plants for a time, at any rate, of this pest. Advantage will now be taken of the soil being in a moist condition to get a good large breadth sown. As the seed germinates quickly it is hoped the plants will be able to make good headway before the surface again becomes parched and the jumpers reappear. A little guano sown in the drills does good, as it greatly accelerates the growth.

Early Celery.—This is now ready for planting. The variety is *Superb White* which is found to be the most suitable for early supply. The soil over-lying the manure in the trench is in a nice friable condition, and there will be no difficulty in obtaining a sufficiency of fine "crumb" with which to fill in round the balls when planting is done. The plants are in just the right condition for setting out, neither too large nor too small, and as each can be lifted with a good ball they should, after being watered, hardly feel the change. For some little time the roots will find all the stimulus they require beneath them in the trench. The plants are set out four in a row in the width of the trench, each row being 1 foot apart.

Spinach.—Warmer weather and an abundant rainfall have so stimulated the growth of the early sowings that were it not for its being in daily demand a wastage through its running to seed would surely occur. As it is cleared off the ground is planted with *Lettuces*. Successional rows of true *Spinach* have again been sown, and a good breadth of *Spinach Beet* got in at the same time as this does not, like the former, bolt almost as soon as it is ready for use. New Zealand *Spinach*, which was sown in pots will be got out directly all danger of frost is past.

Scarlet Runners.—A good look out for slugs, which, as a result of so much wet weather, are very numerous and destructive, must be kept until the plants have made sufficient growth to be out of harm's way. A mixture of soot and lime strewn on either side of the rows in and down the centre of the drills in the trenches proves as good a deterrent as anything. By this it will be gathered the seed is sown two rows in a trench, and where staking is done the stakes cross each other near to the tips. This method is found to answer best, as the stakes, when laced together at the top in the manner stated and with their butts let well into the ground, offer greater resistance to westerly gales in autumn than they would if grown in single rows.

French Beans.—These have germinated well, and the plants are, so far, growing freely. A further and larger sowing will now be made, the varieties chosen being *Magnum Boum* and *Selected Canadian Wonder*. The drills for the former will stand 2 feet apart, and for the latter—on account of its being of such a robust habit—2½ feet apart.

Vegetable Marrows.—The maincrop plants will now be planted out on disused hotbeds or any suitable place that can be found for them. No protection for these is required, as frost of any account is seldom experienced after this date. A few plants set out in frames occupied by *Violets* will yield an early supply of fruits.

Tomatoes.—As the position where these are grown outdoors is sheltered on three sides and open to the south on the other, they will now be planted in raised narrow borders, strips of turf being placed above the level on their outer edges to prevent water running to waste. Stakes, each about 5 feet in length, are used to train the plants to, and these are tied at the tips to a wall. This is done to avoid driving a number of nails into the face of the wall. Should the weather turn cold, mats will be hung in front of the plants at night.

A. W.

MIDLAND COUNTIES.

The latest *Vines* are now in flower, and as soon as the berries are set the growths must be regulated, the laterals stopped, and shoots tied down to the wires. Much care is necessary in tying down, especially with such varieties as *Black Alicante* and *Appley Towers*, for at this stage the shoots are easily broken off. They should be trained in the right direction and gradually pulled down at intervals of a few days, until ultimately they can be tied in their proper positions on the trellis. Remove all surplus bunches as soon as it can be seen which are needed for furnishing the crop. Late *Vines* must not be overcropped, this being one of the chief causes of shanking and a hindrance to perfect ripening. The thinning of the berries must not be delayed when

once they are large enough. Free-setting kinds swell very quickly at this time of year, and the berries are, therefore, liable to get damaged through overcrowding. Late *Grapes* should be more severely thinned than early ones, for the berries need more room to mature without nudly pressing each other, a condition which is against their good keeping. At the same time they should not be over-thinned, especially at the top of the bunch.

Tomatoes in pots should be stopped when they have set five or six trusses of fruit, as they are not able to perfect such a heavy crop as plants growing in beds. Remove all side shoots, and where the foliage is obscuring the light and air from the fruit the leaves should be partly cut away, but not too severely, or this will cause a check to the swelling fruit. A batch of plants will be raised the first week in June for supplying fruit in late autumn. These plants, when established, will be placed in a sheltered position out-of-doors, and not be brought in again until autumn frosts are apparent. By that time each plant should have set several trusses of fruits, and these will carry on the supply till the end of the year.

Plant-houses.—Owing to shortage of labour and the importance of giving fruit and vegetables first place, the work in this department has had to be considerably reduced. In most cases only sufficient of the more important plants to retain stock is being grown. A small batch of *Begonia Gloire de Lorraine* will shortly be ready for potting into the flowering pots, which will be selected according to the strength of each plant. A suitable compost consists of good fibrous loam, peat, and leaf-mould, using these materials in equal quantities, adding a little spent Mushroom bed manure rubbed through a sieve, also a moderate quantity of crushed charcoal and silver sand. The soil should not be made too firm, as this variety of *Begonia* appears to like rather a loose rooting medium. After potting, the chief points to observe are care in watering, moderate heat, and atmospheric moisture.

Perpetual-flowering Carnations are all in their flowering pots, and are stood on a bed of ashes in cold frames. The only attention they now need is ample ventilation, careful watering, and an occasional look over for stopping the shoots. The extent to which stopping is carried depends on the variety. Some sorts should not be stopped after the first week in June, whilst others may be stopped up to the second week in July.

Bedding plants.—The hardier kinds having been got out, the planting of other less hardy subjects, if the weather is mild, will be pushed on. These include *Heliotropes*, *Begonias*, *Cannas*, and sub-tropical plants, which may safely occupy their outdoor positions by the end of the second week in June. Many standard plants, especially any which will be required again next season, succeed best when plunged in their pots. All plants should be made firm at the roots. Any that require staking should have stakes put to them at the time of planting. The plants should be given a good soaking of clear water on the same day as they are inserted, and afterwards frequent sprayings with a syringe or rose-can in hot weather will keep them fresh during the time they are becoming re-established.

Climbers grow rapidly at this season and require frequent attention in the way of regulating the young growths. Do not train climbers in a stiff or formal way, or their greatest charm is lost. The object in thinning out unnecessary shoots is to enable those left to develop in the highest degree, and, provided they are supported sufficiently to withstand winds, the more loosely they are allowed to grow the more natural will be their effect when in bloom.

Asparagus beds in full bearing will benefit by applications of weak liquid-manure, and during showery weather light dressings of guano. The beds must be kept free from weeds by hand-weeding. Young plantations should not be cut over too hard, and from this date it may be advisable to leave all new growth to mature if the Grass is at all weak.

Peas.—The last sowing of Peas will be made at the end of the first week in June, and these will furnish a supply of pods until frost sets in. *Autocrat* is the favourite variety here for this purpose, as it resists mildew. If the ground is dry at the time the trenches are made a good watering should be afforded on the night previous to sowing the Peas. This is an important detail, as the moisture hastens the germination of the seeds. The ground between the rows of mid-season and late Peas is mulched with rough manure so soon as the sticks are placed in position.

Cabbage and Cauliflower plants raised on a warm border from March sowings are now ready for planting, and, if possible, this will be done in showery weather. These will form a succession to those wintered in frames. Should dry weather set in after planting, copious waterings will be necessary. The earliest planted *Cauliflowers* will be greatly benefited by weak applications of liquid-manure.

Turnips are now sown every three weeks, *Manchester Market* and *Orange Jelly* being suitable varieties for June sowing.

Carrots.—A small sowing of stump-rooted varieties is made every three weeks, as young, tender roots are much appreciated.

Seakale.—Young plantations have advanced far enough to require attention. The plants are carefully examined, and the shoots reduced to one on each plant, taking care to leave the strongest. Little further attention will be necessary unless the season is very dry, when the beds require a liberal watering from time to time to encourage the growth, and as the season advances a sprinkling of nitrate of soda will assist the development of the crowns.

Vegetable Marrows.—All the later plants will now be placed in their permanent quarters, giving them some protection for a short time during cold nights. When these are grown on the flat, large holes should be taken out and a good barrowload of manure placed in each. All unsightly rubbish and leaf heaps may be planted with these.

F. GALLOP.

SCOTLAND.

Odd work.—A prolonged spell of wet weather having intervened, some time was devoted to what may be termed odd work. There is always at this time of the year an accumulation of dirty pots, and these have been thoroughly scrubbed and graded. Crocks of different sizes have been put in readiness for further use, and a quantity of rough siftings and of Moss has been gathered together for drainage purposes. The stock of labels was overhauled, and some little repairs necessary in the case of nets were attended to. Mats, which will not now be needed until the autumn, were dried, folded, and stored. A quantity of loam and leaf-mould was sifted and put in a convenient place. Only sufficient batches for present needs ought to go into the potting-shed now, for the soil soon becomes too dry to be usable.

Leaf-mould heap.—The leaves gathered during the autumn and winter of last year were during the week turned over. When leaf-heaps are turned it is sometimes found that those in the centre are quite dry; but this season the excessive rains of winter and spring have thoroughly moistened the heap. If time permits, the heap will receive a final turn over later on. A little soot and lime were sprinkled over the layers in order to destroy as much insect life as possible.

Manure-heap.—There is a great and increasing scarcity of yard and stable manure. During the week a day was devoted to carting Seaweed from the beach near by, and this was incorporated with the orthodox manure as the latter was turned over. The mixture makes a highly useful compost, and when the digging season once more comes round the heap cuts down well, and the mixture is short and easily dug in. The varieties of Seaweed available are *Fucus serrata* and *F. digitata*, both of considerable value, more especially when used in the way indicated.

Vermin.—Some traces of rats having been noticed, a campaign against them is being carried out. I think the use of traps is better than poisoning, for rats are very easily scared, and when a few have been trapped I notice that the survivors give the environs of the garden a wide berth for a time.

Among the vegetables.—Although the weather has been wet, yet some progress was made in the vegetable garden. More lines of Peas were staked, and a further sowing was made. The variety used on this occasion was again the Gladstone Pea, a sort which does very well. I think there must be different stocks of this fine Pea, for I notice that, while the shape and habit are identical, the pods from some sowings are larger and better filled than those from seeds procured from a different source. More Spinach (*Victoria Round*) was sown. It is necessary at present to coat the seeds of Spinach with red lead previous to sowing, for pheasants have developed quite a relish for them. At the same time a sowing of Spinach Beet was made. This is useful in the event of a warm summer, when round Spinach quickly goes to seed. A further sowing in August will suffice for this variety. A sowing of Broad Beans was made, the early-maturing types, of which *Agnadnice* may be taken as a type, being used. More Turnips were sown, and a final sowing of Carrots was made. The hoe was run through Potatoes on a warm border. These have come along rather quickly, and so far have escaped damage from frost. Presently the soil will be loosened and the Potatoes moulded up. Sited by the damp conditions, further supplies of Cauliflowers were got out, as were Hearting Kale and a few lines of Savoys for early use.

Asparagus is now fairly plentiful and of good quality. It is always as well to keep the beds cut closely while the season lasts. To prevent exhaustion of the soil, the hoe must be kept regularly at work, so that weeds may never be allowed to make headway. If it can be spared, a sprinkling of any good chemical fertiliser may be given with advantage when there are signs of rain.

Rhubarb.—Now that Rhubarb is being largely used, it will appreciate a mulch of any spare manure, this keeping the roots cool and prolonging the season. The present is a good time to select clumps for next season's forcing. Such pieces ought to be encouraged to make all possible growth and should not be picked from.

Gooseberries have set freely. A look round in the course of the week shows that they will be perhaps a trifle later than usual. They are

generally picked about Whitsuntide, and as that, too, is later this year, it is possible that green Gooseberries will, as usual, be available. So far, no signs of caterpillar are visible.

Morello Cherries on a north wall are now in fine bloom. They have not had very favourable weather, high winds and continued wet having been the rule lately. Nevertheless, no special anxiety is felt on behalf of these Cherries, which invariably give good returns. Both young trees and those of some age are equally promising.

Apples.—On walls and in well exposed situations the display of bloom is now general, and in less favoured parts in the open the flowering time will not be much longer delayed. A collection of young trees on a dwarfing stock is especially promising, while upon walls, Margil, Ribston Pippin, King of the Pippins, and Kerry Pippin appear to have set well.

Under glass.—The continued wet has caused a renewal of firing in greenhouses. Such re-potting as is needful is being attended to from time to time as becomes necessary. Among other things sown in the course of the week for autumn was a packet of Balsams. These have not been grown for a considerable number of years, but they are always interesting. *Celosia plmosa* and *C. p. aurea* were also sown. A good and bushy strain has been built up by annual selection for a number of years, and these showy plants are always admired. Stove heat will, while the present conditions last, be kept in the neighbourhood of 65 degs at night. In the case of greenhouses, only sufficient heat to expel damp is allowed, for at this time any excess of fire heat merely results in outbreaks of insect pests.

Melons in pits.—Lack of sun is hindering progress, although the plants continue to make a certain amount of growth. Pinching in the case of newly-pnt-out plants is done when three perfect leaves have been formed. This produces sufficient shoots to furnish the light. Very careful watering is necessary in the case of Melons in pits, as such plants are much more liable to be attacked by canker than those grown in the Melon-house proper. Let the water be luke-warm both for syringing and for watering. Similar cultural details are applicable to Cucumbers grown in pits.

W. MCGURROG.

Balmac Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Ostrowskia magna (*Inquirer*).—Any hardy plant nurseryman can procure this for you. Your best plan will be to raise it from seed, which will germinate freely in a cold-frame. The plant likes a deep, sandy loam, as the Carrot-like roots, when of full size, go down to a considerable depth, and require careful handling as they are very brittle. It is in many places a very disappointing plant.

Outdoor Cannas (*E. D. H.*).—Seeing your soil is heavy, we should advise you to take out a hole about 2 feet wide and 15 inches deep, into this placing some light soil composed of leaf-mould and sandy loam, with some rotten manure in which to plant the Cannas. After they have begun to grow you should mulch them well with rotten manure and give copious supplies of water if the weather is dry.

Hyacinths after flowering (*Twywell*).—You have done quite right in laying your Hyacinth bulbs after flowering into the soil, but they will be of but little use for blooming in pots if you purpose using them in this way. The best way is after the foliage has thoroughly ripened to clean them and store them until planting time comes round, planting them in any vacant spaces at the edges of the shrubbery. The flowers may come in useful for cutting.

Maggots in Rose-buds (*Rose*).—The maggots which eat your Rose-buds must be destroyed before they reach the flower-bud. This can only be done by constant hand-picking. The maggot is easily found, for wherever there is a leaf a portion of which is rolled up, there will the maggot be found. Pressure between the finger and thumb will kill it. Make a point of examining the leaves of your Roses every other day, and you will prevent any serious injury to the flower-buds.

Rose Fortune's Yellow (*Cornwall*).—You are quite right about the pruning of this Rose. It should be cut back hard after flowering. Cut the lateral growths well back to the main stems. Keep the plant well syringed and the house fairly warm. By so doing you should have a good growth by the autumn. Any small, weak shoots that appear should be thinned out during summer. After growth is completed in autumn the small lateral shoots that may appear late on the current season's growths should be cut back and weak points removed from all leading growths.

TREES AND SHRUBS.

Yew hedges bare at the bottom (*Twywell*).—You may cut down your Yew hedges fairly hard, but at the same time the pruning must not be of too drastic a nature. The best time to do this is as soon as the harsh winds of early spring are over. A very important matter in connection with old hedges, such as yours is, is that the ground in all probability

is in a very impoverished state and a stimulant would be of great service. It is also likely to be very dry. If so, you might, when pruning is done, loosen the surface of the ground and give a thorough soaking of water. Then give a top-dressing of loam and manure, watering frequently during the summer if the weather is dry. If the weather is dry after pruning, a syringing overhead on bright, warm days will be beneficial, as moisture applied in this way acts as a stimulant to the production of shoots from comparatively old wood.

VEGETABLES.

Beetles injuring Broad Beans (*A. V. Brickenden*).—Your Beans have been injured by a beetle known as *Sitona lineatus*. They are often very troublesome, especially where the soil is rough and affords a hiding-place for them in dull weather and at night. It is always well to firm the soil round the plants, so as to remove these hiding holes as far as possible. Spraying the plants with paraffin emulsion will keep the beetles away from the plants to a considerable extent, and this will be the best measure you can adopt.

MISCELLANEOUS.

Hedgehogs in gardens (*Wallflower*).—In its wild state the hedgehog feeds upon worms, slugs, snails, and insects, while in a state of confinement it will consume bread-and-milk, and if allowed the run of a garden will find the greater part of its living. It is very fond of cockroaches, and will soon clear a kitchen of these pests. You should provide some soft straw or hay for your hedgehog to take refuge in during the daytime. You will find it will feed more freely during the night. The hedgehog hibernates during the winter, and when kept in a state of captivity should be placed, in cold weather, where frost cannot reach it. A small box or hamper filled with soft hay is about the best receptacle. On its awakening from time to time from its winter's sleep a little food should be offered it.

SHORT REPLIES.

Mrs. A. Longfield.—No; the only way is to fork in some of one of the several soil fumigants now to be had.—*H. T. Shawcross*.—If you could loosen the surface of the walk, then the weed-killer could find its way through and not run to waste. 2, Yes. 3, We should feel inclined to let them grow naturally, and thus present a fine mass of colour. 4, If you want to see the beauty of the Scotch Fir, then by all means have the trees thinned out as you suggest.—*Doctor*.—Not black-spot; the trouble is probably due to the cold weather we had when the plants were starting into growth, and they will very likely grow out of it. If not, please send further specimens of leaves.—*Grape Vine*.—We fear you will have but little chance of success if you attempt to move such an old Vine. Far better destroy it and start with a fresh, young Vine, seeing to it that the border is carefully prepared for the same.—*E. Field*.—Now is the best time to do what you wish, but you will have to be very careful with the watering and shading until the plants are growing away freely.—*E. S. Bolton*.—We do not think there is any cause for alarm, as, with the warmer weather, the leaves will come all right. If not, please send further specimens, and we will do our best to help you.—*B. K. G.*—It is useless to advise without seeing the fly which you say is destroying your fruit. Please send a few specimens, and then we may be able to help you.—*A Regular Subscriber*.—For such a shaded position the only plants likely to do any good are hardy ferns. Flowering shrubs would be of no use, as owing to the wood not having a chance of ripening, there would be no bloom.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*H. G. Thompson*.—The Bird Cherry (*Prunus Padus*).—*Northam*.—*Mimulus luteus variegatus*, so far as may be judged from the specimens you send, and which have been very much knocked about.

Sale of plants, bulbs, books, etc., in aid of the British Red Cross Society.

The sale of plants, bulbs, horticultural books, paintings, prints, etc., which is being organised by the Royal Horticultural Society in aid of the funds of the British Red Cross Society and the Order of St. John, and is to be held in the Society's hall on Wednesday and Thursday, June 28th and 29th, promises to be a great success, and there is a steady flow of offers of objects for the sale. The catalogue will be issued on June 17th and will contain a list of all the gifts received under the names of those who have given them. All entries must be received by May 27th. The title cover will be designed by Mr. Byam Shaw, the *Punch* artist. It has been decided that the donors of Orchids and other objects of exceptional value may place a reserve price upon them should they wish to do so.—W. WILKS, Secretary.

TREES AND STORMS. *

In your issue of May 13 there is a note on the above by "W." I always read anything so initialled, and know that I am bold to make any criticism.

I live on the borders of Herefordshire and Worcestershire. This winter we have had three terrible gales, the last the worst, nothing ever being remembered like it by our oldest men. We appear to have been in the main track of the hurricane, which was apparently accompanied by whirlwinds, as whole belts of Fir-trees have had their tops screwed off 30 feet from the ground. I can point to very sheltered and screened valleys where great Oaks are torn up by the roots—not simply broken—to well-sheltered woods where Larches and Oaks are lying in a tangled heap like an upset box of matches. I have seen amongst them uprooted Holly and Yew trees. Of what use are wind-screens and sheltering-belts then? But it is "W.'s" last sentence that I take most exception to. He says, "It is sheer folly to plant the Field Elm or any other Elm anywhere almost." I ask what would the counties of Herefordshire and Worcestershire be without their glorious Elm-trees? I am aware many, very many, have suffered recently, but they are good timber, although windfalls. Yet there remain still standing and uninjured hundreds of thousands of magnificent specimens, beautiful, superbly beautiful, even though they are "dotted" and "spotted" in many a lovely golden buttercupped meadow or "rowed" in many a straggling hedgerow. If the gale had laid low the last I would plant again in feverish haste, for I would be a criminal to prevent a future generation seeing and worshipping one of the greatest beauties Nature produces. Even in winter they are more beautiful than the Yew, Holly, or Evergreen Oak, which are almost valueless for timber and too slow to rejoice our grandchildren.

ERNEST BALLARD.

Old Court, Colwall.

NOTES OF THE WEEK.

The Black Cottonwood (*Populus trichocarpa*).—In the interesting notes about the Poplars (May 20, p. 251) I find the finest of the kinds, *Populus trichocarpa*, which I have been planting lately, is omitted. It is a much finer tree than the Balsam Poplar and the others you name.—W.

Lysimachia Henryi flowered really well here last year from July to late in the autumn. This was protected with a sheet of glass, but is quite dead. It must be a very tender plant.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed*.

Lupinus nootkaensis.—There is often little difference between the Lupinus in gardens, and one may often see the old *L. polyphyllum* bearing several Latin names. This, from seed from British Columbia, is a graceful flower, soft-grained blue, rather dwarf, and fragrant. A good border plant.

Primula helodoxa.—My brother arrived yesterday with this, the most wonderful out-of-doors Primrose, growing in whorls of three. A glorious bright yellow. The flower-stems measure 39 inches. The two leaves, I see, are 17 inches. Messrs. Wallace, of Colchester, grow it, but at the Chelsea Show I hear they had it no taller than ordinary Maidenhair Fern.—C. R.

Cat's-foot (*Antennaria dioica*).—This now forms a very pretty little silvery edging with me, and covers the beds at this season with its rosy flowers. It is quite a pretty and distinct thing, and is a native of the poor heaths and sandy patches from Cornwall and Devon in the west and Suffolk in the east to Shetland. It is well to use native plants when they are good and useful, as they often are.—W.

A blue Everlasting Pea (*Lathyrus pubescens*).—This comes to us from Mrs. Rogers, at Burncoose. It is one of the things many cannot grow. It does fairly well on a wall among shrubs, and is well worth growing where climate allows. The flowers are charming in the house owing to their distinct colour and effect, and keep well. This, a native of Chili, may be worth growing indoors where it will not thrive out-of-doors.—

Fuchsias in Scotland.—There is already quite a noticeable quantity of bloom on a large plant upon a south wall. The date (May 14th) is rather earlier than usual. We have had no frosts heavy enough to do damage to Fuchsias in growth as yet. These and Deutzias, however, can never be considered out of danger till quite the end of May; indeed, in 1913 both were cut over by frost on the morning of the 2nd June.—W. McG., *Balmac, Kirkcudbright*.

Anchusas.—A pleasant change from the prevailing yellow of spring is now found in the Alkanets, just (May 16) coming into bloom. The variety known as Opal is, perhaps, the best, closely followed by

the Dropmore variety. The type, *A. italica*, if coarser, is, nevertheless, not at all had, and blooms very freely. All three, however, in a good border, are rather rampant (especially the last named), and might be used in a more fitting way in the wild garden or for naturalising in Grass.—KIRK.

Felicia abyssinica is a really good plant. In the autumn of 1914 a plant which appeared to be dead was given me. Soon after Christmas I pulled it up and forgot all about it till March, when, being evidently alive, it was replanted among large stones, deeply buried, on a slope facing west. A few flowers opened in September. At the end of November, being told it was liable to damp off during the winter, I covered it with a sheet of glass. This was removed at the end of March. The plant had increased by layering itself wherever it touched the soil, and is now quite 2 feet across, with any quantity of beautiful flowers.—E. C. BUXTON, *Coed Derw, Bettws-y-Coed*.

Bush Honeysuckle (*Diervilla præcox* var. *Floral*).—This is a lovely variety of the Japanese Bush Honeysuckle. It makes a shapely and graceful shrub, and at the present time (May 20th) is wreathed with bloom. The large flowers, freely produced, are of a deep rich pink with a carmine throat. Apart from their delightful colour the flowers are rendered exceedingly attractive by their protruding white stamens, which stand well out of the wide, open throat. We have it growing on a sunny and rather poor bank, interspersed with young plants of the white Broom, also in bloom. The combination is all that could be desired.—E. M.

The Blue Poppy (*Meconopsis sinuata*).—I am glad to read that this beautiful Poppy flourishes at Gravetye. I find that the easiest way to deal with it is to sow the seed (which it produces in abundance) in autumn in the place where it is required. Of course, it can be raised in boxes and the seedlings pricked out, but that is troublesome work, and seedlings which have never been disturbed are always best. Treated in this way we have it here in the chinks of a retaining wall facing north-west. There is another species now flowering in the Edinburgh Botanic Gardens whereof the lustrous sky-blue quite eclipses the delicate tint of *M. sinuata*. This is a variety of *M. simplicifolia*, a Poppy which, hitherto, has given me only rich purple flowers shot with blue.

The value of *M. simplicifolia* is greatly enhanced by the fact that it is a true perennial in a genus mostly biennial.—HERBERT MAXWELL, *Monreith*.

The Japanese Quinces.—These are flowering with great freedom this year, and are much admired. The clusters of bright flowers are welcome, and, though seldom seen grown in this way, they form lovely hedges when trained against trellises or on wires stretched between posts. *Pyrus (Cydonia) japonica* has given many varieties, among the prettiest I have being *nivalis*, with snow-white flowers, *cardinalis* (intense crimson), *rosea* (rose), and *princeps* (scarlet). They generally fruit well with me.—S. ARNOTT, *Dumfries*.

Lilium myriophyllum.—You have a note in your issue of June 3 on this Lily. It is a mistake to use this name any longer in connection with *Lilium regale*, or Wilson's Lily, which is the species to which your note refers. The true *L. myriophyllum*, so far as we know, is not in cultivation. We write not so much to correct the name as the cultural note you add to it. *L. regale* is not a Lily for "peaty or leafy soils," it is a lime-loving Lily, and does best in a fairly stiff loam with plenty of sun. In the right place it is a splendid hardy perennial, but in leafy and peaty soils it dies out.—R. WALLACE & Co.

Achillea ptarmica The Pearl and A. Perry's White.—I can see no difference in these two varieties here. I have difficulty in keeping these for more than one flowering season, and am inclined to think that they flower themselves to death. They seem quite hardy, as small new plants planted in autumn live and increase through the winter, and in summer flower profusely, but die off during the next winter. I see in Nicholson's "Dictionary of Gardening" it is advised to cut down the stems immediately the flowers commence to go over, and I intend trying this. Have any of your readers had a similar difficulty and found a remedy?—H. F. S., *Huddersfield*.

Iberis Little Gem.—Mr. Herbert Maxwell is right in saying Mr. Arnott is too kind to plants of no great beauty. I tried the above-named in a good place, and after fair trial threw it away. It did not show any of the beauty or vigour of other hardy evergreen Candytufts. It is the greatest mistake to take nursery catalogue descriptions seriously. Try the plant in a nursery bed before putting it in any place where a good effect is looked for. The surest way to lessen the value of hardy plants is the presence of poor plants, mere novelties, and plants of botanical interest. Botany and gardening are two different branches of knowledge, and myriads of plants of interest in botany are without value of any kind for the garden.—J. S.

The Rocky Mountain Bramble (*Rubus deliciosus*).—This is now in bloom. The large, single, pure white flowers, each 3 inches across, resemble single roses, and are profusely borne on long, arching sprays, which are delightful for cutting, every little side shoot carrying one single flower. In point of flower beauty this is the most effective of all the *Rubus* group. Although discovered as long ago as 1820, it is still rarely seen in gardens. Unlike most others of this genus, it is quite unarmed. In a Sussex garden I saw this shrub the other day trained to a wall, its slender branches spangled with flowers, which, at a short distance, looked like large single Roses. With me it is quite hardy in the open, where it makes a loose, though shapely, shrub from 4 feet to 5 feet

high and through. An occasional thinning out of the old branches is all the pruning it requires. It is one of our finest flowering shrubs, and a group at the height of its beauty is a feature in the garden at this season of the year.—E. MARKHAM.

The Falkland Island Wood Sorrel (*Oxalis enneaphylla*) in Scotland.—In a half-shaded but elevated part of the rock garden this is delightful this year. It likes a free root-run in light soil, loam, leaf-soil, or peat, and a little sand suiting it well. I believe it grows in full sun in its native country, but climatic conditions are different, and with us it appears to prefer at least partial shade. With me it is shaded from the morning sun, and is grown on a little flat in a small depression well up on the rock garden. The flowers, which are of a kind of satin white, are exquisite nestling on the surface of the foliage. It is perfectly hardy here.—S. ARNOTT, *Dumfries*.

Lupins.—This year the first spikes of *Lupinus polyphyllus* (blue and white) were in bloom on May 21st—about a week sooner than last year. In my exposed garden the first spikes are always small, but about June I get the best ones. The smaller plants in the borders last June carried eight to ten spikes, but one huge clump, three or four years old, had as many as fifty spikes out at once. I usually calculate that I have *Lupinus* in flower from now to mid-July by cutting the blooming spikes when they are at their best. Then I get no more for about three or four weeks, when a second crop begins, which lasts till the end of September. The spikes are, of course, smaller, but well worth having. No second crop is obtained if the spikes given in June are left on and seed saved.—E. T. ELLIS, *Wetwood, Ecclesall, Sheffield*.

Rhododendron Pink Pearl.—I notice in your issue of May 6th a note from Sir Herbert Maxwell with reference to the parentage of Pink Pearl. I should have thought that Sir Herbert Maxwell would have been perfectly well satisfied with the explanation that I gave to him through the medium of the *Field* newspaper, on the occasion to which he refers. I should like to repeat that the original seedling plant of *Rhododendron Pink Pearl* was raised in these nurseries, one of the parents being one of the *R. Manglesi* hybrids, which has been known for many years as George Hardy. It is of considerable interest to know that Messrs. Peter Lawson and Son used *Rhododendron Griffithianum* for the purpose of hybridising, but I should think it is quite evident from the number of hybrids emanating from many sources all over the country that a considerable number of other people have also used this species and its progeny for the same purpose. It would be interesting to know whether there is any original history in Scotland of *Rhododendron Alice*. Perhaps Sir Herbert Maxwell can give us some information with regard to this beautiful hybrid?—F. GOMER WATERER, *The Nurseries, Bagshot*.

The Mexican Orange-flower (*Choisya ternata*).—A good deal can be said in favour of this shrub, for it is an excellent evergreen, and bears fragrant white blossoms freely. Being a native of Mexico it is naturally tender and is unsuitable for the colder parts of the country, but it gives excellent results about London, while there are many places in the Midlands where it does well. At its best it attains a height of from 8 feet to 10 feet, with a similar diameter, but plants of half these dimensions are very effective. The flowers are borne in large heads near

the points of the shoots, the majority opening in May, although blooms can be found at various times during the summer. Cuttings of short shoots root quickly if inserted in sandy soil in a close frame in summer, and soon form good plants. Arranged in groups it is very effective, whilst it can be used for informal hedges and for planting in tubs for terrace or corridor decoration. In some gardens it is planted against walls and proves a good shrub for the purpose. Cut branches are useful for house decoration, particularly when good-sized shoots are selected, as the flowers have a pleasant orange-blossom-like perfume.—W. K.

FRUIT.

FRUIT-TREES IN BLOOM.

I READ with pleasure the very interesting article which appeared in your issue of May 27, page 257, as few objects are more beautiful during the spring and early summer months than our common cultivated fruit-trees. There is no reason why the fruit garden should not constitute a necessary portion of the "pleasure-grounds" of every country mansion. What can be more beautiful than the Apple, the Pear, the Plum, and the Cherry-trees when in full flower? In fact, they are exceedingly interesting objects at all seasons of the year. It rarely happens that they are placed in positions where their beauty can be appreciated and enjoyed. They are too frequently to be found in the quarters of the vegetable garden, where they are entirely out of place (unless it be in the form of espaliers or cordons); or they may possibly be found in a somewhat neglected and out-of-the-way locality known as "the orchard." But as an advance or an improvement upon this state of things, might not these useful and ornamental fruit-trees be cultivated with more pleasure and, at least, equal profit in the pleasure-grounds? Clumps or groups of varied forms and dimensions could be formed of pyramidal or otherwise trained Apple, Pear, Plum, and Cherry-trees, etc., which might be margined by low single cordons of their respective kinds, while single standard trees of various sorts might in suitable situations be allowed to assume their natural habit and dimensions, the whole area to be traversed by winding and comfortable walks, to afford every facility for the examination and enjoyment of the beauty of the various fruits in all stages of their development. Altogether, I am inclined to think that by adopting some system of grouping and by adhering to an arrangement which would associate the fruit garden with the pleasure-ground in such a manner as to constitute, as it were, a necessary and important portion of the same, and to some extent effect a combination of the useful with the ornamental, we could hardly fail to give additional interest to the surroundings of country mansions or smaller residences at all seasons of the year. A. G.

NOTES AND REPLIES.

The Pearmain Apples.—Perhaps Mr. Will Taylor can give us some information as to the origin of Carter's Pearmain, as it seems to be comparatively unknown and not to be found in fruit lists unless under a different name. I have always been interested in the Pearmain family, possibly because among the recollections of boyhood days are fine fruits gathered from old trees in a southern orchard. That old English Apple known as Winter Pearmain, Winter Quoining, Duck's Bill,

and Sussex Apple in different districts was one of the favourites, and at its best quite an excellent Apple. Another popular fruit was Autumn Pearmain, not so good in quality as the preceding. The two most popular Pearmain's of the present day are possibly Worcester and Adam's, but they have not much to recommend them, the former being notable for its earliness, whilst Adam's is a greatly over-rated fruit, not in the same class as Claygate, Mannington's, and, presumably from the description, Carter's.—E. B. S., *Hardwick*.

Mulching.—Attention must be given to this during the next few weeks in order that evaporation may be reduced and watering lessened. This is particularly needed in regard to trees growing against walls. In mulching, the first thing to be done is to remove all weeds, afterwards lightly pricking up the surface-soil with a garden fork. Any newly-planted trees or those that have failed to set crops this season should only be mulched with light, strawy materials, rich manure tending to gross, unfruitful wood. Trees bearing good crops of fruit will be greatly benefited by a liberal dressing of partially-decayed stable-manure, giving a good

TREES AND SHRUBS.

HYDRANGEA PANICULATA.

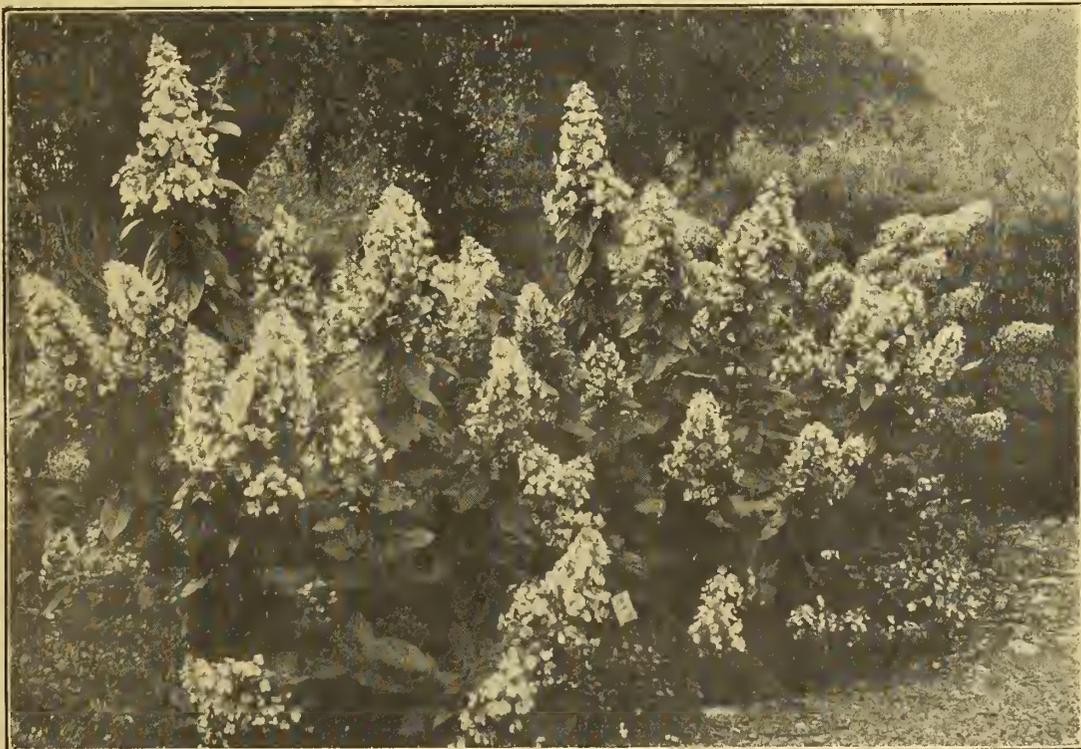

This is better known in gardens by the variety grandiflora than by the type. It is of Japanese origin, and forms a bush up to 6 feet or 8 feet in height. The leaves are large, and the growth strong, and the flowers in upright terminal panicles, each 6 inches to 9 inches long, and 6 inches through. The blossoms are white, and borne from early August until October. A considerable number of both sterile and fertile blossoms composes each inflorescence. A good idea of its decorative value may be gleaned from the accompanying illustration. The variety *H. p. grandiflora* is distinguished from the type by reason of the inflorescences being made up of sterile flowers only. When growing in rich soil, the panicles of bloom may be anything up to 18 inches long and 9 inches in diameter. It is grown largely for forcing. Both the type and variety may be

also made use of the Cedar for washing-troughs in the laundry, made twelve years ago.

THE BLUE WILLOW.

(*SALIX CERULEA.*)

THERE is some doubt as to which is the best Willow for bats, for of the several kinds that grow into tree size in this country one is well in advance of the others for the manufacture of bats. It is fairly common in Essex, Norfolk, Hertfordshire, and other eastern counties, growing about the margins of streams and in hedgerows, and differs from other Willows by its erect branches, which bring about an almost pyramidal habit, and by its moderately smooth or only slightly-fissured bark. There are other minor differences, but the habit is the most conspicuous feature. Moreover, all the trees in cultivation are females, which suggest that all may have been raised from cuttings of one original tree. It was at

Group of *Hydrangea paniculata* in the garden at Hillbrook Place.

soaking with clear water directly after the mulch has been applied. Future waterings to fruitful trees may consist of clear water and liquid-manure from the farmyard applied alternately. If the weather during the summer is hot and dry it may be necessary to mulch a second time.—G.

Infested Vine (*L. Hants*).—The Vine-leaf sent seems to be badly infested with thrips, a very minute insect that establishes itself in great numbers on the undersides of the leaves, and subsists on the sappy matter of the leaves, fairly sucking them dry. These pests are generally found on Vines where the atmosphere is very dry. You may do some good by syringing the leaves freely with a solution of Sunlight-soap or of Gishurst compound and flowers of sulphur well stirred in, but the house must have the floor damped, and a close, moist air be generated for a few days and nights to endeavour to check the ravages of this troublesome little insect. Use the syringe freely night and morning.

Strawberries.—Those who are fortunate enough to have a late batch of plants in pots in houses or frames may find them valuable, as indications point to a late season in respect of the outside Strawberries. If not already attended to, young beds intended to fruit during the present year ought to be hoed over, and, after being dressed with soot to destroy slugs, mulched. If possible, the litter ought to be rather long, so that by the time the fruit is ripening the rains may have washed the shorter and manurial parts well in, leaving the straw clean for the fruits.

cut well back to within a few buds of the old wood in February. A good dressing of manure in May does good, while, if the young shoots are thinned out when 6 inches long, finer flower-heads result. The type may also be grown without pruning, but the flower-heads are smaller.

Use for Cedar wood.—Those who have fallen Cedars of Lebanon may find some useful suggestions in the following note from Mr. H. C. Baker in the *Gardeners' Chronicle*:—"For many years I have experimented with home-grown timber. From experience I find that the wood of the Cedar of Lebanon is very valuable for general estate purposes, such as rafters, purlins, stud work, wall plates, and tie beams. It is very durable and not liable to warp. I have also used it for floorboards, mangers, and partitions in cow-stalls and stables; also for joinery work. I have two vinery doors which were made 22 years ago, one of Cedar, the other of Corsican Pine, which to-day are absolutely sound, showing no sign of decay. I have

one time thought to be a variety of *Salix alba*. The leaves of the two trees are certainly much alike, but differences in other ways, particularly in habit and vigour, give credence to the theory put forward by Professor A. Henry that it is a hybrid between *S. alba* and *S. fragilis*. Although the tree is most common in the eastern counties, there is no reason why it should not be grown elsewhere, for it grows quite well in other parts of the country, and it is probable that the timber would preserve its valuable qualities wherever grown provided growth is rapid. Some difference of opinion exists as to the

KIND OF CUTTING, many people recommending that straight branches each 6 feet to 15 feet long, and even 20 feet have been tried, should be used and inserted 2 feet to 3 feet deep in the position the trees are to occupy. This custom has doubtless arisen from the fact that people wishing to secure trees with the minimum of trouble inserted large cuttings in order that the young shoots should be out of the way of cattle. Ordinary cuttings 1 foot

long planted in a nursery answer quite well. In the first year shoots 4 feet or more long are formed. If strong these can be allowed to grow, but if weak they should be cut back to within a bud or two of the base and a strong shoot encouraged the following year. Such young trees must then be taken to permanent places, for they do not transplant very well if left too long in nursery quarters. Trees raised from small cuttings usually produce more perfect timber than those grown from large cuttings, for in the latter case defects often occur in the centre of the trunk. Moreover, large cuttings at the outset are expensive, for they represent several years' growth from pollarded trees, whereas small cuttings can be made from shoots one year old, and several cuttings can be made from one shoot.

One point to be observed in the culture of this Willow is the preservation of a clean trunk for a height of 15 feet or 18 feet. In order to effect this, side shoots must be removed carefully whilst quite small. Here the value of the large cutting is seen, for the removal of side shoots does not cause it to become top-heavy, whilst the too rapid removal of side shoots from young plants grown from small cuttings may cause the trees to draw up so rapidly that they cannot maintain an erect position without the aid of stakes. Good can sometimes be done, however, by shortening the leader and allowing a new one to take its place. There are other hybrid Willows of the same parentage, notably *S. viridis*, which is very similar in many respects to *S. cœrulea*, but is of looser habit, with more pendent secondary branchlets. Its wood is not so valuable as that of *S. cœrulea*. When selecting cuttings it is therefore very necessary that the purchaser should convince himself that they are from trees possessing the stiff, erect, narrow-headed habit combined with a fairly smooth bark, which is characteristic of the true Blue Willow. The value of the wood of this tree for several years past has been in advance of that of any other British tree, and it is likely that a good price will be maintained for some years to come. Even a few trees planted upon a small estate and left to grow on quietly will, with ordinary good fortune, prove valuable in twenty years' time. D.

CATTLE AND YEW.

THE information given in notes under "Law and Custom" is always of a helpful and practical nature and in terms easily understood, but yet occasionally illustrating the difficulty in coming to a conclusion in matters of dispute. In the vexing question, for instance, of cattle and Yew, if the trees were planted close to the boundary-line between two properties is it essential that the owner of the trees should keep them trimmed out of the reach of cattle on adjoining premises, and does the reaching over constitute trespass if the animal itself is not outside its owner's property? The object of this note, however, is hardly a query in the matter of law, but rather to suggest that the result of the eating of Yew by cattle is of so variable a nature that it is extremely difficult to tell when and how it is injurious. Is it at some particular stage in the growth of the tree or are there times when the animal is specially affected by it? I have known cattle eat it often with impunity, and so far as sheep are concerned, I remember a big, old Yew some 20 feet in circumference, with a thickly-feathered stem, in a little village churchyard into which the animals were occasionally turned. They ate all the young growths as high as they could reach, and I never heard of any ill-effects from

the same. On the other hand, we often hear of both horses and cattle dying (as certified by veterinary surgeons) from the effects of Yew-poisoning, which makes the whole matter, as above noted, very difficult of solution and well worth consideration when one remembers the many private places throughout the land in which the Yew is found in some shape or form, and often in close proximity to park and meadow land in which cattle are grazing.

Hardwick.

E. B. S.

BERRY-BEARING AUCUBAS.

HARDY berry-bearing shrubs, especially those whose fruit when ripe is of a bright colour, are always esteemed, and deservedly so, for they enliven our gardens through the dull season of the year when there is little that is attractive. When the pollen-bearing variety of *Aucuba japonica* was first introduced, it was justly looked upon as a great acquisition, as by its agency not only would the old well-known spotted leaved berry-bearing form become clothed with bright red berries, but green varieties as well. Yet this appears not to have been realised. Strange as it may seem, there are very many gardens, both large and small, in which the pollen-bearing variety has not been planted, or if so, in such limited numbers as not to render fruitful the quantities of fruit-bearing plants which exist. The influence which the presence of the pollen plant exerts is always most apparent on the plants growing nearest it, the fruit of which is more plentiful than that on more distant plants, showing that where large quantities dispersed over considerable distances of ground exist it is necessary to plant the pollen-producing kind in proportionately greater numbers than in most places has hitherto been done. So far as effectiveness is concerned, the green-leaved forms are much more striking than those that are variegated, the contrast between the brightly-coloured fruit and the green foliage being more conspicuous. Some of the seedlings raised have immense leaves, and a few of these may be desirable by way of variety, but those with smaller medium-sized foliage, when combined with the fruit, produce a more pleasing effect. *Aucubas* in their fruit-bearing appear to be less influenced by difference in seasons than many plants, and to derive from the presence of the vast quantities of the common berry-bearing kind the full measure of its decorative value there should everywhere be enough pollen-bearing plants introduced.

NOTES AND REPLIES.

Two beautiful Heaths after snow-storms.—The two most precious Heaths so far as I have tried them are the Southern Heath (*Erica australis*) and the Portuguese Heath (*E. lusitanica*). They have for several years withstood the winter climate of Sussex and the recent snowstorms, and in some ways are the more beautiful for having been tossed about. *E. australis* is perhaps the most beautiful of all the spring-flowering Heaths, and is so good that I like to have it in two or three forms and of different ages.—W.

Fendlera rupicola.—Among the uncommon shrubs now in bloom is this *Fendlera*, a native of Arizona, Texas, and New Mexico. It was introduced nearly forty years ago, but, as it needs a hot, sunny climate, it is seldom met with in a satisfactory condition. To be seen at its best here it needs a wall where it gets the full sun, as under such conditions the wood is thoroughly ripened and a display of flowers ensured. This *Fendlera* is a near ally of the Mock Orange. The branches are slender and of a somewhat straggling habit. The flowers, borne on short twigs springing from the wood of the previous year, are white and each about an inch across. Here it flowers, as a rule, towards the end of May and in June.—K. R. W.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

EVERLASTING PEAS.

THE term "everlasting" could never have been more appropriately bestowed, for the life of the old Everlasting Pea seems to be indefinite. The ability of this hardy plant to retain a vigorous life under circumstances which would cripple most other things is remarkable, and therefore it might, I think, be made free use of in places where, as is frequently the case, unfavourable positions for plant growth occur. I have seen this Pea growing with the utmost freedom and blooming abundantly every year where the soil round the roots was almost as hard as a brick from constant treading. I have had it doing well where its roots mingled with those of the Ivy, which very few things can endure. Such a plant, old inhabitant of our gardens though it may be, can never be ignored. By the way, can any of your readers say if this Pea is growing wild in any part of the British Isles? In Loudon's "Hortus Britannicus" it is placed among native plants. Loudon has two Everlasting Peas—*L. sylvestris*, an inhabitant of moist woods in Britain, and *L. latifolius*, a native of England. In former days I had a good deal to do with our native Flora, and came into contact with botanists with a thorough knowledge of our native plants, but I never heard one say that he had found, or even heard of, this species growing wild. The white variety is well known as one of our finest hardy plants, simply invaluable for furnishing an abundance of the purest white flowers at the lowest possible cost. This Pea was at one time to a very large extent lost to flower-growers. I suppose that many plants were destroyed in the alterations made in gardens when bedding out and sub-tropical gardening became a craze.

It must have been when GARDENING ILLUSTRATED was some two or three years old that a friend discovered an old specimen of it in the garden of one of our village inns. When the innkeeper left he secured the root and gave it a good place in his garden, where it made a fine show and ripened a big crop of seeds. These seeds were sown, and about a thousand seedlings raised, of which about three-fourths were true, and these the following year were distributed over the British Isles. I raised many hundreds in later years, and there was always about the same proportion of plants which reverted to the type. At one time I had nearly a thousand of the pink form, and, which showed considerable variety of colour, some being much brighter than the type, and others in varying shades of pink. I have always been sorry that I did not select from them and propagate them from cuttings. I was going to destroy them, as they were taking up so much space, but there came a sudden and remarkable boom in this Pea, and in less than two months they passed from my hands into gardens in all parts of the land, and I suppose that they are still in existence. I can believe that ninety-five per cent. of those Peas, both pink and white, are yielding pleasure to their owners. Of how many hardy flowers could so much be said?

One thing that I hoped for, and, in a measure, expected, never came to pass. I thought that among the quantity of seedlings—some thousands from the white variety—a delicate flesh-coloured one might have appeared, which would have formed the starting point for a series of variously-tinted varieties, but nothing of the kind came to light. There were quite

pale pink flowers, but the border-line between pink and white was never bridged. That this will come one day I am convinced, as there comes a time when by reason of some subtle influence one particular plant breaks away from the fixed character, which has endured through countless generations, and then comes almost infinite variety. Only those who have passed half a century in gardening can fully realise what a simple break, a slight deviation from the type has effected. The new white variety, White Pearl, has flowers considerably larger than those of the old form, but whether this increase in size renders it more effective I have not

a person of that name. It is pretty and very distinct, but weather-sick. It is best at home rambling over low-growing shrubs, when the flowers are partly screened from hot sun and heavy rainfall. Grandiflorus would be a good thing if it flowered more freely, and Sibthorpi cannot be termed a first-class hardy plant unless it grows much more freely with others than it does with me, and the colour of the flowers is not so good as that of the common kind. These are all the Everlasting Peas I have grown, and I see no others offered in trade lists. What about such kinds as pisiformis and mutabilis, introduced respectively in 1729 and 1825 from Siberia, californicus

DAFFODIL FAIRY.

This is an instance of a curiously inappropriate name. It is really one of the largest Daffodils ever raised, but though a giant, it is wonderfully refined and perfect in shape. The huge recurved trumpet is a pleasing shade of deep yellow, the perianth slightly lighter in tone. It is a first-class variety for the border, being a vigorous grower and flowering very early; also highly suitable for pot culture. It ought to be more popular, seeing the price brings it within the reach of all.

J. R.

AMONG THE HARDY FLOWERS.

SPRING PHLOXES.—These are doing well with me this year, but I find that they flower better when high up than in low-lying parts of the garden. In the latter they appear to suffer more in winter, and are often browned by frost and cold winds when those in the higher parts are unharmed. This is a point worth considering, as these Spring Phloxes are so lovely in every way that all who love the early flowers enjoy them. I am referring here to those of the subulata or setacea section, such as atropurpurea, The Bride, Vivid, and others of the same class. By the way, I have occasionally seen it said that Vivid is not so hardy as some of the others. My own experience confirms this.

OXALIS ENNEAPHYLLA.—It is little wonder that people go into ecstasies on seeing Oxalis enneaphylla in bloom for the first time. I have it now finely in flower. The other day a friend to whom I had written extolling Oxalis enneaphylla sent me a quotation from a book on rock plants, which contains this reference to the Oxalis. I think it is worth repeating. It says that it is "a garland of pearl-white Couvolvulus flowers nestling among crinkly, glaucous-grey leaves." I like the description, but the flowers are not quite so big as the quotation would convey. They are of a lovely satin-white, and the leaves are beautiful in themselves. I was told that this Oxalis preferred a cool spot, and I gave it this, planting in light loam and leaf-soil, with happy results. I was lucky enough to see the rose-coloured variety of O. enneaphylla in bloom, and I like it much. There is room for both.

THE PEARL BERRY.—My plant of Pearl Berry has been killed. It is not surprising that it has succumbed, as it is not to be looked upon as absolutely hardy. It is well that it has such an attractive and admirably descriptive popular English name, and that we are not compelled to use the formidable one of Margyricarpus setosus.

THE WELSH POPPY.—There is an old saying that "one year's seeding makes seven years' weeding." This is surely true of the single Welsh Poppy, Meconopsis cambrica. I must disagree with a writer who tells us that this plant is "a dreadful weed, but you may grub it up fairly easily." With the first part of the verdict I agree so far, but I demur to the statement that you can grub it up fairly easily. It may be true enough with young plants in an open border, but when they are a year or two old it is difficult to remove every bit of the root, and, when any piece is left, the Poppy is almost as troublesome as any Dandelion. Some of the perennial Poppies are just as bad. They seed so freely and are so difficult to eradicate that they are perfect old men of the sea to one who is fond of flowers and who finds that the care of some treasures is much increased by the difficulties of keeping down

Narcissus Fairy.

been able to prove. This variation seems, however, to point to an inclination to break away from the form which has existed unchanged for a good many years.

The list of Everlasting Peas is not a long one, and as far as I am aware no new species has been introduced in recent years. We have the species which is now grown under the name of Drummondii, but how it came by this name I cannot understand, as seventy years ago it existed in English gardens under the name of rotundifolius, and is thus listed by Loudon. There can have been no good authority for the change of name. I can only think that at one time it almost dropped out of cultivation and was brought into notice again by

in 1826, polymorphus in 1824 from Missouri, venosus and decaphyllus in 1829 from North America. All these were evidently in cultivation in 1850, when the "Hortus Britannicus" was published. Where are they now? They may be in cultivation, here and there there may be old specimens in some of those old-fashioned gardens which have never been modernised, but although I have been a diligent reader of gardening papers for a period of forty years I cannot call to mind that I have ever seen any mention made of them. Coming from Siberia and North America they must have constitutions strong enough to resist the vicissitudes of our English winters.

J. CORNHILL.

Meconopsis cambrica, *Papaver pilosum*, and one or two others. The Oriental Poppy is less obtrusive.

AN AMATEUR OF HARDY FLOWERS.

THE DOUBLE-FLOWERED NARCISSUS POETICUS.

WHAT is the secret of the successful flowering of this? I have planted what appeared to be firm, well-ripened bulbs in different situations, and often failed with them, but this season a dozen rather small bulbs turned out of a pot in which they had been standing from late May until September, and, just put into ordinary soil, are each showing a fine flower, which makes one think that the answer to the above question may be found in extra-ripened bulbs. If this is so it may be well to take the trouble to acquire them, the flowers being so acceptable alike for their beauty, scent, and lateness; also their great endurance outside in a slightly shaded position and in a cut state. I thought of leaving a portion of the small colony in the ground and lifting and storing away the remainder until next planting time to note how they behave another season under the different treatment.

It is a little strange that the double form should be difficult when the better known single type is so easily grown; indeed, of all the *Narcissus* family there is nothing that adapts itself better to naturalisation, and certainly nothing that gives in the course of years such a wealth of flower from the single bulb. It should be planted rather deeply in light soil. The question of the naturalisation of *Daffodils* is very interesting, and one never likely to be quite satisfactorily mastered; that is, it is a matter about which we are always learning, and likely to have to learn, in connection with the many varieties annually raised. Some of these may in time occupy as prominent a place outside as the old favourites, while others are only likely to prove satisfactory with annual lifting and replanting. E. B. S.

Hardwick.

NOTES AND REPLIES.

Monardas.—The crimson whorls of *M. didyma* are for a time attractive, and the odour of the plant is agreeable to many. But when all is said and done, I think *Monardas* are better fitted for the edges of shrubberies and similar places than for the border. A form not worth room, in my estimation, is the white variety *M. didyma alba*, which I heard highly praised the other day. Other sorts, such as *M. elegans* and *M. Russelliana*, are merely variations of *M. didyma*—no better and no worse. One thing is certain, if *Monardas* are to be seen to advantage they must be planted in clumps of considerable size, and they take up more space in this way than the most of us feel disposed to allow to them.—KIRK.

Anemone coronaria (Poppy Anemone).—A large bed of this has made a brilliant display for some weeks past. The plants are easily raised from seed sown as soon as ripe. Make the seed bed of a fairly porous soil in an open part of the garden. The surface before sowing should be made firm and level; if dry, moisten the soil before the seed is sown. It is a good plan to scratch the surface of the bed with a worn down garden broom immediately before sowing, which should be done broadcast, the seed being then covered with a thin sprinkling of sandy soil. After this, make the bed smooth and shade it from the sun until the seedlings begin to appear, when the shading must be removed. The bed must never be allowed to get dry until the young plants have finished their growth or they will wither prematurely.—F. W. G.

Hardy-plant borders.—These are now highly interesting. *Doronicum Harpur Crewe* is always striking at this season, and clumps of *Dielytra spectabilis* are very free. Occasionally, this fine plant is marred by untoward frosts, but, so far, it has escaped during the

present season. *Aquilegias* of the old garden type are in fine flower, and *Epimediums* are not unattractive. *Pæonies* are on the point of expanding their buds, and *Irises* of sorts continue to be effective. *Pyrethrums*, both single and double, will not be much longer delayed, and *Lilies of the Valley* are in full bloom in the more favoured situations. Bulbous plants add to the attractions of the hardy plant borders, the later *Narcissi*, although rather knocked about by recent storms, being noteworthy. *Anemones*, both *A. stellata* and *A. coronaria*, yet remain in good order, and in the latter case will be prolonged until nearly midsummer. While considerable quantities of bloom may yet be seen on *A. stellata*, the display may be regarded as practically over for the season.

GARDEN FOOD.

FRUIT SALADS.

WHEN the weather is hot there is nothing so wholesome as fruit, either in its raw or cooked state. I prefer fruit to be perfectly ripe, and then to be eaten plain or made into a salad. In fact, when fruit is plentiful I generally serve fruit as a salad instead of a sweet. It is quickly prepared and needs no cooking, and if eaten with crisp biscuits is in itself, I think, sufficient for a mid-day meal. A mixed fruit salad is always nice, and the different fruits as they come into season can be blended, and form a delightful whole. Some prefer a mayonnaise dressing, but I think the mixture of fruit juices, with sugar and lemon-juice, makes the nicest method of making fruit salads. They should always be prepared at least an hour before being served, as this allows the juice to run from the fruit and blend before it is eaten. A delicious mixture is to take two Oranges, two Bananas, $\frac{1}{2}$ lb. red, cooking Cherries. (The Kentish Cherry is extremely nice in a salad, but it must be quite ripe and fresh.) Cut all the fruit into slices, after peeling and stoning; arrange in layers in a deep salad-bowl, sprinkling a little Lemon-juice over each layer, and a moderate quantity of castor sugar. Take $\frac{1}{2}$ lb. nice large Strawberries and remove the stalks, cutting each berry into quarters. Dip into the sugar and arrange prettily on the top of the contents of the salad-bowl. Sprinkle a little Lemon-juice over the whole and set aside in a cool place for two hours.

RASPBERRIES, with the addition of Cherries, make a nice salad, and as a contrast two Apples can be chopped and added to the mixture. The Cherries should be stoned and halved. Sprinkle a moderate allowance of sugar over the fruit before stirring it together, and the juice of a Lemon can be added to give the necessary tartness. If, however, the Cherries are sour, this can be omitted. In no case should ordinary vinegar be used when making a fruit salad, as this destroys the flavour. Some housewives like the addition of a tablespoonful of port wine, but the flavour of the ripe fruit, with the addition of a little sugar and fruit juices, is all that is required to make a perfect summer dish.

Chopped Mint is useful to vary the flavour of Orange and Banana salad. Cut the pulp of six Oranges into dice, sprinkle with two tablespoonfuls of castor sugar and the juice of half a Lemon. Chop some Mint finely and strew a tablespoonful on top of the salad just before sending to table. Apples can be used in this salad.

RED AND WHITE CURRANTS, Cherries, and Oranges make another nice combination. Grapes, both purple and white, mixed with an equal quantity of chopped Pineapple and Cherries and sprinkled with sugar, with or without Lemon-juice, are very good. The quantities of each individual fruit can be varied at will, some people

preferring a greater proportion of one particular kind to having an even mixture. The juice of any acid fruit will do just as well as Lemon-juice, Cherry-juice being extremely good. H. T. C.

TWO TOMATO SALADS.

SELECT large, round Tomatoes with very fleshy centres. Do not peel them, but cut off the tops, leaving about two-thirds of the fruit intact. Scoop out the seeds, and then cut the outer part of the fruit into two rows of petals. It requires a little practice to do this perfectly, but the effect is extremely pretty when carefully done. Take the centre of the Tomatoes and mix with the least suspicion of Onion-juice (it must be more a suggestion of Onion than the flavour), the same quantity of chopped heart of Lettuce, salt and pepper to taste, and mix. Fill the Tomato roses half full of this mixture, mask with a good, stiff mayonnaise, and arrange some tiny shreds of Celery to look like the tops of stamens. Toss some shredded Lettuce in a little mayonnaise and place lightly on a dish. Arrange the Tomato roses on this and serve at once.

Select a perfectly-shaped Cabbage Lettuce with a firm, white heart. Take five of the most perfect cup-shaped leaves and place on a bed of shredded Lettuce arranged on a glass dish. Cut the tops off five Tomatoes and scoop out the seeds. Place the Tomato cups in the centre of the Lettuce leaves and fill with a mixture of cold boiled green Peas and cubes of cold New Potatoes. Mask with a good mayonnaise. Garnish the shredded Lettuce and slices of Tomato and tiny balls of cream cheese, with little piles of thick mayonnaise at intervals. Serve at once.

H. T. C.

NOTES AND REPLIES.

Apple Beauty of Kent.—In a recent note by Mr. Taylor, of Hampton, reference was made to this Apple. I was glad to see it mentioned, for it is unquestionably a good keeping sort and at any period an excellent cooker, while it is also valuable for eating after, say, February. Previous to that month the fruits seem too sharp in flavour and firm in the flesh to be enjoyed as a dessert variety—at least, to my thinking. It is acknowledged by the Royal Horticultural Society in their list of varieties. It is, here in Highgate, a good doer and bearer. I send a specimen showing the condition the second week in May.—C. TURNER.

[A very good sample of this *Apple*. The variety, however, is at its best during November, and with careful storing may be had in good condition up till March. When kept so late as May the flesh becomes mealy and wanting in juiciness and flavour, as in the case of the specimen to hand.—Ed.]

Haricot Beans à la Lyonnaise.—Soak a pint of Haricot or Butter Beans for at least twelve hours, then look them over and remove any that are imperfect. Put the Beans into a saucepan of cold salted water, bring the latter gradually to boiling point, and then let it simmer gently for three hours. At the end of that time ascertain if the Beans are tender, and accordingly pour off the water. When they are ready cut two Onions into very thin slices and fry them in butter until they are a golden brown; then add half a pint of good brown sauce and the cooked Beans. Cover them with a greased paper and let them simmer in the sauce for about fifteen minutes. Just before serving scatter a heaped teaspoonful of chopped Parsley over the Beans.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

**THE GROMWELLS
(LITHOSPERMUM).**

LITHOSPERMUM PROSTRATUM is now at its best, falling over the edges of low retaining-walls and on the flat in well-drained soil forming masses of vivid Gentian blue. Planted in free soils it grows rapidly and soon covers its allotted space. If planted where it escapes the mid-day sun, especially on hot soils, growth is more free. Heavy soils should have peat and sand well incorporated with them, and where lime is present a mixture of good loam, peat, and sand should be provided and the natural soil removed. A great favourite wherever grown is the variety

L. P. HEAVENLY BLUE (see illustration), in which the flowers are lighter in colour than in the type, while the growth is also more compact.

coloured of all the Gromwells, and should find a place in every garden. With the craze for newly-imported plants we are inclined to pass by some of our beautiful native plants. This, the only one useful for cutting, will succeed in soils of a lime or chalk nature, for in such it is found, though rarely, wild in the south of England.

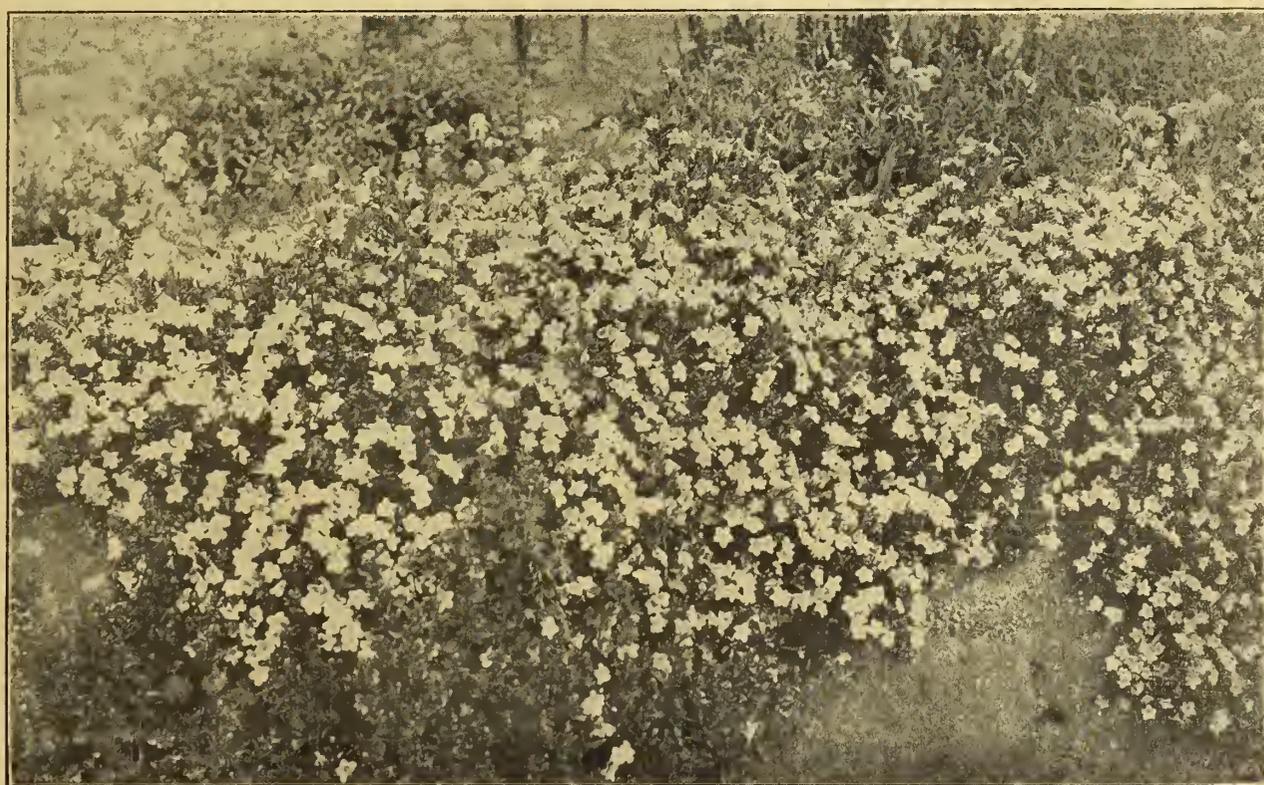

All of these strike fairly easily from cuttings inserted during late summer in a close frame, although they take a little longer than most things. E. M.

INDOOR PLANTS.

PASSIFLORAS.

WHILE there are very many subjects suitable as climbing plants for the greenhouse it is questionable whether any family is more generally useful than the Passion Flowers. One variety or another may be found suitable either for the greenhouse

with its carmine blossoms, then these drop, a period of growth ensues, and this is followed by a renewed display. This continues throughout the season and adds much to the interest of the variety. P. princeps is an excellent sort with vivid scarlet flowers of medium size. P. alata I do not much care for on account of the greenish tint which mars the rays of the large, crimson, slightly fragrant blooms. P. amabilis is very free, the flowers bright scarlet with a white corona. P. fulgens is also a scarlet-flowered sort, the blooms freely produced and of medium size. P. Buonapartea, with its red, white, and blue flowers, is a fine variety, but it appears to require grafting upon a more vigorous sort to succeed. Of all the Passifloras none, to my mind, is so handsome as P. quadrangularis. Its blooms are beautiful, but almost indescribable, being delicately fringed and fragrant, and combining the colours of white, red, and violet. If these are artificially fertilised the seed-pods, in

Part of a group of Lithospermum prostratum Heavenly Blue.

L. PETREUM is a small sub-shrubby plant well suited for the rock garden. The flowers, which appear in June, are of a beautiful deep blue colour, and are freely produced at the ends of the young lavender-like growths in round, drooping clusters. It is sometimes known as Moltkia petraea.

L. ROSMARINIFOLIUM is a charming shrubby species which flowers earlier and is of a lovely pale blue. In habit it resembles a small Rosemary, hence its name, and is more tender than the foregoing kinds, therefore it should be planted in gritty soil on a warm and protected part of the rock garden. Native of Greece and Italy.

L. PURPUREO-CÆRULEUM, a native kind, bearing flower-spikes each about a foot in height from the centre of the plant, each carrying three dozen or more deep blue-purple flowers. Prostrate, barren growths, each about 2 feet in length, are produced from the base of the plant. These strike root at the tips and flower the following year. This is, perhaps, the most deeply-

from which the frost is barely kept, the warm greenhouse, the intermediate house, or the stove. The blooms of all are equally charming in their way, and, in the majority of instances, their culture calls for no special skill. In all cases, if potted—or, what is better, planted out—in good, sound loam with plenty of leaf-mould and a sufficiency of sand, luxuriant growth and plenty of bloom soon follow. For quite cool houses nothing equals P. cœrulea, practically hardy out of doors in some favoured parts. Another good greenhouse sort is P. c. racemosa, with abundant reddish-purple blooms. A moderately free grower is P. Belloti, of hybrid origin, which produces its pink and white flowers all through the summer and autumn months.

Of those Passion Flowers which require the heat of the stove, one of the very prettiest, as well as one of the most free-blooming, sorts is P. kermesina, which has rather a noteworthy way of flowering. For a week or so the plant will be covered

a temperature of 80 degs. to 85 degs. during the day and not less than 70 degs. at night, soon swell and attain to a weight of 2 lb. or over. These are edible, and although to many they are insipid, yet by others they are appreciated. These fruits are known as Granadillas. If it is intended to fruit P. quadrangularis, all the shoots that are required must be permitted to grow throughout the season without stopping. W. McG.

NOTES AND REPLIES.

Sowing Palm seeds.—A recent note in GARDENING ILLUSTRATED stated that this is a very suitable time for sowing Palm seeds. This is quite correct so far as it goes. A most important consideration, however, is to remember that seeds of some Palms do not retain their germinating power for any great length of time, so that my advice would be to sow the seed whenever it can be obtained, whatever the season of the year. For the stronger-growing Palms, such as Kentias,

Latania borbonica, *Chamærops*, etc., I prefer a soil largely composed of loam lightened by a little well-decayed leaf-mould and sand. Some advise the sowing of the seed singly in small pots, which is all very well when but a few are to be dealt with, but in the case of larger quantities they are best sown in pans or shallow boxes. The seedlings must be potted off singly as soon as the first leaf develops, otherwise the roots are apt to become entangled, and, if damaged in any way, the young plants sustain a decided check. Potting, too, must be carefully done. Palms of a more delicate nature, such as *Cocos Wedelliana*, *Geonoma gracilis*, and some species of *Thrinax*, are benefited by a mixture of peat in the soil in which the seeds are sown, and also in potting them later on.—W. T.

Rex Begonia.—Plants from leaf-cuttings, not quite three months old, and now in 3-inch pots, are making excellent stuff, some of them carrying as many as fourteen well-developed leaves. These make useful plants for vases, and stand a good deal of knocking about, while, should a few plants be lost, their value is not great, and they can be easily replaced. I prefer plants from leaf-cuttings to those obtained by division, and if they are given stove heat for a time progress is rapid. Like old-fashioned plants generally, the *Rex Begonias* are under a cloud at present, but they have their uses. Large and handsome pieces can be grown in 6-inch or 7-inch pots, although I prefer smaller specimens.—W. McG.

VEGETABLES.

CURLED KALES.

I do not think we have any better vegetable during the late winter than the true Scotch Curled Kales, these, when properly cooked, being vastly superior to some of the Russian sorts. A great deal depends upon the cooking. In March, when well cooked, Kale is more like Spinach in June, owing to its tender nature and good flavour. The Kales in some seasons are better than in others, and this year the cold snap we had in February and the early part of March had made this vegetable of greater value, and also, in my opinion, much improved in flavour. Frost, if not too severe or long lasting, gives this hardy vegetable a mild flavour. Owing to its hardy nature the plant does not suffer much if well grown. I have seen Kales totally destroyed. For instance, in the severe winter of 1895, I had every plant killed in February and early March. Since that date I have never relied upon the tall Kales, as though quite equal in quality to the dwarfier section, I find they are more readily affected by frost—I mean the stem portion not protected by leaves. In the winter named the stems were so badly injured by frost that the heads toppled over and the crop was ruined. Of the dwarf section there is no lack of excellent varieties. It is difficult to beat a good strain of the old Scotch Dwarf Curled and the excellent Extra Curled Scotch, which, though of stronger growth, makes a grand head, the leaves being finely curled and freely produced. At the same time it is one of the hardiest of all. For latest supplies I have found the Dwarf Late Curled all one may desire. It is quite good well into April and will be found of great value for latest supplies. The three varieties named will be found ample.

It is a mistake to sow too early, but much depends upon the locality. For instance, I have sown in the south when April was well advanced, but in the north I would sow two or three weeks earlier. Give plenty of room in the seed-bed and do not allow the seedlings to get weak or too large. I always put out quite small plants and get excellent results if the work can be done in showery weather. If land is not available far better transplant in rows

6 inches apart, and later on lift into their growing quarters, than allow the seedlings to suffer. If an earlier supply is desired, say before the new year, I would advise two sowings, one early in March and the other at the time advised above. The quality of the earlier lot will not be equal to that of the later one. These hardy Kales are not fastidious as regards soil or situation, and do remarkably well on a stiff loam if well worked. In all cases they should get an open quarter, and at least 2 feet between the plants, or even more if land is available, with the same distance available between the rows.

Of late years there has been a most useful addition to this class of vegetables—a Drumhead Kale. This is excellent for early winter, and what makes it more valuable, it is a free grower in poor soils. If the broad leaves of this Kale are stripped the green portion when cooked is equal to Spinach, while the midrib makes a splendid vegetable cooked like Asparagus. This remark applies with equal force to the Scotch Kales. At this date a nice dish can be had by stripping the green portion of the leaf from the midrib. This, cooked in a shallow pan, and in not too much water, but kept on the boil, makes a delicious vegetable. M. F.

GARDEN LABOUR DIFFICULTIES.

Owing to scarcity of labour many will have to vary their system of vegetable culture. I should hesitate to advise anyone to neglect the preparation of the land, but much depends upon the work done in the past. If well done previously, it is surprising what may now be done with quite ordinary culture. In many gardens, especially near towns, manure will be a costly item, and in many cases must be done without, and in some gardens with advantage. In such cases deep culture will be more beneficial, and it is easy to feed growing crops with artificial manures later on. In many gardens at times there is a surplus of soft green crops that are past their best, and which will be of great benefit if dug in. Quite recently I saw a small private grower worrying because he could not get Parsnips sown owing to the unfavourable weather. The best Parsnips I ever had were sown about the first week in April, and were large enough for anyone who studied quality. We have in these war times to do the best we can. Take the Pea crop, for instance. In many gardens stakes will be difficult to get, and this want can readily be met by growing dwarfier varieties. I have often grown 3 feet high varieties, and these, if they have their points removed when about 2 feet high, will branch freely and give fine crops with very little support. For this work the strong, double-podded sorts are best, and there is a wide selection, some of our best quality Peas being in this section. The same remark applies to Runner Beans. This year Bean-sticks will be very scarce, and may quite easily be done without by stopping the plants when from 12 inches to 18 inches high. If this is done, excellent crops may be had without stakes, and the pods will be large enough for all purposes. It may be asked, why not grow dwarfs, and avoid the labour of stopping. Grow dwarfs for an early crop, but as the dwarf sorts age so quickly and lose flavour the Runners are more profitable. In the case of Celery, one can lessen labour by sowing late on a warm border and planting direct into the growing quarters. In this way there are a considerable saving in labour and much better results than by sowing seed in strong heat and pricking out the plants into boxes before finally planting out. C. R.

ROYAL HORTICULTURAL CHELSEA SHOW.

MAY 23RD, 24TH, AND 25TH.

CARNATIONS.

THESE have been more extensively staged at former shows than was the case this year. In the main the types of the Perpetual-flowering race were those on view, Mr. Douglas alone showing border varieties. His most remarkable variety was Sweet Anne Page, a fancy with creamy-yellow ground heavily striped with lilac. It gained an Award of Merit. Elizabeth Shiffner (apricot), Bookham White, Bookham Clove, Deloraine (scarlet), and the fine, white ground, fancy Mrs. A. Brotherston were others of note. Mr. A. F. Dutton, Iver, Bucks, showed these flowers in baskets and other receptacles, the new cerise-coloured Louvain being excellent.

Messrs. W. Wells, Limited, Merstham, had a particularly good lot in which Pink Perfection, Aviator (scarlet), and Lord Kitchener (pink) were noted among many others. In the small group from Misses Price and Fyfe, Birch Grove, East Grinstead, the two more distinct were the mauve and rose fancy Kenneth and the cherry-red Malcolm.

Messrs. Allwood Brothers, Haywards Heath, staged many fine varieties. Those justly popular sorts Mary Allwood and Wivelsfield White constituted a splendid background over which suspended baskets of May Day were very fine. Two of the newer pink-flowered novelties, Nora West and Bedford Belle, were in this group, as also Bishton Wonder, a strangely-coloured fancy sort.

Mr. H. Burnett, Guernsey, had a fine group of flowers of high quality. Mrs. W. B. Clode is ever popular, while such as Mrs. C. F. Raphael, R. F. Felton, White Chief, Mandarin, White Wonder, Marmion, and others were also good. A notable novelty was the rich cerise-coloured Nikko, a full and shapely sort with pronounced fragrance.

Messrs. Stuart Low and Co. contributed a considerable variety of Carnations, including the Malmaison variety Princess of Wales and Mrs. Myles Kennedy, of deeper colour. Messrs. William Cutbush and Sons, Highgate, N., showed an extensive assortment amid Palms and Ferns, arranging the whole on the ground. The fine scarlet King Arthur and Highgate were two of the more notable sorts.

ROSES.

Roses have ever been an outstanding feature at this exhibition, and this year, despite the exceptional circumstances and thanks to the enterprise and zeal of the Rose growers, they were not one whit inferior to those of normal times. Conspicuous above all else, as much by the towering pillars as by the unique display of brilliant scarlet flowers, was the glorious group of Scarlet Climber shown by

Messrs. W. Paul and Son, Waltham Cross. Of undoubted vigour, fine stature, and remarkable for its large flowers and rich display, it is truly a great Rose. Elsewhere the firm had a group of the best, backed by Wichuraiana and other Roses.

Messrs. Alex. Dickson and Sons, Newtownards, showed their new variety Molly Bligh, which gained an Award of Merit. Midway in colour between Mme. Abel Chatenay and Mrs. Laing, it partakes not a little of the former in style, with somewhat of the fulness and strong reflexing tendency of La France, and withal a rich and glorious perfume—hence worth growing. Messrs. Wm. Cutbush and Sons' con-

tribution to this section comprised *Polyantha* and nearly allied sorts.

Messrs. Hobbies, Limited, Dereham, had a group of exceptional richness and variety; Jessie, Annie Müller, Elen Poulsen, and Excelsa, the last a wonderful mass of colour, contributing their quota, with others, to an imposing display.

Messrs. Piper and Mr. J. C. Allgrove exhibited the single-flowered Chinese *Rosa Hugonis*, a delightful species with creamy-yellow flowers rather larger than those of the Austrian Brier. It is very free and the colour-shade new and distinct.

Mr. Charles Turner, Slough, had a nice group in which standards of more than one section were a feature, all admirably grown and flowered withal. Teas and Hybrid Teas were very beautiful, Mme. Jules Gravereau x Snow Queen, and J. B. Clark being noted among others.

Mr. Elisha J. Hicks, Twyford, displaying the varieties in goodly groups, demonstrated their garden worth. This is what we want. The brilliant single crimson Princess Mary, unequalled in colour and rich in fragrance, the new H.T. Mr. C. E. Shea, and Mrs. George Norwood (pink and very fragrant) were some of his good things. *Rosa Moyesi* was very beautiful.

Messrs. Paul and Son, The Old Nurseries, Cheshunt, showed a considerable number of good things, though, as we thought, a little too thickly set. Rayon d'Or, Magnolia, Mme. E. Herriot, Souv. de G. Prat, and Mme. C. Chambard were some notable sorts. The lovely single Paul's Lemon Pillar was charming.

Messrs. Frank Cant and Co., Braiswick Nurseries, Colchester, had a group rich in variety and withal admirably arranged. Rosalie Walker was particularly good among dark sorts; it is also fragrant. Zulu, also dark, is a new bedder. Beulah has pink, Pæony-like, rather loosely-formed flowers, yet delightfully fragrant.

Messrs. G. and W. H. Burch, Peterborough, had a remarkable lot of cut flowers fronting a generous, well-flowered background of *Wichuraiana*. Here, too, overcrowding was indulged in, though blooms of the highest excellence were staged. Mabel Drew, Mrs. Foley Hobbs, W. Shean, Alice Lindsell, Old Gold, Mrs. George Shawyer, J. B. Clark, and Florence Pemberton were all of exhibition quality.

Messrs. B. R. Cant and Sons, Old Rose Gardens, Colchester, showed in their usually good style fine blooms of a high standard of excellence. The more popular sorts were here in abundance, a fine centre being formed of the new white single Silver Moon. As a set-off to this was the brilliant Augustus Hartman, other notables being George Dickson, Mme. E. Herriot, Lady Hillingdon, Autumn Tints, and Hon. Mrs. Grosvenor.

Other Rose exhibitors included Messrs. Stuart Low and Co., Enfield, T. Rochford and Sons, Mr. G. Prince, Oxford, and Messrs. R. J. Barnes and Sons, Malvern.

SWEET PEAS.

These were not exhibited so freely as usual. One of the finer exhibits, the only gold medal exhibit of the occasion, was that from Messrs. Dobbie and Co., Edinburgh. Dora was the outstanding novelty, and, obtaining an award last year in the National Sweet Pea trials, confirmed it on the present occasion by gaining an Award of Merit. It is presumably a bicolor of those delightful tints of pink and cream that are so popular. Dobbie's Orange (rich and pronounced in colour), Dobbie's Frilled Pink and Dobbie's Scarlet, Tea Rose (a lovely cream), Anzac (a novelty in bluish-mauve and light maroon), and Jean Ireland were other excellent sorts.

Messrs. Alex Dickson and Sons, Newtownards, had many notable sorts in a most attractive exhibit. We thought The President (rich scarlet) the most notable sort, and certainly nothing in the Sweet Pea line was so brilliant. Orchid (mauve), King White, Fiery Cross, and Hawmark Cream are some others that appealed. A particularly attractive exhibit was that from Mr. J. Stevenson, Wimborne, who exhibited several novelties of his own raising. Stevenson's White, Warrior (maroon), Honour Bright, Victory (salmon-red), and Golden Glory (orange-scarlet) were among leading sorts. Messrs. Bide and Sons, Farnham, Messrs. Piper and Sons, Bayswater, and Robert Sydenham, Limited, Birmingham, also exhibited these flowers.

STOVE AND GREENHOUSE PLANTS.

Some magnificent groups of tender annuals and other greenhouse flowers were to be seen in this section. Two of the most notable were arranged at opposite ends of one of the great tents, and never have these popular, easily-grown subjects been more prodigally displayed. In the groups from

Messrs. Sutton and Sons, Reading, the main features appeared in great semi-circular banks formed chiefly of their superb strains of *Calceolaria*, *Gloxinia*, *Star Cinerarias*, *Phlox Drummondii*, and *Schizanthus*, among which latter *S. retusus Rosy Gem*, a good colour advance, claimed attention. *Nicotianas* in variety, peering out in groups from the main blocks of colour, broke up the formality of the whole, while *Primula obconica* gave a feast of colour in white, blue, mauve, rose, carmine, pink, and other shades difficult to describe. The fragrant blue-flowered *Exacum affine* came in for a fair share of attention. A Gold medal was deservedly awarded. Equally well merited was the Gold medal awarded to

Messrs. Carter and Co., Raynes Park, S.W., whose sumptuous colour groups for the most part appeared in bedded form as grown in the garden. For example, there were great oblong beds of pure white and earmine coloured Stocks, White Pearl and Crimson King respectively, circular beds of single and double Begonias, of diverse-coloured Petunias in perfection, and others all springing from a lawn of the finest Grasses. Beyond and behind were banks of Victoria Prize *Calceolaria*, of "Star" and large-flowered *Cinerarias*, superbly grown Clarkias, and *Schizanthus*. A background of noble and graceful Palms made the picture complete. Its conception and execution were alike admirable.

Messrs. Webb and Sons, Stourbridge, also showed well of the same classes of plants, *Calceolarias*, *Schizanthus*, Begonias, *Cineraria stellata*, and others of the large-flowered class appearing in semi-circular, conical-shaped banks from a groundwork of Ferns and Grass. *Amaryllis*, too, of an excellent strain, played an important part.

The Hon. Vicary Gibbs, Aldenham House, Elstree (gardener, Mr. E. Beckett), contributed a most interesting assortment of sweet-scented Pelargoniums in well-grown examples, both standard and bush grown being staged. Particularly interesting was the collection of insectivorous and allied plants from

Mr. A. P. Bruce, Chorlton-cum-Hardy, Manchester. We have seen them from the same source more finely coloured and developed than on the present occasion, though they are always attractive and represent high-class cultivation. Sir Frank Crisp, Farnham, *flava magnifica*, and Brucei were some good kinds in the first-named group, though many good specimens

of *S. purpurea* were remarked. Of the Sundews (*Drosera*), *D. muscipula erecta* was quite distinct.

Messrs. H. Cannell and Sons, Eynsford, Kent, had an exceptionally good exhibit of show and fancy Pelargoniums associated with *Calceolaria Clibrani* and other things. Messrs. Peed and Sons, West Norwood, showed a fine lot of *Caladiums*. Silver Queen, Triomphe de Comte, Alexander III., and the Mikado were some of the more conspicuous. *Hippeastrums* were admirably shown by Messrs. R. P. Ker and Son, Liverpool. Mr. Alfred Dawkins, King's Road, Chelsea, showed an excellent strain of *Schizanthus*, compact-habited plants rich in variety and large-flowered. Mr. L. R. Russell, Richmond, was the only exhibitor of choice specimen stove plants, the group rich in *Alocasias*, *Caladiums*, *Dracenas*, and other plants. A notable lot of *Nertera depressa* was remarked. Messrs. Blackmore and Langdon, Bath, had some very fine Begonias associated with a ground group of *Delphiniums*. Messrs. T. S. Ware, Feltham, staged their Begonias on a table, where they were seen to better advantage.

Messrs. H. B. May and Sons, Edmon-ton, were responsible for a group of *Hydrangeas*, *Marguerites*, *Pelargoniums*, *Heliotropes*, and other useful subjects, showing elsewhere a goodly collection of Ferns rich in the newer forms of *Nephrolepis*, and attractive by reason of the several kinds of *Platyterium*. Messrs. Thomas Rochford and Sons showed a group of the newer *Astilbes*, of which Princess Mary (Award of Merit), Peach Blossom, and America were the best.

FLOWERING TREES AND SHRUBS.

The number of hardy ornamental trees was not on so vast a scale at this meeting as usual. Lilaes and *Rhododendrons* have never been finer, and the groups of these, in conjunction with the Azaleas, provided a feast of flower-beauty at once worthy of British horticulture and the unique exhibition in which they played so good a part.

Messrs. Waterer, Sons, and Crisp, Bagshot, had a grand display of *Rhododendrons*, relying on a few sorts and employing these with a free hand. Their new Bagshot Ruby, which gained an Award of Merit, was, without doubt, the most brilliant variety in the show, both bush plants and standards demonstrating its value. Pink Pearl and Mrs. C. E. Stirling, giving a glorious truss of exquisite pink-blush flowers, were in great force and much admired. *Cynthia* (bright rosy-red) was also excellent.

Messrs. George Bunyard and Co., Maidstone, formed a background to an Iris group with *Rhododendrons* Alice, Pink Pearl, and *Cynthia*, Mrs. C. E. Stirling flanking either end. Here, too, were many Azaleas, mollis and sinensis, affording rich colour variety.

Messrs. R. and G. Cuthbert, Southgate, N., brought a magnificent lot of Azaleas, representative of *occidentalis*, *rustica*, mollis, and others. Of this last there was a superb display, though the exquisite tints pervading the group merited equal praise. Messrs. James Carter and Co., Raynes Park, associated Ghent and other Azaleas with *Rhododendron* Pink Pearl and others, Messrs. Piper using *Azalca amœna* with a free hand with Maples. Of Lilaes nothing finer, probably, has ever been staged than the superb collection brought by

Mr. R. C. Notcutt from Woodbridge, the wondrous flowering of the standard-grown examples impelling admiration. The double white varieties Jeanne d'Arc and

Miss Willmott were grand, yet equally good in their way the dark-coloured varieties as Reamur, Souvenir de L. Spath, Congo, and Charles Joly. Of lighter hue is President Grevy. Both Mr. Chas. Turner, Slough, and Messrs. Paul and Son, Cheshunt, showed excellent collections of the best of these indispensable flowering shrubs.

Mr. G. Reuthe, Keston, in addition to a great variety of Himalayan Rhododendrons, had a fine lot of the brilliant "Fire Bush" (*Embothrium coccineum*), only hardly in the more favoured parts of these islands. In the group from

Messrs. J. Cheal and Sons, Crawley, *Cytisus Dallimorei* was very beautiful, and not less so the charming *Leptospermum Nicholi*. In addition there were *Viburnums* and many well-flowered Ghent Azaleas.

Messrs. Fromow and Sons, Chiswick, displayed Japanese Maples in almost endless variation and diversity of form and colouring. Maples, too, predominated in a group from Mr. L. R. Russell, together with such things as *Ledum*, the ornamental Chinese Vines, *Ceanothus Veitchianus*, *Cytisus Dallimorei*, and the unique *Rosa Moyesi*.

Messrs. George Jackman and Son, Woking, staged a circular group of Clematis, the outstanding variety being *Crimson King*, which gained an Award of Merit. While "erimson" is, to some extent, a misnomer, the colour is, notwithstanding, of a rich vinous red shade, quite unique in its set. Mrs. George Jackman, Lady Northcliffe (pale mauve-blue), Nellie Moser, and Ville de Lyon were others of note.

ORCHIDS.

The Orchid groups arranged on two opposite sides of one of the great tents, if not of the same magnitude as in other years, were highly representative. The most noticeable gaps were due to the absence on war service of Lt.-Col. Sir George Holford and the death of Mr. Gurney Fowler, both staunch supporters in the amateur section.

Sir Jeremiah Colman, Bart., Gatton Park (gardener, Mr. Collier), was the only amateur exhibitor of an extensive collection; one, however, rich and replete of brilliantly-flowered *Odontiodas* and finely-blotched *Odontoglossums*. The former included the lovely *O. Colmani* (of rich yellow and red colour), *O. Bradshawæ* (Gatton variety), and *Lælio-Cattleya Golden Glory*. A special interest attached to the group, since most of the good things were raised by the exhibitor.

Messrs. Armstrong and Brown, Tunbridge Wells, had a group notable for the rich array of novelties, the comparatively small number of plants, and a style of arrangement which, while novel and displaying the plants to the best advantage, was simple in the extreme. Every plant stood out from a bed of Ferns, the background or screen, to a height of several feet, draped with the choicest examples. Rich in the fine blotched *Odontoglossums*, of which *O. crispum Lusitania* was one of the best, it was equally so in *Odontiodas*, *O. Seymouræ* and *O. Anzac* being remarked. The green and black *Cologyne pandurata*, *Miltonia J. G. Fowler*, *M. Frank Reader* (of rosy colouring with butterfly-like, maroon-coloured blotch) were some of the more important.

Messrs. Sander and Sons, St. Albans, had some lovely *Miltonias*, of which *M. Charlesworthi*, *M. Hyeana* variety *Sunrise*, and *M. vexillaria* *seintillans* were all remarkably fine. *Dendrobium Sanderae* (very rare white-flowered kind), *Odonto-*

glossum crispum-Harryanum, and *Cattleya Mossiæ Reineckiana*, and *Princess Olga* of Russia were others of conspicuous beauty. Prominent in the splendid group from

Messrs. J. and A. MacBean, Cooksbridge, was the new *Odontoglossum crispum Aldworthi*, of rich red colouring. It gained an Award of Merit and the Davidson eup for the best variety of *O. crispum*. The rare white-flowered *Dendrobium Sanderae*, the yellow *Oncidium MacBeanianum*, with *Cymbidiums* and the scarlet *Odontioda Vuylstekeæ* (MacBean's variety) were other notables.

Messrs. J. Cypher and Sons, Cheltenham, showed well of such good things as *Lælio-Cattleya Hyeana splendens*, *L.-C. Baden-Powell*, and *Lælia purpurata*. *Dendrobium Wardianum* was profusely flowered, while *Miltonias*, in variety, *Renanthera Inmschootiana*, and *Cattleya Mossiæ* and *C. Mendelli* were all good. Good things in

Messrs. Stuart Low and Co.'s group were *Lælio-Cattleya luminosa* variety *aurea*, *Odontioda Gladys*, *Cattleya Mossiæ grandis*, the white *Phalænopsis Rimestadiana*, and the scarlet *Renanthera Inmschootiana*.

Messrs. Charlesworth and Co., Haywards Heath, in a group of exceptional excellence had three of the new *Oreheids* gaining awards, these being *Brasso-Lælio-Cattleya Joan* var. *Verdun* (first-class certificate), best described as an all-yellow *Cattleya*, *Odontioda Florence* (rose and white), and *O. Drewi cuprea*, which, while unique in form and distinct from all other *Odontiodas*, is equally so in the tawny orange colour of its flowers. Sent by

Miss Louisa Fowler from the rich collection of the late Mr. J. Gurney Fowler, were a few choice things, notably *Odontoglossum ardentissimum Memoria J. Gurney Fowler* (white, with nearly heart-shaped maroon blotch), *O. Princess Mary*, *O. illustre Europa*, and the lovely *O. crispum Solum*, among others.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM MAY 25TH.—*Berberis* (in great variety), *Lilacs*, *Rock and Sun Roses* (in great variety), *Bush and Climbing Honeyuckles*, *May* (single and double), *American Thorns* (in variety), *Labrunums*, *Sweet Bay*, *Magnolias* (in variety), *Dierollas* (in various colours), shrubby *Spiræas*, *Pernettyas*, *Coronilla Emerus*, *C. glauca*, *Snowdrop-tree* (*Halesia tetraptera*), *hardy Heaths* (in variety), *Cornus florida*, *Cydonicus* (in various colours), *Pyrus Malus* (various), *Menziesias* (in variety), *Calycanthus macrophyllus*, *Grevillea rosmarinifolia*, *Staphylea colchica*, *Pearl-bush* (*Erochorda*) (various), *Rock Spray* (*Cotoneaster*) (several), *Notospartium Carmichaelia*, *Daphnes* (in variety), *Azaleas* (in great variety), *Rhododendrons* (in great variety), *Japanese Cherries* (various), *Rosa* (many species), *Ribes speciosum*, *Judas-tree* (*Cercis Siliquastrum*), *Photinia villosa*, *Rocky Mountain Bramble* (*Rubus deliciosus*), *Potato-tree* (*Solanum crispum*) and its *Glasnevin* variety, *Fendlera rupicola*, *Lonicera pileata*, *Deutzias* (*Lemoine's* hybrids in various colours), *Rubus flagelliformis*, *Andromedas* (various), *Kalmias* (in variety), *Pyracantha*, *Lelandi*, *Cytisus monspesulanus*, *Cornus alba*, *Patridge Berry* (*Gaultheria*), *Red Chestnut* *Rubus nutkanus*, *Herbaceous and Tree Prunics* (various), *Anchusas* (in variety), *Antennaria tomentosa*, *A. dioica*, *rosæ*, *Wood Lilies* (*Trillium*), *Iceland and Oriental Poppies*, *Lupins* (in variety), *Mule Pinks*, *Maiden Pinks*, *Alliums* (various), *Columbines*, *Camassias* (in various shades), *Primulas*, *Polyanthuses*, *Erinus alpinus* (in white, rose, and purple), *Alpine Phlox* (in variety), *Scilla italica*, *Cheiranthus linifolius*, *C. alpinus*, *Scilla muralis*, *C. glomerata dahurica*, *Wahlenbergia serpyllifolia*, *Houstonia corulea*, *Ranunculus speciosus fl.-pl.*, *Achillea serbica*, *A. rupestris*, *A. Woodall's variety*, *Thymes* (various), *Candytuft*, *Monroe's Mallow*, *Pentstemon Scouleri*, *Ethionema* (in variety), *A. grandiflorum*, *Linaria pallida*, *Linum alpinum*, *Helianthemum alpestre*, *Isolirion tataricum*, *Oxalis* (in variety), *Globe flowers* (various), *Kinacups* (various), *Poet's Narcissus* (single and double), *Geums* (in several varieties), *Silene sylvestris*, *Violas* (in variety), *Potentilla argrophylla*, *Reseda*

glauca, *Eremurus himalaicus*, *E. robustus*, *Meconopsis cambrica*, *M. sinuata latifolia*, *Heucheras*, *Virginian Cowslip* (*Mertensia virginica*), *Asphodelus luteus*, *German Iris* (in several varieties), *Tufted Pansies* (in great variety), *Tree Lupins*, *Cornus canadensis*, *Scilla hispanica*, *Transvaal Daisy* (*Gerbera*), *Canary Creeper*, *Gazania splendens*, *Anemone sylvestris*, *A. palmata*, *Libertia formosa*, *Rodgersia palmata*, *Rheum palmatum*, *Ranunculus Lingua*, *Day Lilies*, *Sedum spathulifolium*, *Everlasting Peas*.

WORK OF THE WEEK.—Summer-leaving Ferns are now growing freely. Decaying fronds, etc., have been removed to show the delicate and rapidly-developing new fronds to the best advantage. A few Hart's-tongue and Maiden-hair *Spleenwort* Ferns have been planted at the base of a shady wall, where established plants were seen to be happy. Hardy *Chrysanthemums* have been cleaned and the surface-soil freshened up among the plants. Herbaceous *Phloxes* have been treated similarly. German *Irises* are now flowering freely below tall deciduous trees and shrubs. *Wood Lilies* (*Trilliums*) are extremely beautiful this year. In half-shade these lovely flowers are seen to great advantage. Plants raised from seed have been pricked out into nursery beds, which have been given a good layer of fine light soil, as this enables the seedlings to quickly establish themselves. *Polyanthuses*, *Carnations*, *Campanulas*, *Aconitum vulgibile*, etc., have been so treated, and a few plants, struck from cuttings inserted last autumn, of *Desfontainia spinosa* have now been put out on a warm border. A plant of *Lonicera Alberti* has been added to the shrubbery. Several vases in the flower garden have been made up with *Cannas*, the little *Sand Verbena* (*Abronia umbellata*), and *Shamrock Pea* being planted near the edge to drape them. Other large vases containing *Lilies*, *Sedums*, *Hydrangeas*, *Sweet Verbena*, etc., have been taken to their summer positions, and various others will be added as they become sufficiently hardened. The hoe is kept going whenever possible on fine days. Dead flowers are kept removed. Such things as *Rhododendrons* may have their seed-vessels taken off in order to throw vigour into the plants. A few more seeds, such as *Mignonette*, *Phacelia*, *Cosmos*, and other dwarf annuals have been sown.

Clematises are making rapid strides, and a little training is necessary where they are growing on fences, pergolas, and tripods, as, if tying in is neglected, the young growths become entangled to such an extent that it is almost impossible to separate them. Further progress has been made with the mixed border, and *Larkspurs*, which are breaking very strong this year, have been supported with *Hazel boughs*. A large bed has been planted with *Fuchsias* in various sizes. Another bed has been planted with *Cannas King Humbert* and *Alphonse Bouvier*. E. M.

Sussex.

SOUTHERN COUNTIES.

Second-early *Peach-house*.—The trying ordeal of stoning having been safely passed, and the number of the fruits having been reduced to safe limits on each tree, the fruits must now be exposed as far as it is possible to do so to the full influence of sunlight. Tying down having been somewhat neglected of late, this has now had attention. In the performance of this, any shoot likely to unduly shade a fruit is tied on one side. Lateral growths are pinched back and the points taken out of all shoots which have reached to and have grown somewhat beyond the limits of the trellis. A good soaking of water applied after giving a final dressing of fruit-manure puts matters right in this direction as far as the roots are concerned—at any rate, for a time. Vigilance must not be relaxed, and further supplies of water be supplied directly it is found necessary. Although a further dressing of artificial manure is not admissible, the application of liquid manure is by no means precluded, and may be employed up to the time the fruits begin to change colour. Syringing for some time to come must be assiduously attended to. This should not be carried out in a perfunctory manner or by just merely damping the foliage, but every leaf should be thoroughly wetted, and then neither aphid nor red-spider will give any trouble.

Melons.—The fruits being now about to change colour, further supplies of stimulants must be withheld, applying clear water only, the supply being so regulated that the roots receive just enough to prevent the leaves flagging. This, combined with a free circulation of warm, dry air, obtained by a judicious use of both top and front ventilators, will ensure good finish and flavour of high quality. When the stalks begin to crack at their base and the Melons to emit a powerful aroma, the fruits are then in fit condition for cutting and taking to the fruit-room, where in the course of a few days they finish properly, and are then in a satisfactory condition for sending to table.

Successional crops.—Plants on which the fruits are swelling now need to be well fed at the roots and to have all lateral growths—provided the premier leaves are intact—pinched out as fast as they appear, which concentrates the energies of the plants on the production of fruit alone. Careful and regular syringing with tepid water keeps the foliage in a clean and healthy condition,

while frequent damping of the paths and bed surfaces maintains the requisite degree of humidity while the ventilators are open for the due admission of air.

Fruit swelling off on later plants must be assisted with ample supplies of tepid water to the roots, and in affording stimulants by these means twice or thrice a week. Further additions of loam fortified with bone-meal are also necessary, this being placed on the margins of the mounds and made quite firm. The fruits, as soon as they are of any size, must be given the support of nets, which, if properly adjusted, allow for full and proper development without the fruits coming into contact with the trellis. If any part of the trellis is bare, a few laterals may be trained out and then stopped to cover the same, otherwise close pinching or repression of such growths is the best means of ensuring fine, handsome fruits.

Protection.—Both coping-boards and nets may now be finally removed from fruit walls, as neither will be further required this season. This should be followed by a light loosening of the surface of the alley, which becomes very firm as a result of passing so frequently up and down it when attending to the trees. Mulching this season will have to be omitted, but a sprinkling of artificial manure given previous to the loosening of the soil does not take long to apply, and proves beneficial.

Raspberries.—These are already sending up an abundance of young growths, which if left will soon convert the plantation into a veritable thicket if not thinned out, and that without delay. This thinning is done so that, beyond making an allowance for accidents and so on, no more young canes than are required for the future furnishing of the trellis are retained. The surplus is hoed off at ground level and raked off. This proves beneficial not only as regards the new and growing canes, but it also ensures a full share of light and air being experienced by the fruiting canes as well as enhancing both the quantity and quality of the produce.

Forced Strawberries.—Plants forced in the early months of the year can be planted without further delay. A good soaking of water should be given previous to and after planting. These plants will give a full and profitable crop another season, and should the autumn prove fine and warm a sprinkling of fruit may be looked for then in addition.

Planting out.—This, having been curtailed as much as possible, is being pushed on, and will be brought to a conclusion as speedily as possible. All subjects are carefully watered prior to planting, and another good watering given on its completion. Got out on these lines, the plants, however hot and dry the weather may prove afterwards, are safe at least a week or ten days before water is again required. Where the material is at command, and time and labour will allow, the present season will offer a good opportunity for demonstrating the value of a surface mulch of spent Mushroom dung, leaf-mould, or anything that will arrest a too-rapid evaporation of moisture. A. W.

MIDLAND COUNTIES.

Melons.—The earliest house of Melons having been cleared of fruit, another batch of young plants is ready for replanting it. A part of the old soil is removed from the bed and fresh loam added and made up as described in previous notes. The house has been thoroughly cleaned down. The plants require a little shade in the middle of the day until well established. In houses where the fruits are colouring, the supply of water at the roots is reduced, but not sufficiently to cause the plants to flag. Plants now swelling their fruits are afforded liberal supplies of liquid-manure, but feeding is discontinued directly the fruits show signs of colouring. During hot, sunny weather Melons need extra attention in regard to watering and feeding. If they once suffer from drought a check is caused and the fruits are apt to split. The atmospheric temperature at night should range from 70 degs. to 75 degs., and the house should be closed early in the afternoon in order to utilise the sun heat, so that the temperature may rise to 95 degs. The plants should be examined once or twice a week, and any lateral growths removed before it is necessary to cut a large quantity away at one time, this invariably causing a check to the plants. Pinch the laterals generally to one leaf beyond the fruit, but where there is sufficient room on the trellis the laterals may be allowed a little more extension than those on the lower part of the plant. This will encourage a flow of sap to the fruits and tend to increase root-action.

Cherries have set remarkably well and the crop will be abundant provided the fruits are not unduly thinned during the stoning period, this not infrequently happening from want of water at the roots. Now that the fruit is set the shoots may be safely thinned; at the same time provision must be made for next year's crop by leaving a sufficient supply of the best-placed shoots for the purpose, or, if the spur system of training is adopted, stop the most suitable growths beyond the third or fourth leaf. Keep a diligeat watch for black aphid, and once it is observed either thoroughly syringe the trees with Quassia extract or dip the affected shoots.

Plums are a much lighter crop, and the fruits will not require any thinning. Dis-

budding of all trees should be brought to a close, and from this time onwards attention must be given at intervals to summer-pruning.

Pears on walls are the first to claim attention. The breastwood should be shortened and sufficient young wood trained in to furnish the space. Cordon Pears also require close stopping to keep them in a fruitful condition. Pyramids and bushes may be pinched and thinned to a reasonable degree, and the work must be regulated by the space available for them. The shape of bush and pyramid trees is a matter of great importance. The side shoots of pyramids should be pinched early to about five leaves, and the subsequent shoots pinched once or twice, according to the season, to within two leaves of the first pinching. Leading shoots are thus encouraged to grow strong, and by this method the whole tree becomes fertile. Standard trees, when once established need no restriction of the shoots, and they soon become fruitful.

Celery.—The planting of Celery is continued as the plants become ready, choosing showery weather if possible. If these conditions are not available, only a few plants are lifted as required, giving them a good soaking with water immediately after they are planted. Damp the foliage each evening and sprinkle it freely with soot, which is an excellent preventive of the Celery-fly.

Autumn vegetables will now be planted in quantity as opportunity occurs. Autumn Cauliflowers are most useful, but need liberal treatment, such as a good root-run and an ample supply of moisture in dry weather. Few plants pay better for deep cultivation, and to secure a full season's growth the plants should be got out as soon as possible. Much the same advice applies to the early autumn Broccolis, such as Self-protecting, Michaelmas White, and Walcheren. In our case these will be planted on ground where winter Spinach has been dug in. The latest planting of Brussels Sprouts will be made at once. Leeks are also ready to be put into their permanent quarters. For September and October supplies a small sowing of the Rosette Colewort will be made now, sowing thinly to secure good plants. Another sowing will be made about the end of the month, and the last the second week in July.

Parsley will be sown again for use in autumn and early winter. For mid-winter supplies it will suffice to make a sowing in a couple of months. Encourage a free growth in the plants from the early sowing by loosening the surface-soil frequently. Occasional dustings of soot not only stimulate growth, but also prevent slugs eating the plants, and impart that dark green colour so much admired in this herb.

Onions.—Beds of transplanted Onions intended for producing large bulbs will, in the absence of rains, need damping each evening, soaking the plants at the roots occasionally with clear water to induce a free growth. When moisture is applied to the soil during hot weather the surface of the ground becomes caked, therefore use the Dutch hoe frequently between the rows. Any failures in the rows should be made good without delay, and a sharp look out kept for the Onion mildew. If any signs are detected dust the plants freely with black sulphur. When the plants are growing freely it will be a great benefit to mulch the rows with horse-droppings, such as are used for Mushroom beds. Autumn-sown Onions that were planted out early in the spring are bulbing freely, and are afforded plenty of stimulants. F. W. GALLOP.

SCOTLAND.

Hardy annuals.—Encouraged by the dripping weather, annuals of all kinds have made satisfactory progress, and some further thinning was done during the week. As is always the case when the soil continues damp for some time, slugs are more than usually numerous, so that in thinning some allowance is made for possible damage by these minute pests. To check their activities as far as possible, free dustings of soot are employed. These to be effective must be renewed at short intervals until the soil again dries up.

Beds of Tulips.—During the week beds of Tulips, chiefly grown for cutting, were cleaned and hoed over. These are chiefly May-flowering varieties. One of the most popular is Clara Butt, which is not only useful for cutting, but is decidedly showy when grown thickly in a bed. *T. retroflexa* is very graceful, but hardly so valuable for cutting, its somewhat slim stems occasionally bending over. *T. Gesneriana*, with its vivid crimson blooms, each with a blue-black base, is very stately and handsome. *T. fulgens*, a good ruby-red Tulip, shows up well under artificial light, and in conjunction with Lilies of the Valley, makes an effective table decoration. The showy and curious Parrot Tulips are, perhaps, hardly so popular as the varieties above mentioned, but when used in wide glass bowls with a mixture of Solomon's Seal they attract attention in rooms. If possible, during the present season the bulbs will be permitted to occupy the beds for a longer time after flowering than is usually allowed. There is a likelihood that the importation of bulbs may be curtailed, if not altogether prohibited, so that more than usual dependence must be placed on bulbs which have already done service. If fairly well ripened off before being lifted, and trans-

ferred to a shady spot to mature their growth, there seems to be no reason why such bulbs need be much inferior during next spring. Probably the blooms will not be so large, but they will be sufficiently so for ordinary purposes. In addition, the prohibition of importation may induce many to give a trial to home-grown Tulip bulbs—unless, indeed, the prohibition extends to Ireland, from which country I have had Tulips equal, if not superior, to the best importations from the Netherlands.

Irises in frames.—These, planted out in beds in cold-frames, as has previously been indicated, are grown in considerable quantities for cutting. Growth now has necessitated the removal of the sashes, and from time to time liquid manure is given to assist the plants. The Spanish Irises come in at a useful time when grown in this way, and succeed the latest Tulips. When their season is over the English Irises are beginning to be available, followed by those of both varieties in the borders. It will thus be seen that the season of these useful Irises is prolonged over a considerable period. If cut when the first bloom of the spike is developing, the flowers pack well, endure a long railway journey well, and last well. Sufficient quantities of their own foliage are sent to mix with the blooms.

Dahlias.—A finish was made in the course of the week with the planting of Dahlias. These plants were those raised from a limited (during this year) number of favourite varieties for massing. Among those varieties is the old Glare of the Garden, always largely used. Its small, vivid-scarlet blooms, and its moderate habit of growth make Glare of the Garden useful for beds or for colonies in borders. A very few of the Cactus type were similarly used, preference being given to those which carry their blooms erect, instead of, as is the case with some excellent Cactus Dahlias, having drooping heads. The majority of Dahlias, however, were planted some time ago in a dormant state, and are now showing signs of growth.

Ferns under glass are making considerable progress. Shade is now essential, and as the pots are rapidly being filled with roots, copious supplies of water are necessary. These are at present very effective, the varying shades of green among the young fronds being noteworthy. Pterises may shortly go to cold-frames for the summer. If possible, a frame with a northerly exposure should be utilised for the summer quarters of these accommodating Ferns.

Cosmos.—A good quantity of Cosmos was got out under excellent conditions during the week. The white variety is, perhaps, hardly so effective as those of a purple or pink shade; nevertheless, in some parts of the garden they are freely used. The blooms are not without value for cutting, and require no other green than their own light and graceful foliage.

Hardy fruit.—A little tentative thinning has been done on Peach and Nectarine trees, which have set very freely. This work will be continued at intervals until all the trees have been gone over; but, as there is always some risk of fruit dropping at stoning-time, the final thinning will be delayed until that critical period is over. In the case of Nectarines there is some trouble at times from leaf-curl or blister. It is now generally conceded that this proceeds from sudden changes of temperature, and that being so it is not to be expected that any particular wash will prove quite effective. Dusting with flowers of sulphur at times is not without value, and, differing from some other growers, I prefer to dispense with syringing the trees with specifics of any kind until the weather becomes more genial. A tree syringed in the late afternoon cannot possibly have dry foliage before nightfall, and wet leaves are, I feel certain, an incentive to blister. With milder weather this soon passes away, and any blistered leaves should be regularly removed and burned. Peaches in these gardens are not affected by blister. Pears are setting freely, and the crop will, from present appearances, be of quite average size. Marie Louise, Souvenir de Congres, and Winter Nelis on a wall with a south-easterly exposure are at present in bloom, and promise well. Plums, including Braly's Gage, Oullin's Golden Gage, Pond's Seedling, Kirke's, Reine Claude de Bavay, Jefferson, Golden Transparent Gage, and Washington, on a west wall, give indications of a heavy crop. Those on a south wall are further advanced, and, as was the case last year, trees of the old Green Gage will yield excellent returns. It is a pity that the small size of this Gage has made it unpopular among present-day planters, for, beyond doubt, it is of far superior flavour to most of the newer and larger-fruited Gages.

Plant-houses.—Watering is rather a prolonged business now when the weather is bright, and it will be found that many plants need looking over both morning and night. It will be noticed, too, that plants dry up much more quickly in some houses than in others. At the same time, close observers will agree that the best-grown plants are not necessarily those which furnish the best display of bloom. Shading is now necessary. Damp down the floors occasionally on sunny days, and a chink of ventilation may be safely left at the apex of the houses over night. Liquid manure may now be used freely, giving a change of stimulant from time to time. In the stove let the fire go out in the morning, and kindle it late in the afternoon. It is better for the plants than keeping them, as it were, between two fires—hot pipes below and sun

heat above. Syringe freely morning and night. Eucharis Lilies may now be potted on; and if any old plants require to be broken up, now is the time to do it. Night temperature, with but little fire heat, may be easily maintained from 65 degs. to 70 degs., according to the heat required by the class of plants grown. W. McGuffog.

Balmoe Gardens, Kirkcudbright.

OBITUARY.

MR. GEO. WYTHES.

WE regret to announce the death, at the age of sixty-five, of Mr. Geo. Wythes, who passed away on May 25th at Folkestone, where he was living in retirement. He was born at Worcester in 1851. At a very early age he was left an orphan, the youngest of ten sons, and was obliged to go out into the world to earn his living at the age of twelve. Not being very robust, he chose the open-air life of the gardener, a start being made at Whitborne Hall, Hereford, where at that time there was a fine collection of trees and shrubs. After moving about to various gardens in the quest for knowledge, he went to Dickson's Nurseries, Chester, where he was offered, and accepted, the situation of general foreman of the Alexandra Public Park, Manchester. After leaving Manchester, he was appointed head gardener at Thirlestone Hall, near Cheltenham, where he specialised in the culture of vegetables. Here he discovered the Cheltenham Green Top Beet, which at that time was being grown in a local nursery. Recognising the distinctness of this Beet, he procured some seed, and by continual and careful selection obtained a certificate for it from the Fruit Committee of the Royal Horticultural Society. At Thirlestone, specimen stove and greenhouse plants and Orchids were largely grown. In the culture of these, Mr. Wythes was very successful, and many were the prizes he won for them in the neighbourhood. On leaving Thirlestone, he took charge of the gardens at Teddesley Park, belonging to Lord Hatherton. In 1887, on the death of Mr. Woodbridge, at Syon House, he was appointed his successor. Here he remained until, owing to ill health, he was obliged to retire in 1906. During the time he was at Syon House he was a frequent exhibitor of fruit and vegetables at the shows held in London. Here, too, he raised some good Potatoes, including Syon House Prolific and others. He also turned his attention to French Beans, Progress being one of the best varieties he raised. Of Melons, too, he also gave us some good sorts. He was among the first, if not the first, to advocate the culture of Strawberries as annuals, and the result of this mode of cultivation was seen in the handsome fruits he grew. Mr. Wythes was a member for many years of the Fruit Committee of the Royal Horticultural Society. He also took a great interest in the Gardeners' Royal Benevolent Institution, of the committee of which he had for many years been a very active member.

He was one of the body of leading gardeners to whom the Victoria Medal of Honour in Horticulture was granted at its institution.

"**Daffodil Year Book.**"—In view of the very great increase in the expense of paper and printing, and of the labour difficulties attending it, the Council of the Royal Horticultural Society have resolved to suspend the publication of this year's "Daffodil Year Book." In coming to this resolution they are not wholly uninfluenced by the fact that the "Year Book" has never paid even half its cost, and last year, 1915, the sales of it only amounted to one-ninth of its cost.—W. WILKS, Secretary.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.

Naming plants.—All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.

Naming fruit.—Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.

PLANTS AND FLOWERS.

Epiphyllum truncatum (S.)—This can be propagated very readily from cuttings. Handsome plants may be produced by grafting on the Pereskia—a plant with a woody stem. The operation of grafting is very simple. Cut a diagonal notch in the stem of the stock, place in it the point of the Epiphyllum growth, broken off at a joint; it must then be fixed in its place with a small wooden peg.

Plants for dry ledge (Cornwall).—The following should do well in the position you refer to.—Zauschneria californica, Snapdragons, Campanula muralis, Sedum Sieboldi, Thymus lanuginosus, Alyssum saxatile, Dianthus deltoides, Linaria Cymbalaria, Helichrysum bellidioides, Saponaria ocyroides, Arenaria montana. Any of the Sedums or Sempervivums should be happy in such a position.

Vallota purpurea not flowering (R. M. C.)—This plant is easily flowered if the following points are attended to:—In the first place, it should be remembered that it is an evergreen bulb, requiring only just enough water in winter to keep the foliage green, and then, again, like all other hibernous-rooted plants, the pots should be full of roots at flowering time. When starting into growth, place them in a light position, watering carefully during the spring, increasing the amount of water as the season progresses, giving plenty of air all through the summer, and but little shade. It may be that in your case the roots are unhealthy, and we would advise you to examine them. If they are so, shake away the old soil, and repot into a pot just large enough to contain the roots.

Lily of the Valley not flowering (Canterbury)—As your bed is evidently an old one, the roots have doubtless become crowded, and an impoverished condition generally has resulted. Select a fresh position, where fresh soil would be at hand. If this cannot be done, give an entire change of soil, taking out fully 15 inches of the old, and replacing by a like quantity from another part of the garden. Dig in plenty of old manure and leaf-soil, if possible. Some care will be required in digging out the old bed. Your best plan will be to cut the roots out in tufts 6 inches or 9 inches square, unless you can fork under them and lift them out bodily. Assuming you lift the beds in tufts, the latter should be again divided into pieces 3 inches square or thereabouts, preserving the runners as much as possible. The rows should be at least 9 inches asunder, and the tufts about 6 inches. It will be best to prepare the entire bed before replanting. In setting out the individual plants, keep the crowns well below the surface, and, above all, plant firmly. The autumn is the best time to remake the bed.

Treatment of plants after flowering (Amateur)—As a rule, our plants are very badly treated immediately they have given their chief show of beauty. This is a sad mistake, for none of our plants can give a satisfactory display the following season if neglected as soon as they have gone out of flower. To place a Camellia, Erica, Azalea, or any of the many useful greenhouse plants upon one side because its beauty is past cannot fail to bring future disappointment. Where so many are in standing such plants outside too early. Treat plants kindly for a time after the severe strain experienced dur-

ing flowering. How often do we see our hardy flowering plants and shrubs, such as the Spiraeas, Deutzia gracilis, Clematisses, Roses, and others, ruthlessly turned into the open at a time when they are fully three months in advance of outdoor growth. Yet their owners unreasonably complain of future failures, never having given the common-sense side of the question a thought. If the plants must come out of the house, let them at least have some slight protection for a time until cold weather is past. Roses, Deutzias, Azaleas, Camellias—in fact, almost all flowering plants—make considerable growth after flowering, much of which is already far advanced before the blossom is over, and, seeing it is on this after-growth that we rely for next season's blossom, it is surprising how many do not recognise the absolute need of protecting and maturing the same, instead of doing their utmost to ruin it.

FRUIT.

Vine leaves scalded (F. M. G.)—Judging by the leaves you send we should say that the trouble is due to scalding, through the ventilation not being properly attended to. Moisture settles upon the foliage at night, and if this is not dissipated early on bright and sunny mornings by ventilation carefully applied, or before the sun raises the temperature, scalding is sure to follow. You might try shading the particular Vine which is affected.

VEGETABLES.

Cucumber growing (C.)—The best way to do this is to make up a hotbed of equal parts stable-manure and leaves. When the violent heat has partly subsided, put a hill of rich soil in the centre of each light. One part of decayed manure to three parts of garden mould will do well. Put the plants out when the soil is sufficiently warmed. In three or four weeks they will have made considerable growth, and the whole surface of the bed should be covered about 6 inches deep with compost similar to that used for planting in.

Butter Beans (F. M. G.)—In France these are known as Haricot Beurre, some of them being of nearly the same colour as butter. The best varieties are Mont d'Or (a runner), Dugoin (a dwarf), Saint Piere (a runner), and Bon Jardinier (a dwarf), under which names seed can be had. The usual treatment given to Kidney Beans, as regards season, will do for the Butter Bean; but in this country it is always advisable to give it a warm corner and good, rich soil. The cooking is simple, and the way common with us of allowing Beans of all kinds to get too old will not hurt the Butter Bean so much, though no doubt it has its season of best condition like other things. The Pea you refer to is the dried seeds of our ordinary English Marrow Peas.

SHORT REPLIES.

Sydenham.—1, We have never heard of the Radish leaves being used in salads. 2, The unblanched parts of Celery may be used for flavouring soups.—E. C.—Try cutting it in the evening and soaking in water during the night, using it the following day.—W. W.—The corns have been kept too dry. It would have been better to have started them in small boxes and Cocoa-fibre, then, when they were growing freely, to pot them. The fact of the leaves being attacked by thrips shows plainly that they have been kept too dry.

NAMES OF PLANTS AND FRUITS.

Names of plants.—L. E. W.—1, Veronica Hulkeana; 2, Spiraea flagelliformis.—Mrs. S. Pain.—1, Billbergia species, cannot name from flower-spike alone, there being so many species in cultivation; 2, Coronilla Emerus.—A. Vigar.—1, Saxifraga muscoides atropurpurea; 2, Crassula tetragona; 3, Sedum Sieboldi; 4, Sempervivum arboreum probably, but cannot name from a leaf alone.—D.—1, Saxifraga ceratophylla; 2, Veronica vernicosa.—W. D. Halifax.—1, Saxifraga crustata; 2, S. Aizoon rosularis (probably); 3, S. Hosti (poor form); 4, S. Aizoon minor (probably), should be sent in flower; certainly not S. Engleri.—C. E. E. S.—Lonicera sp., impossible to say which, as flowers were faded.

CATALOGUES RECEIVED.

WM. WATSON AND SONS, LIMITED, Clontarf Nurseries, Dublin.—*Summer Bedding Plants.*

Book received.—"Flower Culture Month by Month," by Mary Hampden. Herbert Jenkins, Limited, Arundel Place, Haymarket, London, S.W.

Daffodil diseases.—Growers of Narcissi have suffered during the last few years from the loss of a considerable number of bulbs owing to the attack of a disease which has so far proved impossible of cure. The Royal Horticultural Society has just appointed an investigator to study the disease and, if possible, to devise means of checking it, and the Director of the Royal Horticultural Society's Gardens, Wisley, Surrey, would be glad if any having the disease in the foliage or bulbs of their Narcissi would send specimens to him with as full particulars as possible.

THE ELM A DANGER.

As to Mr. Ballard's letter in GARDENING ILLUSTRATED, what I meant was that the Elm should not be planted anywhere near a house, or a garden, or a drive. Anybody who wants Elms for timber should grow them in the wood, where there would be no danger. As Elms are planted in Britain they are a constant danger, and an average of a death a week is the result of their stupid planting. They have no root-system at all. The common Field Elm, so frequent in our counties, is not a British tree and is always multiplied from suckers, which may be a reason for its tumbling over from want of deep roots. Our native Elm, the Wych Elm, is a better-rooted tree and is easily raised from seed.

As to the Elm being a better-looking tree than the Oak, Beech, Ash, or Eastern Plane, that is a very odd statement. It is quite inferior in beauty to any of those trees. I have seen in Worcestershire a Pear-tree 60 feet high that I should think more beautiful than any Elm. The counties of Westmoreland and Hereford have many examples of our native trees much more beautiful than any Elm, and, as we now know, less liable to be blown over. The common Elm before these strenuous days had hardly any value as timber—one could hardly get 4d. a foot for it.

Mr. Ballard says that Yew, Holly, or Evergreen Oaks are less beautiful than the Elm. I should say it is quite inferior to any of those trees for beauty. The Holly is the most beautiful evergreen of the northern world, and in the past winter has been clothed in splendid colour of fruit. Our native evergreens, Yew, Holly, and Fir, should never be left out of any right planting. Any one of them, old and right as to place, is worth all the Elms known, especially for winter scene.

Mr. Sargent, author of the *Sylva of America*, and who knows all the trees of the greatest northern tree land, told me of his great delight in seeing old trees of our native Scotch Fir. And a fine old Yew may be called our native Cedar, and beautiful throughout the year, most so in winter storms.

W.

NOTES OF THE WEEK.

Primula Red Hugh.—We send you some blooms of this, the finest of the progeny of the Cockburniana and pulverulenta crosses.—J. STORMONTH & SON, *Kirkbride, Carlisle.*

[Very rich in colour.—ED.]

Mimulus Whitecroft Scarlet.—From Mr. Stormonth, of Kirkbride, we have a brilliantly-coloured Mimulus, Whitecroft Scarlet. It seems worth growing. These flowers have in my soil a way of leaving without notice. They may want frequent division.—W.

A brilliant Pæony (*Pæonia officinalis lobata*).—Mr. F. Gifford, of the Montague Nursery, Hornchurch, sends us a striking bouquet of this splendid scarlet Pæony, the fine colour-effect of which it is impossible to over-praise. He has grown it for many years, and we may be assured of its merit and hardness.

Aubrieta Beauté de Bade.—We enclose blooms of the Aubrieta Beauté de Bade. It is a little darker than Moerheimi, but its main qualities are its hardy, dwarf, dense habit. In these respects it excels any of the red shades we have tried, and we have bought all that we have seen offered.—J. STORMONTH & SON, *Kirkbride, Carlisle.*

[Very distinct in colour.—ED.]

Rhododendron Doncaster.—This brilliantly crimson-flowered variety arrests attention whenever seen. With me some plants, though small, are smothered with blooms of the most gorgeous colour. The brightly-coloured forms are somewhat liable to scorching, and this one, like many others, is not immune from this, but it is, nevertheless, an indispensable variety.—E. M.

Pink Gloriosa.—This is a great favourite of mine and the earliest of all to flower. It forms a dwarf, tufted plant of slow growth. The comparatively large double flowers are of a delightful shade of pale pinkish lilac, and very sweet-scented. I have had my plant for three years, and it has not increased greatly in size since that time. With its air of refinement it seems more suitable for a position in the rock garden than in the foreground of the herbaceous border.—K. R. W.

The Norway Spruce.—Mr. A. D. Richardson, writing in *Gardeners' Chronicle*, dissents from Sir Herbert Maxwell and

Mr. Elwes, who both say this tree is over-praised and over-planted. He is quite wrong, and cannot have observed what a poor tree it is over a large area in the southern counties. It misses the rain and long-melting snows on its native mountains, though it grows well in wet and northern districts and beside streams, but many places do not enjoy these aids.—W.

The phenomenal Loganberry.—Mr. W. Allan, The Gardens, Gunton Park, Norwich, sends us some heavily-fruited shoots of this, the individual fruits large and well coloured. As to their culture Mr. Allan says:—

"Grown in house with Figs, no foreing; come on with the season. Just now the berries are quite a beautiful sight, and if allowed to hang to get thoroughly ripe they are much liked."

A noble white Pæony.—Mr. Gifford sends us from the Montague Nursery, Hornchurch, a bunch of this very strikingly beautiful Pæony. The flowers are a fine white with great golden-yellow stamens, and the plant is covered with buds and flowers. The Pæonies of the herbaceous kinds are more amenable to our garden culture than the tree Pæonies and do not often get the place they deserve in our gardens. It is named by Mr. Gifford *P. albiflora grandiflora*.

Menzies' Arbutus.—Professor Jepson writes from the University of California:—"Our Arbutus Menziesi is, in my opinion, the most wondrously beautiful of all our Californian trees. It occurs mixed with other species, and very rarely have I found even a small grove of it keeping completely to its own kind. It is a great pleasure to know your interest in it and your plans for planting. I can send you this fall a quantity of the berries. The seed is rather easily germinated in nursery beds with us. If you prefer nursery stock, it can be supplied. I am asking the California Nursery Company at Niles to send you their catalogue."

The Dittany of Crete (*Origanum Dictamnus*).—J. Cornhill speaks of this on page 275 as being at one time grown as a window plant by cottagers. This reminds me that some years ago, when spending a holiday in a little old-fashioned village in Surrey, I found this plant in almost all the cottage windows. It was known by everyone there as Pink Hops, which name suited it well, as the clusters of blossom were in shape just like Hops in maturity.

This pretty flowering plant is permanently fixed in my mind, for in those days I was rather proud of my knowledge of plants, but had to confess my ignorance of its correct name.—K. R. W.

The war and the garden.—Many eligible men who had obtained postponements until the end of May have now joined the army, and the scarcity of garden labour has been intensified. Nor is this all, for men, who might otherwise have been available, can earn much higher wages at other work, and refuse to do garden work at all except for wages which some gardeners of experience would be only too happy to get. Under-gardeners of any experience cannot, at present, be got, and those who have still some of the old school of garden labourers ought to congratulate themselves, and, if possible, see that they are adequately remunerated in this time of high prices.—Kirk.

The Nootka Sound Bramble (*Rubus nutkanus*).—For naturalising in the wilder parts of the garden, along the banks of hedgerows, or at the foot of trees, where the shade is not too dense, this is an admirable plant. It grows about a yard high and bears in May and June handsome Vine-like leaves and pure white flowers, each from 2 inches to 3 inches across and set off by a central bunch of sulphur-coloured stamens. The plant spreads freely by underground suckers and soon forms small colonies if left to itself. Although it appears to be quite happy on the driest banks and beneath trees, the foliage and flowers are larger if the plants are given a moist position.—E. M.

London Pride for hopeless banks.—I send you a photograph of a bank of London Pride planted last July. I had a number of banks of inferior turf, requiring much labour to keep them in order, and never looking well. Last July I pared off all the turf and planted them with pieces of London Pride about 6 inches apart. These banks are now a mass of bloom, and, when the plants are out of blossom, are green and tidy, requiring no attention.—LEONORA L. YORKE SMITH.

[No doubt it is a useful plant for places where few other things will thrive—as good for wet and sunless places as dry ones.—ED.]

New Lilacs.—At the Chelsea Show Awards of Merit were given to two Lilacs, both of which were raised and distributed by M. Lemoine, of Nancy. The variety Réaumur has massive trusses of dark carmine-coloured single blossoms, while in the other, President Fallières, the double flowers are of a soft lilac tint. Much has been written of the evil results of grafting the choicer varieties of Lilac either on to seedlings of the type or on the Privet. In the case of this latter the union is, as a rule, of short duration, while on seedling Lilacs the suckers from the stock are always a great nuisance. To obviate this M. Lemoine announces that all his Lilacs are on their own roots, which is certainly a step in the right direction.—K. R. W.

Double Narcissus failing.—Last year you advised me how to treat some old-established clumps of Gardenia-flowered Narcissus which had gone "blind." The treatment (weekly doses of liquid manure during the late summer and autumn, and then a mulch of manure for the winter) has been almost entirely successful, nearly all the clumps flowering well, with fine flowers. One clump, however, which a fortnight ago appeared to have eighty-eight buds on it, has refused to respond to the treatment; twenty-five buds were

"blind" and the remaining three are now deformed flowers. Can you give me any further advice? Had I better lift the bulbs and continue the treatment in fresh soil? If so, what is the best time to move them? Up to last year they had always flowered well, and the improvement in all the other clumps is remarkable.—LADY WINIFRED LOWRY-CORRY, *Castle Coole, Enniskillen*.

[We think you had better continue the treatment you have found successful. Leave the bulbs as they are, as this variety dislikes moving.—ED.]

Clianthus puniceus in Bucks.—It is surprising to find there is any trouble about growing *Clianthus puniceus* in Sussex. Here, in South Bucks, on sandy soil, with a wall behind it and shelter from the north and east, it luxuriates, and is just now a mass of flowers. Mild winters bring it on too soon, and then its flowers are injured in early spring, but mats and such like protection damage it rather than help. Our altitude is about 500 feet.—H. H. WORTHINGTON, *Wycombe Court, High Wycombe*.

Horminum pyrenaicum.—Although not one of the choicest alpine plants, this is very attractive when seen in good condition and properly placed. I have been very interested in a group of plants now in full flower. Those in search of easily-grown plants for the rock garden should give this a place. It comes from the Pyrenees, and has dark green, crinkled leaves, which form rosettes close to the ground—after the manner of *Ramondias*—from which issue several spikes of purple flowers on stalks a foot in length. The flowers, borne in whorls of six, hang from the lower side of the arching flower-stalks.—E. M.

Habranthus pratensis.—From Mr. Allan, of the Gardens at Gunton Park, Norwich, we have received as brilliant a flower as ever came to us. It is a Chilean bulb, which few people grow well—myself among them—but which in some places in the eastern counties grows like a Daffodil. Its colour is splendid, and its form, with a little yellowish centre, seems to emphasise the colour. To make it possible to cultivate this more would be a great gain, because it comes in when many of the spring bulbs have gone. The effect in the house is curiously beautiful from every point of view, and yet always brilliant. The plant is well worth growing for its value as a cut flower. Mr Allan writes as follows as to his mode of culture:—"I first saw *Habranthus pratensis* in the Rev. J. G. Nelson's garden at Aldborough, now a good many years ago. He considered it a tender subject, and his directions were:—'Plant at least 8 inches to 9 inches below the surface, and do not disturb the bulbs oftener than necessary.' This method of cultivation has proved to be all wrong. They did not increase, and in heavy soils died out. Mr. Oelee, of Blicking Hall, was the first one, so far as I know, to practise planting it at the same depth as *Narcissi* on a sunny border in lines, and he was rewarded with splendid results—dozens of most brilliant stems of flowers, which were quite a revelation to me on one of my visits at this season of the year (end of May and beginning of June), when it flowers in this part of Norfolk. I lift the bulbs every second year. It is not at all particular as to soil, growing well in our kitchen garden—good sandy loam—on either east or west borders. I have it on both, the bulbs increasing rapidly. The flowers are lovely whilst they last—all too short a period—from two to three weeks.'"

FRUIT.

NOTES ON GRAPE CULTURE.

THE practice of the best Grape growers for market is to get young Vines into bearing in the shortest possible time, give them high culture, crop them heavily, run them about fifteen years, root them out, and start again with young stock. This means a renewal of the borders at considerable expense, but it pays the market man, as he maintains a high quality which can only be obtained from Vines which retain a considerable amount of youthful vigour. How often have we seen an amateur, a gentleman's gardener, come to the front and carry off the principal prizes for several years and then be no more heard of. I can, in the course of forty years, recall several such instances. What has become of him. The answer is simple. The Vines had passed from the heyday of their youth, and though still bearing good crops of nicely-finished bunches, are not capable of furnishing those super-excellent samples termed prize bunches by the gentleman's gardener and specials by the market grower. These big bunches have, however, a limited sale, the demand being for bunches which average a pound weight, but which have berries normal in size and well coloured. The demand for specials is almost exclusively confined to London and the very large towns. In the provinces the fruiterers are seldom asked for them. They like to have variety in size, as many want half a pound only, and the very large proportion of their customers does not want more than a pound at a time. Naturally they prefer to supply whole bunches of the various weights required rather than cut up a large bunch. It is the same in private places. Bunches which weigh from half-a-pound up to a pound and a half, with full-sized berries, are the most serviceable. Such can be obtained from Vines which have been planted twenty and thirty years if the grower will take some pains to neutralise the tendency which the Vine has to push its roots deeply into the ground. When a Vine reaches a certain age the bunches become smaller, and very frequently partial shanking sets in and the berries do not colour well. When this occurs every year it is a sure sign of permanent deterioration caused in nine cases out of ten by defective root action. Faulty culture, such as over-cropping, want of food, and a non-observance of important cultural details, will, of course, lower vitality, but the grower has had sufficient experience to know that he has not committed errors of this kind. He may be certain that the trouble is in the soil. There are doubtless hundreds of Vines in this unsatisfactory condition at the present time, and owners generally know that the best thing to do would be to root them out and renew with young Vines, but amateurs generally are reluctant to do this. They hope things will alter, they do not want to be a year or two without fruit, and there is what at the present time is the chief deterrent—the question of expense and shortage of labour.

That Vines which have come into a very debilitated condition, bearing crops hardly worth the labour of thinning, can be restored to a fruitful condition I have ample proof. I have some Black Hamburgh that have been planted forty years, and some Alicante that were planted twenty-five years ago. Owing to the defective way in which a water-course was made the surface water was thrown back on me for twelve months. The consequence was that my Vine border was

flooded, many of the roots perished, and the following year the crop was not worth ten shillings. It was a heart-breaking affair and 95 per cent. of Grape growers would have rooted them out. I decided to try and renovate them, and in the winter I took out the soil where the roots were decayed and cut them back. Some that had gone down deeply I cut off, leaving a root intact here and there. I then notched the roots—I found very few fibrous roots—at intervals of 4 inches, and bedded the cut portions in peat. Naturally, such drastic treatment caused a check, and growth was weak the following year. I did not renew the soil, but worked in some rotten manure, bones, soot, and lime. This was done about seven years ago and those Vines are now bearing crops which many would be content to have on

NOTES AND REPLIES.

Fruit wall alleys.—The influence of wind and sun has for some weeks past caused the soil in the alleys under walls on which fruit-trees are grown to part with moisture at a rapid rate, and unless rain in abundance should fall very shortly water will have to be applied artificially. The borders beyond the alley are moist enough, but the alley itself is the objective to which attention is directed and which is so often overlooked. Before applying water the surface needs to be lightly loosened with a digging-fork, and if a fruit manure is to be applied this should be sprinkled on top and worked into the soil in the process of digging it. A thin covering of litter or something of a similar nature placed over the full width of

rants have set crops slightly in excess of the average. In the case of these fruits, and of Gooseberries, no signs of fly or of caterpillar exist, so far. Raspberries will, as is usual in these gardens, be a heavy crop, and during the week suckers which had made their appearance in unsuitable places were pulled up.

Morello Cherries.—These are now in bloom. There is now no further danger of frost sufficiently severe to do damage, so the crop is practically assured. Old trees will soon require a dressing of artificial manure to assist them in swelling off the fruits. A number of young trees, planted two years ago, are equally promising, but in their case a mulching of half-decayed manure will, meantime, suffice.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

CLEMATISES RAISED AT LYONS.

C. ROYALE VELOURS, here figured, is a hybrid Clematis raised by M. Morel, of Lyons, but which, unfortunately, the war prevents being sent out. I had the privilege of having some for trial, and among them this very pretty dark velvety one. Quite distinct and a free grower, it is certain of a welcome in our gardens as soon as it may be obtained in the trade. *Huldine* (see illustration, p. 297) is another fine seedling from the same raiser, white with brown exterior. W.

HARDY FLOWER NOTES.

ANEMONE NEMOROSA ROBINSONI.—In order to fully realise the decorative worth of this it must be seen in a broad, healthy mass. I have grown it from the time it first appeared in hardy-flower lists, but until this season have not been able to realise what a fine effect it is capable of creating. I have it in various positions, and in one place it forms a bed several yards square. Last autumn I top-dressed with several inches of Oak leaves, and later on a thin coat of manure was put on. This caused a vigorous growth to be made, the flower-stems being correspondingly strong, and, as they were near a *Thuja* hedge, the blossoms faced one way and they made a brave show. There were hundreds of blooms. Planting in this formal way is not, of course, to be recommended, but in my case I cannot group picturesquely, as my object is rapid increase. Where this *Anemone* is used in a liberal manner I would, however, advise a certain amount of concentration instead of dotting about over a considerable area. I have been in some few well-kept gardens where, however, owing to the dotting about of hardy plants, a considerable amount of monotony prevailed. A garden should, wherever possible, present a series of floral pictures, easily accomplished where there is a considerable area to deal with, and much in this way may be done in gardens of limited extent.

FORGET-ME-NOTS.—I like to see these springing up naturally, selecting, as they seem to do, cosy little spots where they are evidently perfectly happy. Instead of clearing away all the plants as soon as they are out of bloom, let some go to seed, and sooner or later young plants will appear in quite unexpected places where natural conditions prevail. With me this occurs every year. They come up among hardy flowers, under trees and similar places where there is the protection from wind, rain, and frost, and to me they always look happier than when in open beds, where I think the *Forget-me-not* seems out of place. The native species is not an inhabitant of the open fields. We find it in the hedgerows and on the borders of woods, where it enjoys light and sunshine in moderation, but is screened from hot sun. All the *Forget-me-nots* that

The little black Clematis (C. Royale Velours).

Vines not one-fourth of their age. Last year the Hamburg coloured remarkably well, and the berries were well up as regards size. The Alicante was very good, the berries being of maximum size. They were all a good market sample, and I had no difficulty in disposing of them to fruiterers with a good connection. I examined the roots the following year and found that from a large proportion of the notched parts new roots had issued, so that I got active feeders nearer the surface. This gave me the chance to feed heavily, which I did with dung and artificials. These Vines are now the picture of health, with abundant promise of a good crop, and anything more miserable than they were could hardly be pictured. What I have done, others may do.

BYFLEET.

the alleys afterwards prevents the soil again becoming so hard, and at the same time averts undue evaporation. Water in future must be applied whenever the condition of the soil demands it, a fact to be ascertained only by a frequent examination of the same.—A. W.

The Phenomenal Loganberry I sent you a few of should be freely cultivated by those having an orchard-house. We have it now, a strong plant, with four well-grown canes, in a Fig-house, which is not forced. It is now laden with its handsome fruit, which, when allowed to hang to get thoroughly ripe, a good dark red, is most refreshing and delicious. Grown this way, and ripening before the Strawberries are in, it is most welcome.—W. ALLAN, Gunton Park Gardens.

Bush fruits.—In the course of the week a look round was given to the bush fruits; and all over the prospects are gratifying. Gooseberries are, perhaps, scarcely so heavily laden as appeared from a casual glance to be the case; nevertheless, the crop will be quite heavy enough. Black Currants and Red Cur-

I am acquainted with enjoy similar conditions.

FRITILLARIA MELEAGRIS ALBA has a nice effect massed. It is a good thing to use freely among low-growing shrubs, as it does not crave for a great supply of good food, but will flourish for years in poor soil. It is one of the cheap good things that can be bought by the hundred by the not very rich amateur gardeners. With me it springs up here and there from naturally-sown seeds. It is good in the Grass.

ARTEMISIA PEDEMONTANA is one of the most distinct rock plants we have; very desirable, not on account of the inflorescence, which is by no means striking, but by reason of the colour effect which its silvery foliage is capable of creating when appropriately placed. It spreads freely and is hardy, but should be placed well up in the rock garden, so that it can trail over a ledge, and where roots and foliage are ensured against excess of moisture in the resting time.

ARMERIA ALPINA.—I believe that this is the smallest of the family. Any way, it is very dwarf, not exceeding 5 inches in height, and generally not more than 4 inches. It is a delightful little plant, and one of those things so useful to the owners of gardens of limited area, where the rock garden must be on a small scale. All alpine growers naturally wish for as much variety as possible, and should, therefore, avoid those things that spread freely and are of an encroaching nature. Another dwarf species is *Juncea*, somewhat taller, but a good companion to the above.

J. CORNHILL.

DOUBLE WHITE NARCISSUS FAILING.

I AM sending three buds of the double white Narcissus, and shall be much obliged if you can give me any hints as to growing this bulb. Every year the plants come up and are full of buds, looking strong and healthy, and then the buds all wither like those enclosed. Perhaps two flowers in the whole row come out. The bulbs have been in the ground a good many years, but when I have moved a few into a new place the same thing happens. I do not know if we are too high to grow the double Narcissus, as we have very late frost. All other *Dafodils* grow and flower very well. —M. H. CHAMPION, *Edale, Sheffield*.

[The failure of the double white Poet's Narcissus is more or less prevalent each year, and is due to a variety of causes. This Narcissus is a gross feeder, and, therefore, should be well manured. It prefers being planted deeply in the soil, not less than 6 inches, and preferably at 8 inches. A strong, almost tenacious soil is that most suited to its growth and flowering. In light soils, in conjunction with shallow planting, it is usually a failure. The bulbs are impatient of removal, and especially resent being dried off. When replanting is contemplated, this should be done in July, if possible. In digging in the manure—cow-manure and soot are best if your soil is light—keep it 4 inches or 6 inches below the bulbs. The root-fibres of this kind are almost perpetual in character. Bulbs that have stood some time and flowered in the same spot have impoverished the soil, and failure is sure to follow. In such a case, a winter mulching of manure would be helpful. It is not sufficiently recognised that by reason of its late flowering the autumn is approaching before the bulbs are fully ripened off. It is not generally known that the flowers that should appear in May of the present year are really formed and exist in embryo in midsummer of the previous year. It is for this reason that every support should be accorded the bulbs, so that the growing season may be prolonged as much as possible, thereby ensuring the fullest development and the

proper formation of the buds at this time. Not a few regard the "blindness," as this failing is called, as the result of the climatic or atmospheric conditions of the moment, but the true cause is, more probably, insufficient development in the previous year, as, even though blind, all the other parts may be good, and, as such, are produced by the bulb in its season. All you can now do is to encourage vigorous growth by mulching with manure, giving also a good dressing of soot, and, at least, weekly applications of liquid-manure.]

A PERENNIAL DELUSION.

WHEN I was a boy learning gardening a great lady near was always distressed about the scarcity of blue flowers, and tried to get them in all the ways she could. Now, after many years, when some ladies come in to see me they raise pretty much the same lament as to the scarcity of blue flowers or the difficulty of getting them. That was true many years ago, but is not so now, because if it is a question of colour among good garden plants one could name, the blues outnumber them all. There is such a rich store of these that, in fact, it is not easy to enumerate them all in one article. To begin with native plants, there are our true native Forget-me-not and its larger forms, all excellent and deserving of general culture, and there is also the wood Forget-me-not, which is easily naturalised if seed is scattered about grassy places. The trade forms of it differ a little, but are not more beautiful. These Forget-me-nots want no rock garden or other culture as the high mountain kinds might. Then we have the Gromwell (*Lithospermum*), a beautiful plant for a rocky or dry bank. The foreign kinds of this are also very beautiful; some find them slow and difficult, but they are free in sandy soils. A native one—*L. purpureo-ceruleum*—is now (end of May) in fine condition.

The Gentians are the most important alpine family of the northern world, and we have not enjoyed one-half of their beauty yet. If one thinks of the way the common alpine Gentian grows in Ireland and Scotland one is led to think that there are many other beautiful members of the family which may come in. In the south of England it does not do so freely, owing to a lower rainfall. The Willow Gentian, which inhabits the Fir woods of the Alps, is a beautiful plant for half-shady places. The Edinburgh var. of *G. ornata* is also said to be beautiful, and no doubt there are many others coming to us from China and Thibet. The Italian *Anchusa* was half neglected for years until some forms were found that are handsome plants and give us clouds of blue, perhaps best in the wild garden. There is a recent one which has clouds of Forget-me-not-like flowers, and the native *Anchusa* is also a very good plant for rough, grassy places. Where is there a more beautiful blue than that of the Rocky Mountain Columbine?

As I write, the Wistarias, noblest of all climbers, are in beautiful bloom, and Clematises, too, which are sometimes blue, as in the case of *Perle d'Azur*. Of all blue flowers of the spring, perhaps the most charming are the blue flowers that grow in the Grass, as, for example, the British Blue Windflower and the Greek Windflower, and the lovely blue Hepatica. The last I am not sure will grow in our rank Grass, but it deserves a little plantation to itself, slightly shaded for choice. The wild blue form is far better than any double varieties of it. Grape Hyacinths (*Muscari*) come in very well indeed, and often thrive well in Grass but best of all

is the one called *M. conicum*, and there is a native kind of some value.

The Mountain Hairbells that drape the alpine rocks and even grow along the roadways give us a choice of fine things. The handsomest perennial we have is the Delphinium, with its extraordinarily beautiful shades of blue and purple. The varieties of the mountain Violets are most exquisite in shades of colour, and some of them come true from seed and are otherwise easily raised.

The Blue Bindweed (*Convolvulus mauritanicus*) of the North African stony hills I use largely as an edging plant and for draping low walls. The Shamrock Pea comes later for like positions.

And as if we had not enough choice of blue things already, we have lately been endowed with some blue Poppies from the mountains of India, which, for colour and texture, are equal to any flower we have. Our Wood Hyacinth, the Spanish, the vernal Hyacinth of our coasts, and the Italian and Taurian Scillas are among the other beautiful hardy blues.

Annuals and biennials come in to help us, the Cornflower and the handsome wild Chicory of the chalky fields. The blue *Nemesia* is lovely, and gives us in summer the colour of the Forget-me-nots. *Nemophila* is lovely, so is the large blue Pimpernel, best in its rich blue form. So of the Swan River Daisy, best in its blue form. Several other Californian annuals are indispensable, as *Phacelia*, two kinds.

As I write a beautiful blue *Ceanothus* comes in to remind us how fine the *Ceanothuses* are as wall plants. Of this we have excellent proof also in the *Ceanothus Gloire de Versailles*, which, with me, grows well as a shrub, besides being beautiful on walls.—W.

PINKS.

THE season of Pinks will soon be with us, and at their best there are few more acceptable flowers for small beds and borders. As lately noted, they flourish amazingly in many cottage gardens, and make a brave show. My small collection consists of the old Pheasant's Eye, Albino (possibly the best white, as it is such a pure, beautifully-shaped flower, with no tendency to split), Paddington, and a sort very similar to one grown many years ago, and doubtless familiar to older readers of *GARDENING ILLUSTRATED* under the name of Hetty Dean. I never cared much for the large doubles like Her Majesty and Ernest Ladhams. Their beauty was short lived, especially if the season was wet and rough, the flowers split quickly, and the first heavy rain drove them to the ground. One of the prettiest bits in the garden at the present time is the result of associating the old white Pink with clumps of *Viola gracilis*. Few plants have increased more rapidly in favour or become more widely diffused in a short time than this charming *Viola*, and where thoroughly at home, the rich flowers are thrown well above the foliage on long, firm stalks. The foliage, too—a deep rich green that stands remarkably well—is beautiful. Among other plants that associate well with the Pinks are the varieties of *Lobelia cardinalis*, notably that known as Queen Victoria, which has purple-bronze foliage. I find, however, it does not winter satisfactorily outside in this soil, which necessitates lifting at the end of the season, boxing, and replanting in spring. Another plant that may be grown in connection with the Pinks, and that associates well with them, is *Heuchera sanguinea*, also, if space permits, occasional plants of the early dwarf Munstead Lavender.

E. B. S.

Hardwick.

BEAUTY IN HEDGEROW AND MEADOW.

NOTES have often been made as to the beauty of our common white Thorn, and it is strongly in evidence just at present under somewhat peculiar conditions on a stretch of road somewhere about two miles in length. It seems from what I can gather that close on seventy years ago there was a very high overhanging hedge which it was decided to cut, and the person in charge suggested leaving at intervals of about one chain one of the straightest bits that could be found, trimming it into a fairly symmetrical head. These are shapely trees now, a perfect mass of flower, and as the intervening spaces have not been cut for several seasons the whole length of two miles is a white sheet, the occasional trees making a pleasing break in the line. Anything like the above helps one to realise what beautiful effects are produced by what are known as common things, often quite as effective and

them. It will occasionally grow where it is not expected to thrive, and refuses to live in apparently ideal places. It is flourishing and flowering well in the rock garden at Terregles, Kirkcudbrightshire, on an elevated rockery, where, however, it has some good soil about its roots and partially sheltered from the sun. Mr. Reginald Farrer, in one of his books, gives a lively account of his failures and eventual success with this brilliant scarlet-flowered little plant, the successes being attained merely by chance. As a rule, a moist, shady position, such as that advocated in "The English Flower Garden," seems to suit it best.—S. A.

The Water Avens (*Geum rivale*), Leonard's variety.—The type, a native of this country, is found wild by the side of streams in a stony soil, and looking quite pretty when flowering, amid wild Grasses. In cultivation, however, it looks insignificant, but the form known as Leonard's variety is a great improvement and very effective when in bloom, particularly if planted about the level of the eye. The colouring is not nearly so brilliant as in many of the Geums, but it is very pleasing—a sort of dull coppery-red. Though fond of damp places in the wild state, this variety does not seem at all dependent upon moisture, but does well in the rock garden in any open pocket of sandy soil.—N. L.

Epimediums.—Among the late spring hardy plants the Barrenworts are conspicuous. Not only are their blooms freely produced, but the

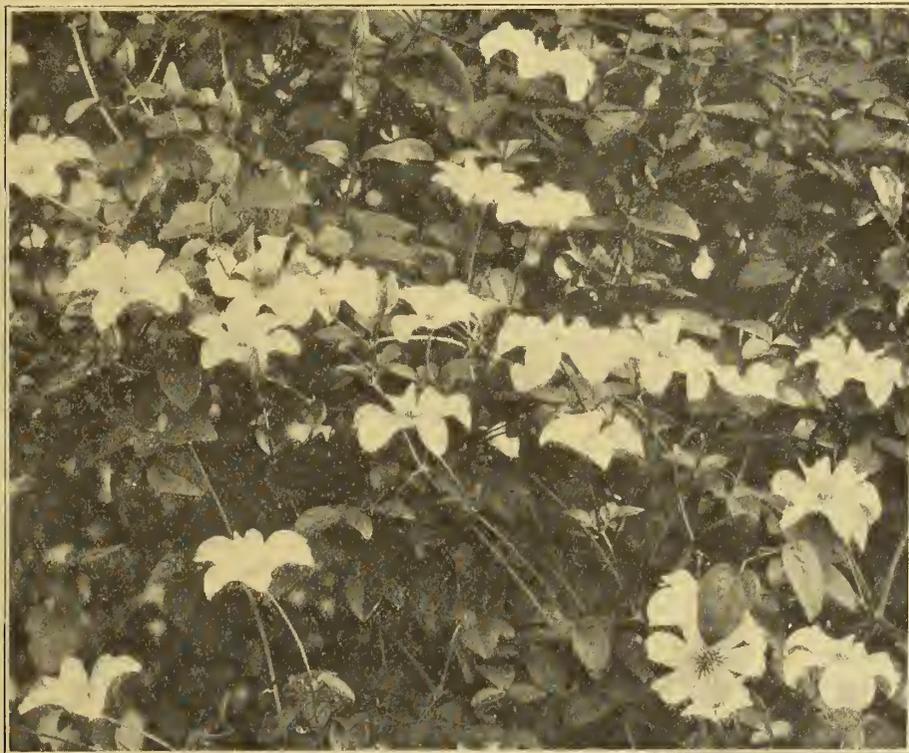

INDOOR PLANTS.

REPOTTING AURICULAS.

WHEN flowering is over repotting may begin. Large pots are not required, those 4-inches in diameter sufficing for the largest examples. The pots must be filled to one-fourth of their depth with drainage, over which is placed a little rough fibrous loam. Clean pots must be used, and those previously employed for Auriculas should be thoroughly washed to remove any of the woolly aphid that may be present. The compost should consist of good fibrous loam three parts and one part well-decayed leaf-mould, to which may be added a little manure from an old hot-bed. A sprinkling of coarse sand will be needed, and some growers add a portion of crushed oyster-shells, but these are not really essential. When repotting, most of the old soil should be shaken from the roots and the woolly aphid destroyed by methylated spirit applied to the pest with a small camel-hair brush. The soil is made fairly firm, and when the plants have been placed in a cold frame facing north, sufficient water must be afforded to wet the whole of the soil. If the frame is not shaded by a building some light material will be required as a protection from strong sunlight. When they are re-established plenty of air must be given, in fact the lights may be removed, especially at night, the dewy atmosphere being beneficial to the plants. Careful watering is essential at all times. During the spring and summer the plants must be kept just moist, but the winter is the most critical period for Auriculas. At this season very little water is needed, and the atmosphere must be kept as dry as possible by opening the lights on all favourable occasions. Dead leaves must be removed directly they will part readily from the stem, and a watch must be kept to prevent water collecting in the heart of the plant.

PROPAGATION.—This is effected by seeds and offsets. The seed should be sown directly it is ripe, and even then it is somewhat irregular in germinating, so it will not be advisable to discard the seed-pan when a few seedlings have been pricked off. Pot the plants on as necessity arises. Seedlings generally reach the flowering stage in about two years. The border Auriculas are all vigorous-growing and should be raised in quantity for the rock garden and flower borders. Offsets are procured in February and August. In the former month all those large enough are removed, but the smaller shoots are left until the latter month. Those offsets, with roots attached, are potted into small pots and then given the same treatment as established plants. A few will be without roots, and these are placed around the side of a pot similar to cuttings, when they will soon become rooted, and may be potted off singly.

INSECT PESTS AND DISEASES.—The chief pests are woolly aphid and green-fly. If the frame is vaporised with some fumigating compound the green-fly will be destroyed, while all the woolly aphid on the soil will also be killed, but this works chiefly underneath, and must be dealt with as described above. The Auricula must never be coddled; cleanliness must be strictly observed. Careful watering and a sweet compost are essential. No manure-water should be given and damp prevented during the winter. B.

Part of a group of *Clematis Huldine*. (See page 295.)

pleasing as the result of elaborate plans. Another long stretch of road will soon be gay with the blooms of the Dog Rose, in varying shades as affected by age and the different positions in which they are growing, not in mass like the May, but in varying heights, from the tall plant that has found its way among the lower branches of a tree to those that are prostrate. Big stretches of Cow Parsley (*Heracleum*) with an undergrowth of Bluebells, wide patches of wood Anemone among ground Ivy and the Dog Violets, Buttercups beneath the taller growths of Sorrel, and tall, feathery Grass above, and the white and red Clover are a few more instances of the beauty to be found just now in field and wood, as well as in the hedgerows. Three things one misses in this neighbourhood so effective on a large scale are Gorse, Heather, and the common Fern.

E. B. S.

Hardwick

Ourisia coccinea.—This handsome Chilean plant is the despair of many gardeners, while others find that it is perfectly happy with

effect of the young foliage is distinctly good. Epimediums are by no means exacting in their requirements, succeeding well in any ordinary garden soil. A further point in their favour is that the plants will succeed quite well under the shade of trees. *E. pinnatum* is perhaps the pick of the family, but *E. alpinum*, *E. violaceum*, and *E. macranthum* may also be relied upon in moist and shady borders.—KIRK.

Corydalis bulbosa.—This is a pretty little species with pale-purplish flowers, which comes into bloom quite early in spring. It is of very neat, dwarf habit, and not by any means showy, but has a quiet, refined beauty which is attractive, and it is doubly welcome because of its early blooming. A sheltered position in well-drained soil suits it, as it is otherwise liable to be nipped by late frosts.—N. L.

Godetia Bijou.—I was very much struck with this Godetia when I saw it blooming last year in a garden in the West of England. It is one of the most showy of all the Godetias, its compact habit being a point in its favour. The plants I saw were covered with lovely rose and white blooms. If the dead flowers are picked off, the plants will flower all the summer.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

Campanula persicifolia Moerheimi.—This has large semi-double white flowers. I well remember having seen some noble plants in a Welsh garden last summer, and was greatly struck by their beauty. The plant varies in height from 2 feet to 3 feet, according to the site, and should certainly be planted near the front of the border.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W. C.

VEGETABLES.

LATE PEAS.

It is useless to sow late Peas on any but deeply-worked and well-manured ground. Therefore, to attempt growing them on soil which has been dug but one spit deep, and where the sub-soil has been untouched, perhaps, for years past, is simply to invite failure. Sown under these conditions the plants will fall a prey to mildew and insect attacks, and finally wither up if the autumn be hot and dry, or, at any rate, yield but indifferently. The best thing to do in cases of this description is, after having marked out the positions where the rows are to be grown, to open out trenches 18 inches wide and the same in depth, in much the same manner as for Celery, and lay the soil out on either side. In the bottom of the trenches place 6 inches of well-rotted manure. On this return some of the soil thrown out, making, when finished, a total depth of manure and soil combined of 15 inches. The trenches will then be filled in to within 3 inches of the ground level, which space is left, with the object of facilitating watering in dry weather and in allowing for a good mulch of half-decayed manure being placed on either side of the rows should the nature of the season render such a precaution necessary. The spare soil left over after preparing the trenches can be levelled down between the rows. The rows should not be less than 2 yards apart, and, if space will admit of their standing 3 yards and 4 yards distant from each other, all the better. The ground between the rows can be utilised, when manured and dug over, for the growing of catch crops, such as Lettuces, Endive, Spinach, French Beans, etc., or it may be devoted, as is often the case, to the growing of Celery. The preparation of the trenches for the Celery and of those for the Peas can then be done at one and the same time.

DWARF OR FRENCH BEANS.

In these days when one is anxious to practise strict economy in the garden in the way of minimising labour and expense, getting as much as possible from a given area, and avoiding waste, there are many things of which it is advisable to sow a small quantity at brief intervals rather than a lot at one time. Among these are Dwarf and French Beans, a useful and profitable vegetable if sown with judgment, but decidedly wasteful when, as often happens, half the crop gets too old to be eatable. Also if the necessary steps are taken to anticipate and retard the season one gets a long time during which this vegetable is available outside, apart from crops obtained from pits or frames. The earliest and latest sowings should be made in one of the warmest spots of the garden, a few stout, forked stakes being inserted at intervals and a light cloth or mat thrown over the rows if frost is expected. A little extra attention is also necessary with the mid-season sowings, especially if the weather proves hot and dry, quick, kindly growth being the principal factor in warding off red spider, one of the chief enemies. At such times the chief points towards successful culture are a deep, fairly rich tilth, a mulching of short Grass or manure, and a liberal supply of water, not necessarily oft repeated, but a good soaking before and after the mulch. The crop should be closely picked to ensure tenderness. Unless the grower contemplates exhibiting and wants a Bean of extra size he will find *Ne Plus Ultra* one of the best. A row

or two or one sowing of Dwarf Green Haricot can be recommended. This is a fine cropper of excellent quality, and if a portion of the crop is allowed to stand and is harvested it will prove a useful and palatable vegetable through the winter. Indeed, so acceptable is it that a special sowing may be made for harvesting, together with one of a dwarf Marrow-fat Pea. E. B. S.

Hardwick.

Runner Beans.—Another sowing of these will be made now in trenches as advised for the earlier sowings. These will come in just right for the later supplies.

GARDEN FOOD.

NOTES AND REPLIES.

The Strawberry unwholesome.—A neighbour of ours could not eat Strawberries. A single one would at once produce nettles-rash, and several meant an illness. That was a curious and unusual idiosyncrasy. The doctor said that there is an acid in Strawberries which predisposes to rheumatism. Is that true, do you think? I only know that Strawberries and cream are very good, but I want the cream and the sugar. Not that I cannot eat the bare berry. I can, and do; but the "ingredients," as they say here, are an improvement.—J. W.

[The doctor was quite right. The late Sir Henry Thompson, the greatest surgeon in his way, told me more than once that he knew of nothing so bad as the common Strawberry for producing lithic acid in the blood. It will surprise many, it is true, and the addition of sugar adds to the evil effects. Having been much among Strawberries, I am inclined to consider this result as a question of kind. The common Strawberry is raised from the Chilean Strawberry, and that is certainly an acid fruit. I have always thought that the alpine Strawberry, which one gets in Switzerland, is better than the English common Strawberry in flavour. One of the best is the wild Strawberry, known as Hautbois (F. elatior), which has a good flavour. It always seemed to me that the British Queen has some of the Hautbois blood in it, as it is free from the sourness of the common kind.—W.]

Dandelion leaves.—These, in small quantities, are a very nice addition to salad, provided the mid-rib, which is very bitter, is not used. The best way is to strip the leaf from the stalk end by running the fingers down it, when it comes away, generally quite easily, from the mid-rib.—SYDENHAM.

ABOUT GOOSEBERRIES.

PERHAPS Gooseberries are the most gladly welcomed of the small fruits. This is no doubt due to the fact that they can be eaten from the time they are large enough to handle, and thus are often the earliest of the fruits to be gathered. Yet, as a rule, the housewife rarely cooks them except in Gooseberry fool, or in tarts, although there are many other delicious ways of serving the fruit.

RATAFIA AND GOOSEBERRY PUDDING is particularly good, and is a change from the usual boiled pudding made with the fruit. First having topped and tailed the Gooseberries, make a nice crust with a cupful (heaped) of finely-chopped butter, two cupfuls of sifted flour, a dessertspoonful of sugar, a pinch of salt, and sufficient water to make into a firm paste. Line a basin with two-thirds of the pastry. Half fill with Gooseberries, sugar to taste, and a grating of Lemon-peel. Cover the Gooseberries with a layer of ratafia

biscuits, and then add more Gooseberries and sugar. Finish with a layer of ratafia. Pour over the whole a wineglassful of port wine and the same quantity of cold water. Cover with the remainder of the crust. Tie a piece of grease-proof paper on top and steam for two hours. Serve with custard or whipped cream.

GOOSEBERRY MOULD is a nice supper dish in the summer. Soak $\frac{1}{2}$ oz. gelatine in a gill of water. Top and tail a pint of green Gooseberries, and simmer them in a second gill of water, with sufficient sugar to sweeten and a piece of cinnamon. When perfectly soft add the gelatine, and stir until it is quite dissolved. Wet a mould and pour the mixture into it; leave till the next day. Turn out and serve with boiled custard.

GOOSEBERRY FRITTERS are rather an unusual dish. Sift 2 oz. flour into a basin, add a pinch of salt, two well-beaten eggs, and four tablespoonfuls of milk or water. Mix the whole gradually, beating well until quite smooth. Set aside in a cool place for an hour. Have ready some large green Gooseberries which have been simmered in sweetened water until tender, but not broken. Add these to the batter and take up three in a spoonful of batter and drop into a hot, buttered pan. Flatten the Gooseberries gently, and when one side of the fritter is delicately browned turn and fry the other side. Send to table piled high on a d'oyly and sprinkled with powdered sugar. A simple and delicious

COLD PUDDING is made with stewed Gooseberries and fine breadcrumbs. Line a mould with thin slices of bread, and fill with alternate layers of stewed Gooseberries and breadcrumbs, adding just sufficient juice to moisten the whole. Cover the top with thin slices of bread and place a dish over all. Set aside to get very cold. Turn out gently and pile whipped cream on top, and send to table at once.

GOOSEBERRY SHORTCAKE is an unusual sweet. Take one large cupful of flour, a heaped teaspoonful of good baking powder, four tablespoonfuls of butter, and rub well together. Add a dessertspoonful of soft sugar and mix to a firm paste with a little water. Roll out very thin and cut into three squares exactly the same size. Place on a greased baking-dish and bake in a moderate oven until nicely browned. Meanwhile, top and tail 1 lb. green Gooseberries, and simmer in only just sufficient water to cover. Pulp them with a spoon, add a little powdered cinnamon, sufficient sugar to sweeten, and a few drops of essence of almonds. Wet a dessertspoonful of cornflour with a little cold water and stir into the mixture. Simmer for five minutes. Place a hot shortcake on a dish, cover with a thick layer of the Gooseberry mixture, place another cake on top and repeat, covering the last layer of cake with Gooseberry mixture, decorating it with tiny roses of whipped cream around the edge. This is a nice hot sweet. If preferred cold, allow the cakes to get cold, and cool the Gooseberry mixture in the square moulds the exact size of the cakes. When cold this will form a green jelly, which can be placed between the shortcakes, the top being decorated with roses of icing or whipped cream. To make

GOOSEBERRY SYLLABUB, stew a pint and a half of Gooseberries in just sufficient water to cover. When perfectly soft rub through a sieve, add sugar to taste, the whipped white of one egg, a gill of cream, and the same of new milk. A few drops of essence of almonds improve the flavour. Whisk the mixture, using an egg whisk, until the whole is very frothy. Serve in glasses, with a spoonful of whipped cream laid on the top. H. THORBURN-CLARKE.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

NOTES AND REPLIES.

Primula pubescens alba.—This, often listed as *P. nivalis*, has been very good this year, though in the somewhat smoky atmosphere of a London suburb it loses its purity after it has been open for a few days. It seems easy to grow, provided it is not allowed to get too dry. It does not seem quite so partial to shade as many of its congeners, and a situation where it gets morning sun without being baked up has suited it very well with me, in an open soil with a fair amount of lime in it. It has a densely-packed head of pure white flowers on a very short stem, which only begins to be visible after the flowers are going off. It was in bloom this year about the middle of April.—N. L.

Saxifraga Elizabethæ.—I find there are two distinct plants bearing this name.

of so deep a green as when grown in shade, but it flowered perhaps even more freely, and made a lovely picture with a few little patches of red and pink Daisies dotted about among it here and there.—N. L.

Mossy Saxifrage Wenlock.—This is one of the best of the now numerous red Mossy Saxifrages. It is perhaps not so deep in colour as some, but the flowers are large, well-formed, and of a good red. It is to be hoped that the number of new varieties sent out which differ in little except name will be more restricted than hitherto.—S. A.

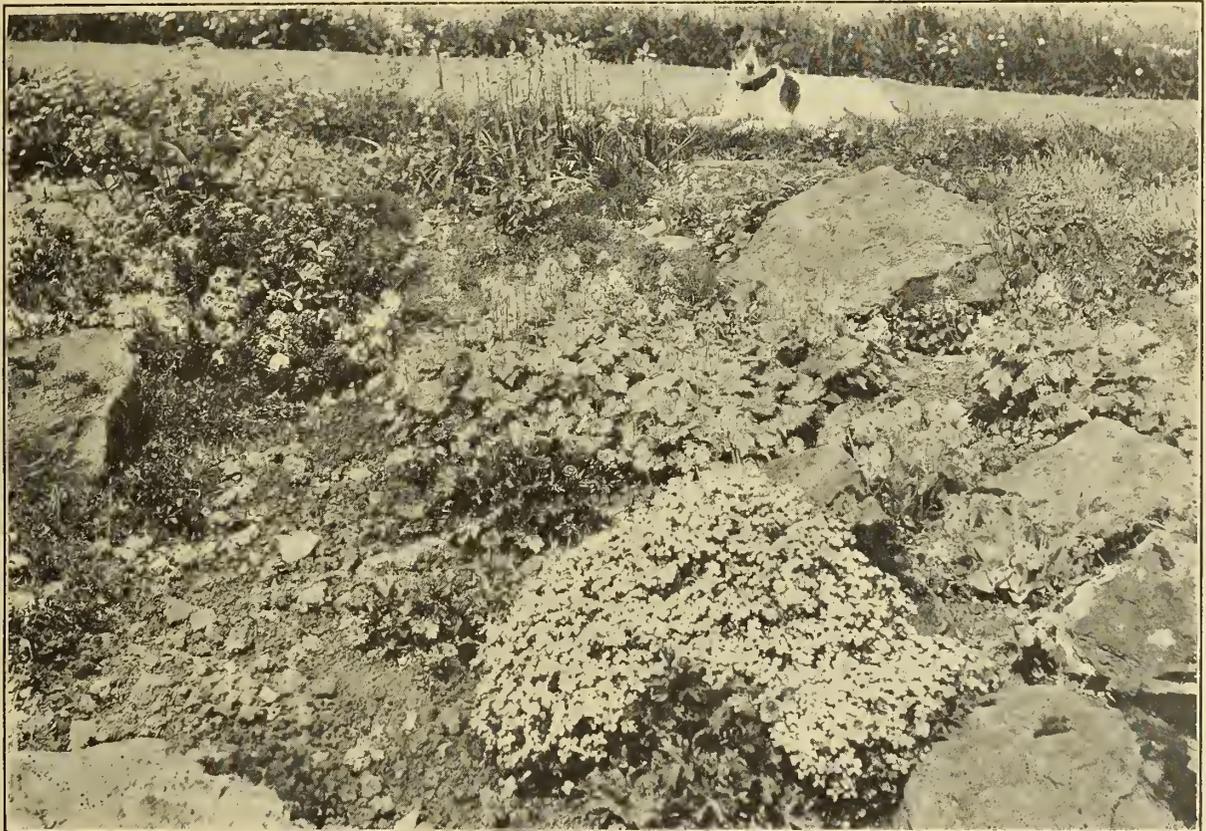

A MODEST ROCK GARDEN.

I HAVE long thought that some of the prettiest results to be had from rock garden plants might often be got in a simpler way than is usual. Most people who make rock gardens pile up the stones in what is usually a very ugly way, and all against the plants, too. Here is an example of a rock garden made by a lady who had no previous experience at all of making rock gardens, and the result is very good. The raised rock-work generally used is not in favour of alpine

FERNS.

POTTING FERNS.
(REPLY TO "PTERIS.")

IN the culture of Ferns much depends upon how they are potted, as well as the condition of the plants when repotted. Ferns should never be disturbed while they are in a dormant state; it is much better to wait until they have started into active growth. If care is taken not to expose them to cold winds during the operation, and a little extra shade given for a few days, the young fronds will not suffer in the least. The old system of using peat and leaf-mould almost exclusively for Ferns is now pretty well understood to be an error. Nearly all Ferns succeed better if some loam is used in the compost, and many may be grown almost entirely in loam. Many of the *Adiantums* will grow freely enough in good fibrous loam, while if potted in peat they refuse to

Rock garden raised only a little above natural level of ground.

The one I have is much closer growing and more compact than the other. It also flowers more freely and is altogether a superior plant. I think *S. Elizabethæ* still one of the best of the yellow Saxifrages of its class in cultivation. It blooms early and is now almost over, but in the shadier places it still gives a sprinkling of its bright yellow flowers, which show up so well against the deep green spiny leaves. I was induced to acquire it largely on the strength of the praise accorded it by a writer on alpinism. I see, however, that it wants a poor soil to enable it to look its best, as, if too highly fed, its foliage is coarse and it flowers with less freedom.—Ess.

The Balearic Sandwort (*Arenaria balearica*).—This grows like a weed in my garden in North London on the north side of rocks, and just now it is studded all over with its white flowers. It needs watching or it will soon choke other treasures if not kept within bounds. Although a shade-lover, I have seen it doing very well rambling over stone steps and pathways in full sun. The foliage was not

plants, but quite against their thriving. Among the plants grown are:—

- | | |
|-------------------------------|-----------------|
| Alpine Phloxes | Foam Flower |
| Daphnes | Rockfoils |
| Pinks | Rock Speedwells |
| Rock Roses | Rock Violas |
| <i>Anchusa myosotidiflora</i> | Cinquefoils |
| Edelweiss | Aubrietias |
| Gentians | Alpine Poppies |
| Alpine Auriculas | Stonecrops |
| Lithospermum | |

W.

Ethionema iberideum.—In the moraine, *Ethionema iberideum* is flowering freely, the white blooms associating well with the glaucous foliage, and the general effect is quite attractive. These Lebanon Candytufts are not nearly so much grown as they should be by cultivators of alpine plants. They generally thrive well in loam, sand, and leaf-soil, with a little lime rubbish, some of the last of which is in the moraine in which the plant referred to above is growing.—S. ARNOTT.

Saxifraga L. G. Godseff.—This, one of the freest and best of the yellow-flowered Rockfoils, is again in bloom. The precise parentage of this hybrid I do not know. If I dare hazard a guess, I should suggest as its parents a good form of *S. Burseriana* and *S. apiculata*, although it is even brighter than the latter in its shade of yellow. I find it grows better in a moraine than on the rock garden.—Ess.

make any progress, not perhaps because there is anything objectionable in peat, but because it gets sour through excess of moisture. If the loam is too heavy a little fibrous peat may be used with advantage, but we prefer to limit its use as much as possible.

An important point in potting Ferns is to keep the crown of the plants well down on to the soil, more especially in the case of those sorts which make new roots just below the crown. The *Aspleniums* will soon get weakened if not kept low enough for the new roots to take hold of the soil. The same may be said of many of the *Pterises*, *Gymnogrammas*, etc. All the vigorous-growing kinds which root freely should be potted loosely, and those with less vigour and slender roots should have the soil pressed moderately firm. The *Davallias* and others which have the rhizomes on the surface require more drainage, as the roots do not penetrate so

deeply, and the lower portion of the soil is liable to get sour through the constant watering required to keep the surface moist. Shallow pots or pans are best for growing all such sorts as do not root deeply, and for those which have the rhizomes spreading under the surface, either wooden or wire baskets should be used. In the case of all the delicate small-growing Ferns care should be taken not to overpot them; large pots for small plants are very unsightly, as well as injurious to the health of the plants, and in no case does this apply more forcibly than to Ferns.

ROSES.

ROSES FOR WINTER EFFECT.

MANY of the Rose species are very useful for winter effect because of the beautifully-coloured wood, foliage, and fruit, one of the best being

ROSA RUBRIFOLIA, or ferruginea, as it is also called. During the summer this is invaluable for indoor decoration, the lovely, tender, plum-coloured foliage being charming when arranged in vases with various flowers. The mauve-coloured blooms are insignificant, but they give a profusion of dark-red hips, which will hang all winter unless the birds take them. The deep mahogany-tinted wood is beautiful.

ROSA LUCIDA is valuable in the late autumn, when its shiny foliage assumes a brown-red hue, giving a lovely effect in conjunction with the ruddy stems and branches. In

ROSA MOYSEL, a recent introduction from China, the flowers are of a curious shade of violet-red, followed later by the grey-green wood is effective in the winter.

ROSA RUGOSA and its forms are largely used in woodlands, where the large, single, red or white blossoms show up beautifully, and fill the air with their sweet scent. Both *R. rugosa alba* and *rubra* produce very large bright-red fruits, which are much appreciated by game, and are often planted for that purpose. The variety *Blanc double de Coubert* does not fruit so freely, but is beautiful in the early winter, when its luxuriant foliage takes on a pure golden tint. The scarlet-red bark of

R. PIMPINELLEFOLIA BLANDA vies with the red Dogwood in richness of tint, making a pleasing object during the winter, while

R. POMIFERA is valuable on account of its masses of large scarlet fruits. It is seldom realised that our own native

R. CANINA is one of the most prolific, and also among the most picturesque, of fruit-bearing Roses.

R. MALYI has wood of an attractive violet-red hue, while

R. SERTATA, a new introduction, makes a handsome, bold shrub with bronzy-tinted wood covered with innumerable straw-coloured spines. A hedge or bold group of either of the last two species is beautiful during the winter. *R. Malyi* bears large single blossoms of a pale mauve tint early in the season. The

PENZANCE SWEET BRIARS quickly grow into bushes 8 feet to 10 feet high, and as much through. Besides being beautiful when in flower they are equally so in the winter, when covered with masses of bright-red hips.

There are also numerous garden varieties which possess handsome bark, foremost among them being the old Bour-saults, Amadis, and inermis Morletti, each of which has smooth, practically thornless wood of an effective reddish tinge. Other beautiful Roses possessing

handsome bark are the lovely old fragrant Bourbon, Zephirin Drouhin, the wonderful Hybrid Austrian, Louis Barbier, the Hybrid *R. rugosa* Carmen, the wood of which is covered with bloom like a plum, and Adrian Riverchon, a perpetual-flowering hybrid musk. Among the more vigorous Ramblers there are Tea Rambler, Ariel, Shower of Gold, Source d'Or, and Tausendschon.

There are no true evergreens among the Roses, but many varieties retain their foliage until a late date, especially in a mild winter, the most conspicuous in this respect being American Pillar, Edmund Proust, Shower of Gold, Robert Craig, and Alberic Barbier among the Ramblers, Monsieur Desir, Climbing White Maman Cochet, and Aimee Vibert à fleurs jaunes among the pillar Roses, and Mme. Antoine Mari, Lady Plymouth, Iceberg, and Agate among dwarf-growing varieties. Aimee Vibert à fleurs jaunes is particularly handsome. The better-known white-flowered Aimee Vibert also retains its foliage well, but I have not found it equal to the yellow variety. One of the prettiest Ramblers to grow for winter effect is Rubin, which is well named, for besides bearing masses of bright-red blossoms in the summer the wood has a delightful ruby-red tint, while the young growths, which often appear in January, are of a brilliant crimson. E.

H.T. Rose Mrs. Chas. E. Pearson.—This is likely to become popular with northern growers. I like the colouring of orange tinted with apricot, red, fawn, and yellow, while its habit is excellent, the flowers being well held up to the eye. It has also that indispensable charm in a good Rose—a delightful perfume.—*SCOREA ROSE.*

Autumn Roses in Spain.—Richard Le Gallienne, in "My Castel in Spain," says, "There would be no autumn in my garden." Would someone acquainted with that sunny land tell us whether September Roses bloom there?—*WALTER GYLES.*

GARDEN PESTS AND FRIENDS.

Carnation leaf-spot.—I am sending you some leaves from a Perpetual Carnation plant. Could you kindly tell me what the disease is and what to get to stop it?—*WILLIAM JACKSON, Huddersfield.*

[Your Carnations have been attacked by what is known as the Carnation leaf-spot, caused by a damp and stagnant atmosphere, sodden or unsuitable soil, a severe check in some way, or the overcrowding of the plants. Give as much light and air as possible, cut away the affected leaves, and put the plants into a dry, warm atmosphere to force them into growth. This disease is most troublesome in wet, cold seasons.]

Peach-tree leaves injured.—I enclose some leaves from a young Peach-tree, under glass, and will be obliged if you will let me know the cause of the spots on them and what should be done to prevent it.—*E. A. Cox.*

[The leaves you send have been attacked by the shot-hole fungus (*Cercospora coccinea*), a common pest in orchard-houses. Pick off and burn the affected leaves, and when the leaves fall in the autumn collect them and burn them. It would also be well before the buds open in the spring to remove the surface soil to the depth of an inch, so as to make sure that no spores are left anywhere near the trees. As soon as the new leaves begin to expand spray the trees with an ammoniacal solution of carbonate of copper made as follows:—Take 1 oz. of carbonate of copper and make it into a thin paste with a little water, then add to it slowly 1½ pints of the strongest ammonia. When all the copper carbonate is dissolved a deep, clear blue liquid should be the result. This, when diluted with nine gallons of water, is ready for use. Spray three times, or oftener if necessary, at intervals of a week.]

TREES AND SHRUBS.

THE YEW POISONOUS.

I AM sorry to see "E. B. S." (page 284) is inclined to sit on the fence about the deadly nature of the common Yew. There is no viper or asp of America or India more deadly in its effects. Let "E. B. S." consult any standard book on poisons in French or English. The escapes from the effects of this deadly tree are frequent, no doubt. They may be due to the trees being tall and out of the way of stock, or to causes that cannot be otherwise explained, and often stock will escape for some years and another time will all, perhaps, perish. It is an error to suppose that only the clippings of the tree are poisonous; the fresh young tree itself has killed valuable animals in my own place, and thousands of horses and cows have been killed in the same way. Young architects and pretended landscape gardeners scatter miles of Yews about country places, which is a most dangerous proceeding. It is rank carelessness to let any Yew-tree be anywhere within reach of stock. If the tree has a clean stem it may be considered safe, especially in a wood, but the rule should be never to put a Yew anywhere an animal can get to it. The tree is so very beautiful when old that one must keep it always in its right place. W.

NEGLECTED PLANTING.

THERE is an article in *Country Life* by a practical Scottish timber man, Mr. T. B. Jones, from which, as it does not deal with vague generalities as such articles so often do, we take a few of the most suggestive paragraphs. There is a great area of poor land which would be much better planted with fast-growing native trees. For firewood alone it would be worth our while to plant in districts where wood is scarce or nearly absent, as it is in some districts.

"With reference to Sir Robert Lorimer's article, entitled "The Neglect of Home Timber," permit me as a Scottish home timber merchant to give expression to a few opinions and suggestions.

That home-grown Scotch Fir and Spruce pitwood for mines, if selected and seasoned, is equal to foreign pitwood.

That battens cut from selected Scotch Fir and Spruce are equal, and often superior, to foreign redwood and white-wood.

That selected Larch is suitable for practically every purpose where Pitch Pine is specified, and at the same time possesses two great advantages, viz., greater strength and durability.

SUGGESTIONS.—The replanting of natural woodlands of not less than ten acres in extent to be compulsory upon owners within seven years of a clean cut, given suitable soil and altitude. Soils too poor for agricultural purposes can usually be profitably employed for afforestation.

If replanting is not done by the owners of land within seven years, the State to replant at its own expense. The State to give six months' notice of its intention to replant, and if no guarantee is given by owners within six months of notice being received that they will proceed to plant, then the State shall do so.

Owners of land to have the option for twenty years after planting being done of repaying the State the cost of planting, including interest and compound interest to date of repayment.

If option is not exercised by owners within twenty years, the planted area, on payment to the owners of a sum calculated upon the original annual agricultural value, ascertained by mutual agreement

previous to planting, to become the absolute property of the State. If, however, it was proved to the satisfaction of impartial experts that the State planting had not been justified by results, the optional period to be extended, but if the State did not care to proceed further with planting experiments, then owners to have the right to resume full possession of their land.

State demonstration areas to be opened all over the United Kingdom and Ireland. A certain species of tree may prove a wonderful success in some parts of the country, and be an absolute failure in other parts. The Oriental Plane, for instance, although sub-tropical, grows luxuriantly in the London streets. The same tree, however, does not thrive in the north of Scotland. If a sub-tropical plant like the Oriental Plane thrives in the

AZALEA VASEYI.

THE gardens of Europe are full of Azaleas of manifold kinds and regions, mostly very handsome and useful, but one of the most beautiful of all is a rather recent discovery in America—*A. Vaseyi*. It is quite hardy with us, most delicate in colour, and no doubt will be largely used by the hybridisers, though it is one of those things which we think they had better leave alone. The wild types of Azaleas are as pretty as any hybrids raised from them, and it would be difficult to beat this one.

NOTES AND REPLIES.

The dwarf Blueberry (*Vaccinium pennsylvanicum*).—The various Whortleberries or *Vacciniums* are not often grown in gardens, although several of them are

been given the distinctive name of *leucocarpum*. For the wilder parts of the garden or for planting in large masses in parks it might well be given attention, and is quite in place associated with *Rhododendrons* and *Heaths*. It is a deciduous shrub, the leaves appearing about the time the flowers fade.—D.

Leptospermum scoparium Nicholli.—This differs markedly from the type. As a rule, in the favoured parts of this country, the typical kind forms a freely-branched bush, the flowers usually white and borne very freely. At the International Horticultural Exhibition of 1912 the variety *Nicholli* was first brought prominently before the public, though it was known previous to that, having been discovered in the neighbourhood of Christchurch, New Zealand. It differs from the species in being somewhat more stiff in

Flowering shoots of Azalea Vaseyi.

south of England, may not a tropical plant like the valuable Teak also thrive? State demonstration areas would settle such questions.

The Death Duties to be revised, in order to encourage the planting of timber. At present a heavy death toll is taken upon all land. Owners usually find that to meet this toll they must either part with real estate, such as shares, live stock, and growing timber, or mortgage their property. The standing timber is frequently taken. It is obvious that the very reason that necessitated the cutting of the timber operates to prevent replanting. Common sense suggests that taxation on agricultural land should not be greater than it can reasonably bear, and that to rob Peter the Forester to enable Paul the Agriculturist to pay excessive taxes to the State Collector is very bad business."

worth a place. The reason for their exclusion from many gardens lies in their somewhat exacting requirements, for it is only in certain places that they give good results. Light soil, containing peat, free from lime and permanently moist, suits them best, and, provided the root conditions are moist, they do not object to full sun. Partial shade, however, suits them also. As a rule, the plant under notice grows from 1½ feet to 2 feet high, forming a dense mass and bearing during April and March a large number of bell-shaped flowers in colour creamy-white suffused with pink. The berries, black with a bluish bloom, can be used for cooking in the same way as the fruits of the common Bilberry of our hills and commons. It is a native of the eastern United States, where several distinct forms are found, including one with white fruits that has

growth, while the leaves have a reddish tinge. The main distinctive feature is, however, in the colour of the blossoms, which are of a rich ruby-red tint. Other varieties were also shown and received Awards of Merit, namely, *L. s. Chajmanni*, with rosy-red blossoms, and *L. s. Boscaweni*, much looser in habit than the other two, while the blossoms are larger, almost white, with a red centre, the buds being red. In the south and west of these islands the *Leptospermums* are charming outdoor shrubs.—K. R. W.

The double-flowered Gorse.—Some care should be taken in choosing a position for the double-flowered Gorse, which, however desirable, when established increases too much at the root and encroaches upon its neighbours if in congenial quarters. It is certainly more compact than the single form, and blooms for a long period. It should be planted where it will not harm anything when allowed to spread.—Ess.

ROYAL HORTICULTURAL SOCIETY.

JUNE 6TH, 1916.

THE meeting of the Society on the above date was of a quite representative character, examples of many prominent departments of garden and greenhouse being on view. The object-lesson of the meeting, however, centred in the superb group of Snapdragons staged by Messrs. Dobbie and Co., Edinburgh, which also demonstrated the perfection attainable when cultural skill of the highest order is directed to a particular flower. Finer produce we shall probably never see. In other directions Sweet Peas played a prominent part, while Pæony, Pyrethrum, Poppy, and Iris contributed their quota here as they are doing now in larger measure in the garden. Roses and Carnations were below the average; also alpines. Flowering shrubs, on the other hand, particularly Rhododendrons, were in good form. Several Orchid groups were staged, and of these and hardy plants, novelties of more than ordinary interest and importance received recognition.

SNAPDRAGONS AND SWEET PEAS.

Of these nothing finer than the Gold medal group arranged by Messrs. Dobbie and Co., Edinburgh, has ever been seen at any exhibition. Perfectly grown and imposingly as well as ideally staged, they were in the nature of a revelation. In the case of the Antirrhinum what appealed to us most strongly, apart from colour richness and diversity, were the exceedingly fine proportions of the flower-spikes and the perfect condition of the blooms, which the foot-long spires revealed to advantage, and surely nothing could assist to a greater popularity a justly popular garden flower than the perfection here attained. Tall, medium, and Tom Thumb varieties were alike well flowered. From a large collection we selected Yellow King, Yellow Queen, White Queen, Golden Morn (yellow and red), Cottage Maid (rose), Coccinea (the most brilliant red), and Noble (a bicolor of crimson and white). These are tall or medium growers. Tom Thumb sorts were in white, yellow, and crimson shades, and of special value for beds alone or as a margin to the taller sorts. Of Sweet Peas there were four dozen or so of selected varieties, Blue Picotee (white, finely-margined blue), Dora (recently certificated), and Anzac (of mahogany-red and heliotrope). These are novelties for the ensuing year. Another excellent lot of Sweet Peas was staged by Messrs. Bide, Farnham. In this, Farnham Lavender was one of the best. It is of good size and of decided colour. Lady Hunter (salmon, tinted apricot), President (scarlet), Ruth Bide (rose), Marks Tey, and Constance Hinton (white) were other very fine sorts. Messrs. R. and G. Cuthbert, Southgate, N., showed pot-grown Antirrhinums; also large groups of Clarkias.

HARDY HERBACEOUS FLOWERS.

To this section Mr. J. C. Allgrove, Middle Green, Langley, Slough, contributed not a few good things, and among them many species of Primulas in sensible groups. Of these we remarked the rich red Unique, Beesiana, Bulleyana, Sikkimensis, Cockburniana, Mrs. Berkeley, capitata, and others. Iris chrysographis (a new grassy-leaved species from Western China of imperial purple colour), Anthericum (Chrysobactron), Hookeri (yellow), and the curious red-flowered miniature Columbine (Aquilegia ecalcarata) were others of interest or merit. Anchusas were brilliant, while above towered the noble spires of the Eremurus. Near by

Mr. Amos Perry, Enfield, had an exhibit aglow with the brilliance of oriental and other Poppies, the rather dwarf-growing and small-flowered L'Unique being one of the more striking, and jagged of petal to boot. Mrs. Perry, Perry's Favourite, and Lady Moore were others. Iris sibirica Perry's Blue was very beautiful.

Messrs. Kelway and Sons, Langport, with two parallel-placed tables arranged an avenue of Pæonies and Pyrethrums, the whole a striking tribute to the wealth and beauty of these showiest of early summer flowers. We thought the single Pæonies very fine, and selected Mafeking (crimson), Emily and Jura (rose), Wilbur Wright (maroon-crimson), and Flag of Truce from out of an extensive lot.

Mr. F. Gifford, Montague Nursery, Hornchurch, Essex, showed a particularly fine lot of Pæonia albiflora grandiflora, the beauty of whose single white flowers is enhanced by a great cluster of golden anthers.

Messrs. George Jackman and Sons, Woking, contributed among other things a considerable variety of Irises. Bakers, Limited, Wolverhampton, showed Pyrethrums freely; also the very charming Pentstemon glaber roseus and Viola Valderia, a lovely blue alpine species.

Mr. G. W. Miller, Clarkson Nurseries, Wisbech, had a big lot of the single, white, golden-anthered Pæonia Whitleyi major; also Pyrethrums Pericles and Queen Mary, single yellow and double pink flowered respectively.

Messrs. R. W. Wallace and Co., Colchester, staged a collection of the finer-bearded Irises, but which, owing to the stormy weather immediately preceding the show, hardly did them justice. King of Irises (yellow and crimson), Isoline, Groust (rosy-mauve), Alcazar (one of the most imposing), Albert Victor (a fine pale blue pallida), and Kashmir (white) were some of the best. Iris sibirica Emperor (intense blue) was noteworthy.

ALPINES.

The most beautiful plant in this section was Meconopsis simplicifolia, Bailey's form, sent from the Edinburgh Botanic Gardens by Professor Balfour Balfour. The lustrous, sky-blue, saucer-shaped flower, 3 inches across, enhanced in beauty by a boss of golden anthers, appealed to all. Another very beautiful and remarkable plant—whether alpine or not we know not—from the same source was Monocharis pardanthina. It has pendent, reddish, Lenten Rose-like blossoms on Lily-like growth less than a foot high. Both gained first-class certificates.

Messrs. Waterer, Sons, and Crisp, Bagshot and Twyford, showed the lovely Dianthus neglectus, Wargrave variety (of taller growth than the original, and very beautiful withal). D. Spencer Bickham (a lovely alpine pink dowered with rosy-crimson flowers), Pentstemon heterophyllus (a fine blue alpine species), and Silene alpestris grandiflora plena were some of the more beautiful.

Mr. G. Reuthe, Keston, Kent, contributed Allium pedemontanum in two distinct forms; also Primula reticulata, whose flower effect is that of a pale P. sikkimensis. It is, however, quite distinct and beautiful. Rhododendron Keysi and R. strictum glaucum (white-flowered) were remarked.

ROSES.

We have seen these much finer. The best group was that from Mr. Elisha Hicks, Twyford, who staged particularly good stands of the large semi-double, white, climbing variety Una, whose saucer-formed flowers are each nearly 4

inches across. Alberic Barbier (yellow), Louis Barbier (salmon-pink), and the new Hybrid Tea, Henrietta, of orange-salmon tone, were others in the group. The best stands from Messrs. B. R. Cant and Sons, Colchester, were Silver Moon and Cupid, single white and single pink respectively. Mr. George Prince, Oxford, showed Louis Barbier, the Austrian Briars in variety, and the double yellow Harrisoni. A new climbing Rose, Lady Gwendoline Colvin (coloured salmon and apricot), was on view from Messrs. Chaplin Brothers, Waltham Cross. It is distinct and very freely flowered.

FLOWERING SHRUBS.

Messrs. Waterer, Sons, and Crisp, Bagshot, arranged a highly meritorious group of Rhododendrons, three of which—Donald Waterer (rosy-white), Duchess of Teck (rose-pink), and Dipole Pink (deep rose)—gained awards. Lady Decies and Mum (white) were also very good. Some well-flowered plants of Kalmia latifolia were very beautiful.

Messrs. J. Cheal and Sons, Crawley, had cut specimens of the rare Magnolia parviflora, Leptospermum Nicholii, Abutilon vitifolium, Kalmia rubra, and Azalea coccinea rubra, among others.

Mr. Charles Turner, Slough, brought a collection of Deutzias and Philadelphuses. Of Deutzias, Avalanche and hybrida erecta were the best. D. scabra (Thunberg) is an interesting species, having white, orange centred flowers. The best Philadelphus was the double-flowered Avalanche, whose colour purity is remarkable.

GREENHOUSE PLANTS.

Messrs. Stuart Low and Co., Enfield, were the only exhibitors of Carnations. These were largely of the Malmaison type, Princess of Wales, Lady Coventry, Hon. Charlotte Knollys, and Mrs. Myles Kennedy being on view.

From Messrs. H. B. May and Sons, Edmonton, came a considerable variety, Hydrangeas in red, white, and blue, Fuchsias and Ivy-leaved Pelargoniums, chiefly in well-flowered standards, Verbenas, and much else. The red-tinted Adiantum Veitchi was very good.

Messrs. Peed and Sons, West Norwood, contributed a table length of Gloxinias of a capital strain, in which the spotted varieties were a feature. Self-coloured sorts in white, crimson, purple, and other shades were very good.

Messrs. H. Cannell and Sons, Eynsford, showed the new Ivy-leaved Pelargonium Kathleen Bunyard very finely. The flowers are self-scarlet and the plant is a most profuse bloomer. Begonia Major Hope, one of the best dwarf double-flowered bedding Begonias, and of clear salmon tone, was very good.

ORCHIDS.

The most interesting novelty was the tri-generic hybrid Wilsonara insignis (Oncidioda Charlesworthi and Odontoglossum illustrissimum). It is in effect a crimson, starry-flowered Odontioda. It came from Messrs. Charlesworth and Co., Haywards Heath, and gained an Award of Merit. This firm also showed many good Cattleyas, among them C. Mossiae Wageneri (very fine white).

Messrs. Sander and Sons, St. Albans, had, among others, a big specimen of Cattleya Mossiae, carrying about ten flower-spikes.

Messrs. Hassal and Co., Southgate, N., showed Cattleya Mossiae Olympia with Cypripedium Chamberlainianum, a well-flowered group of C. Lawrenceanum Hyeaunum (Bank House variety) coming from Mr. F. Menteith Ogilvie, Oxford.

Dr. Lacroze, Roehampton Lane, showed *Miltonias*, *Cattleyas*, and *Brasso-Cattleyas*. In a group from Messrs. Stuart Low and Co., *Remanthera Imschootiana* (scarlet) and *Cattleya Schilleriana* were the chief items, while in that from Messrs. Flory and Black the white *Cattleya Mossiae* Wageri was noteworthy.

FRUIT.

The only exhibit consisted of gathered fruits in boxes and fruiting examples in pots of the richly-coloured Strawberry Laxtonian, sent by Messrs. Laxton Brothers, Bedford. The crimson-coloured fruits are of excellent flavour, the plant a great cropper.

A complete list of the plants certificated and the medals awarded will appear in our next issue.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM JUNE 1ST.—*Siberian Pea-tree* (*Caragana arborescens*), *Slubby Spiræus* (in variety), *Native and American Thorns*, *Brooms* (various colours), *Rubus nathanus*, *Rocky Mountain Bramble* (*R. deliciosus*), the *Judastree* (*Cercis Siliquastrum*), *Wistarias* (in variety), *Magnolias* (several), *Mountain Clematis* (species and varieties), *Coronilla glauca*, *C. Emerus*, *Deutzias* (in variety), *Broad-leaved Spindle-tree* (*Euonymus latifolius* planipes), *Solanum crispum*, *Lilacs*, *Jew's Mallow* (*Kerria*) (single and double), *Polygonum baldschuanicum*, *Roses* (bush and climbing), *Azaleas* (in great variety), *Rhododendrons* (in great variety), *Pyracantha Lælandi*, *Egle sepiaria*, *Mexican Orange* (*Choisya ternata*), *Pyrus Malus* (various), *Laburnums*, *Evergreen Laburnum* (*Piptanthus nepalensis*), *Cydonias* (various), *Rosa* (many species), *Berberis* (several), *Olearia macrodonta*, *Kalmias*, *Elæagnus*, *Partridgeberry* (*Gaultheria Shallon*), *Andromeda Catesbæi*, *Periwinkles*, *Honeysuckles*, *Jasminum Beesianum*, *Yellow Jasmine*, *Fendlera rupicola*, *Daphnes* (in variety), *Sun and Rock Roses*, *Rock Spray* (*Cotoneaster*) (various), *Robinia Kelseyi*, *Diervilias* (in various colours), *Viburnum plicatum*, *V. Opulus*, *Genista Sullana*, *Allspice-tree* (*Calycanthus floridus*), *Hardy Heaths* (in variety), *Menziesias* (in variety), *Pernettyas*, *Sand Myrtle* (*Leiophyllum burifolium*), *Cornus florida*, *Rhus Cotinus*, *R. codonodes*, *False Heath* (*Fabiana imbricata*), *Grevillea rosmarinifolia*, *Celastrus articulatus*, *Crimson Chestnut* (*Esculus Briotti*), *Ribes speciosum*, *Coriaria japonica*, *Leontopodium* (in variety), *Cheiranthus linifolius*, *Sedum cæreuleum*, *S. spatulifolium*, *Isolirion tataricum* *Pallasi*, *Androsace lanuginosa*, *Linarias* (in variety), *Woodruff*, *Hypericum reptans*, *Myosotis sylvatica*, *Giant Summer Forget-me-nots* (in variety), *Siberian Iris* (various), *German Iris* (in several varieties), *common Water Flag*, *Nuphar luteum*, *N. Advena*, *Nymphæas* (in variety), *Ranunculus aquatilis*, *Globe-flowers*, *Day Lilies* (in variety), *Tradescantia virginica*, *Geums* (several), *Horminum purenacium*, *Salvia acaulis*, *Lychnis diurna*, *Potentillas* (in variety), *Linum arboreum*, *L. alpinum*, *Dic-tamnus Frazinella* (in variety), *Campanulas* (in variety), *Eremurus Bungei*, *E. himalaicus*, *Geraniums* (in variety), *Virginian Cowslip* (*Mertensia virginica*), *Asphodelus luteus*, *Larkspurs* (in variety), *Poppies*, *Star of Bethlehem* (*Ornithogalum*), *Solomon's Seal*, *Lily of the Valley*, *Gromwells*, *Lithospermum* (in variety), *Arenaria*, *Mossy and Encrusted Saxifrages* (in variety), *Aubrietias* (in variety), *Anchusas* (in variety), *Tree Lupins* (various), *Lupinus polyphyllus* (in great variety), *Herbaceous and Moutan Pæonies*, *Meconopsis cambrica*, *M. sinuata latifolia*, *Columbines*, *Tufted Pansies* (in great variety), the *Snowdrop Anemone* (*A. sylvestris*), *Erigerons* (in variety), *Sweet Williams*, *Rodgersia* (various), *Camassias* (in variety), *Libertia formosa*, *Alliums*, *Fog-gloves*, *Heucheras*, *Gypsophila prostrata* (in variety), *Achilleas* (in variety), *Helichrysums*, *Erodium Manescavi*, *Dianthus deltoideus ruber*, *Canary Creeper*, *Æthionemas*, *Ipomæas*, *Antennarias*, *Hyacinthus amethystinus*, *African Lily*, *Transvaal Daisy* (*Gerbera*) (various), *Maiden Pinks*, *Mule Pinks* (various colours), *Alpine Phlox* (in variety), *Oxalis* (in several colours), *Monroe's Mallow*, *Gazania splendens*, *Fuchsias* (various), *Veronicas*, *Cornus canadensis*, *Muehlenbeckia complexa nana*, *Meadow Rue*, *Trilliums* (various colours), *Armerias*, *Silene sylvestris*, *Crambe cordifolia*, *Homeria collina*, *Dicentra spectabilis*, *Gladiolus byzantinus*, *Aquilegias*, *Wahlenbergia serpyllifolia*, *Candytuft*, *Collinsia grandiflora*, *Saponaria ocyroides*, *Dryas octopetala*, *Paronychia polygonifolia*, *Epilobium nummularifolium*, *Nepea Mussini*, *Everlasting Pea* (in variety).

WORK OF THE WEEK.—*Hepaticas* are now growing freely. The cutting and cleaning up of Grass edgings have taken up considerable time, but such work adds greatly to the appearance of the garden and well repays the labour spent upon it. Two small beds have

been planted with *Snapdragon Nelrose*, and the same variety has been planted as a carpet to clumps of *Sweet Peas*. *Verbena Princess of Wales*, a beautiful purple variety, has been put out at the end of a bed of *Roses*, and a mixture of *Verbena Rose Queen* and *V. Bluebell* has been planted to wind about among groups of *Sweet Peas*. A further plantation of *Cardinal Lobelias* has been made to complete a large bed and a small group has been added to the mixed border. *Green-fly* has made its presence felt so strongly on *Roses* and summer-flowering *Forget-me-nots* that evenings and early mornings have been given up to spraying these plants. One good dose of *Quassa extract* practically cleanses the plants. A few plants have been added to the rock border, including *Sand Verbena* (*Abronia umbellata*), a charming little wanderer for sunny spots, and *Viola La Lorraine*, which, however powerful the sun may be, never ceases to bloom during the whole summer. *Crocus foliage* growing through a row of *Blue Bindweed*, having ripened, has now been removed. The *Bindweed* is rapidly showing itself, and a few blanks which have occurred during the winter have been made good with plants raised from seed sown last autumn. *Larkspurs*, hardy *Geraniums*, *Oriental Poppies*, etc., are now growing apace, and have needed support in the form of *Hazel boughs*. This is a better method of staking than using *Bamboo canes* and string, and looks more natural. *Lily of the Valley*, herbaceous *Phloxes*, *Funkias*, and various other subjects have received attention, and where possible the soil is broken up amongst the plants. A border containing *Christmas Roses*, edged with the little *Gypsophila prostrata alba*, has been forked up. A few plants of *Fuchsia fulgens*, which had been previously well hardened, have been planted out, and a quantity of *Cannas* in variety have been put out at each end of the *Lily tank*. Everything is well watered in as soon as the planting is finished. A large number of specimen plants in tubs and vases has been placed in their summer quarters. A group of *Salvia patens* has been put out among yellow *Roses* and mixed *Violas*. *Salvia splendens* has been given a place in the mixed border, and a few plants of *Salvia Greigi* have been put on a hot sunny corner.

Sussex.

SOUTHERN COUNTIES.

Late Muscats.—During the early part of the flowering period dull weather prevailed, which necessitated the use of fire heat, both to ensure suitable temperatures and to render the pollen potent. Brighter conditions afterwards allowed of the house being amply ventilated throughout the forenoon, and followed by a judicious employment of a camel-hair brush and a tapping of the rods several times daily, a good set, notwithstanding the fact that pollen of a free-setting variety was unavailable, has resulted, and the scissors are being brought into play more than is usually the case with Muscats. In thinning, great care is taken to get rid of seedless berries first. Then such as are of a pale colour, although they may swell, but do not keep pace with berries containing their full quota of seeds, are, whenever it is admissible to do so, cut out, as these, owing to their having but one or at the most two seeds in them, never swell to full size. Ofttimes a bunch when rid of all doubtful looking berries will look very thin, but it is surprising how by dint of good feeding and proper attention such will fill out, and by the time the berries have finished there is little, if any, spare space between them. Some exceptionally handsome pieces are having their shoulders suspended clear of the body of the bunches, but time and labour will not permit of anything further being done in this direction. On the completion of thinning the border will be mulched with short stable manure, the material being too scarce to allow of the removal of the greater part of the straw. As this gives off a certain amount of ammoniacal vapour when first introduced to the house, a chink of air must be left on night and day for a time to allow for its escape.

Early Muscats.—As the Grapes approach the colouring stage a final application of liquid manure will carry them through to the finish. That the colour may be as perfect as possible, the bunches where much shaded should be more freely exposed by drawing or tying the leaves on one side to admit of their experiencing a fuller share of the direct light. The colouring of the berries is taken as an indication that less moisture is now required and that a freer circulation of air, especially in the early part of the day, is necessary to ensure a good finish. The front ventilators now come into play, and, although closing them in the afternoon is in the earlier stages of colouring advisable, they may be left just a little open at first and afterwards wider as the Grapes near maturity. That the berries may attain a large size the close stopping of laterals should have strict attention.

Early vineries.—These, as soon as clear of their crops, should be ventilated to the fullest extent and the Vines well hosed now and again or washed with a garden engine. Whether necessary or not, so far as insects are concerned, this has a very refreshing effect on the foliage and prevents it from dying off prematurely.

Early planted-out Figs.—The fruits on these are now ripening, and syringing has

had for the time being to be discontinued. To prevent the footpath and border becoming too dry both are damped several times daily in bright weather. The fruits are not gathered until they are so ripe that they barely sustain their own weight. This is the only way to ensure full ripeness and impart that lusciousness which should be the distinguishing feature of forced Figs. A plentiful second crop will succeed the foregoing, and as soon as gathering ceases, syringing of the foliage and feeding from the surface will be resumed.

Kales.—The last of the latest crops have been cleared off, and the ground will, when circumstances permit, be dug with forks. This will leave the soil in a finer condition than would be the case with spade digging, and plants when set out will not be so adversely affected by hot weather should such at the time prevail.

Seed-sowing.—More Peas have been sown for late supply, while the moulding up and staking of advancing crops have been kept, so far, well in hand. With the exception of the earliest varieties, a great many of the seeds of which rotted in the ground, Peas are looking remarkably well, and promise an excellent yield. More French Beans have been sown and gaps made good in *Scarlet Runner rows*. A further sowing of *Globe Beet* for autumn use is now necessary. This saves having to begin using the long-rooted types before winter sets in. To keep up a regular succession of *Lettuces* of both the *Cos* and *Cabbage* types, fortnightly sowings are needed. Unless a cool border or partially shaded piece of ground is at liberty on which to plant them, thinning must now be ignored, hence the necessity for sowing frequently. Another sowing of *Short-Horn Carrots* will be made shortly.

A. W.

MIDLAND COUNTIES.

Early vineries containing ripe Grapes, which are being cut as required, should be ventilated rather freely, and during the day in the present warm weather abundance of air should be admitted both through the top and front ventilators. *Black Grapes* are apt to lose colour, and if they are to hang for a considerable time they will keep better if a light shading is placed on the roof. This is best done by stippling the glass with whiting. Damp the surface of the border and paths once on dull days, but more frequently in hot weather. During the day no fire heat is necessary; but it is advisable to keep a little heat in the pipes at night. Now that the fruit is finished, the sublateral growths may be allowed to extend. After all the fruit has been cut give the foliage a thorough syringing with clear water.

Mid-season Vines are afforded varying stimulants to encourage the development of large berries. Plenty of atmospheric moisture is now required, and also a free circulation of air, otherwise the foliage is apt to get scorched. The closing of the houses is now deferred until later in the afternoon, damping every available space. Later in the evening a little air is admitted by the top ventilators, allowing them to remain open all night, increasing the amount early in the morning to avoid scalding of the foliage and berries. Outside borders should be covered with a light mulching, preferably of long strawy litter. If the borders are in the least dry, give a thorough soaking of water before applying the mulch. If the natural drainage is good and the soil light, outside borders require liberal supplies of water in hot weather, and much benefit will be derived from a little artificial manure scattered over the border before the water is applied.

Strawberries.—Early varieties of Strawberries planted on a warm border look promising, and the fruits are swelling rapidly. It has been necessary to water the plants freely. The framework has been erected on which to place the nets. When the nets are merely spread over the beds many of the best berries are spoiled by birds. By using a framework the fruits are more easily gathered. Slugs and snails are great pests, and every precaution should be taken to protect the fruits. The supporting of the trusses of fruits on young plants should be done at once, and if extra fine berries are required the trusses should be well thinned. Stock plants put out last August for the special purpose of furnishing layers have been denuded of all their flowers, and will provide early runners. Soil in which Strawberries are to be planted should be trenched and manured the previous winter, and then cropped with early Potatoes.

Herbaceous borders.—Many of the plants in these are now in their full beauty. Coarse-growing subjects need to be restricted to their proper limits. Where the hoe can be used without injuring the plants, it is advantageous to stir the soil, as much for the purpose of conserving the moisture in the ground as for destroying weeds. This operation is best carried out on a dull day after rain.

Sweet Peas are making good progress, and the earliest plants are commencing to flower. It is necessary to train the leading shoots, so that they will grow in the right direction. The soil being very dry, watering has had to be done, and the ground about the plants mulched with stable manure. An occasional good dressing of soot will impart clearness and brilliancy to the flowers.

Summer-flowering Chrysanthemums are commencing to grow freely, and the soil requires hoeing at frequent intervals to keep it in good condition and clear of weeds. If slugs are troublesome, dust the plants occasionally with a little soot in the evening when dew is on them or after a shower. The soot will keep them clean and healthy, and is also a good stimulant. If the weather continues dry a light mulch will be beneficial and will save much watering. If the plants are strong and healthy they will branch freely naturally, rendering much stopping unnecessary. Place the stakes in position early, and secure the main stem firmly, using strong ties to loop up the other growths.

Dafodils that need division, either through having occupied the ground long enough or for purposes of extension should now be lifted for the first heavy rain experienced after the middle of June will cause them to commence growing, which should not be allowed before lifting. It is really much safer to lift even while the leaves still have some green left in them than to delay too long. After having been lifted they may be kept out of the ground for a week if other work is pressing, but it is much better to replant at once. In planting the bulbs, see that each rests firmly on the soil at its base, for bulbs that are "hung up" through making the hole too small at the bottom do not grow well.

Asparagus.—By the middle of the present month cutting will cease, taking care to leave growths as far as possible all over the bed, where practicable the beds should be given a thorough drenching of manure water, and in exposed positions the stronger growths will need support.

Leeks.—Early-planted Leeks should be watered frequently with liquid manure, and the soil between the plants stirred with a Dutch hoe to promote free growth. Those raised for the main crop are now ready for planting out. The ground having been trenched and well manured early in the year, it only requires to be forked over before drawing the drills at 18 inches apart and 3 inches to 4 inches in depth, planting the Leeks at 1 foot apart, using a garden dibber. Only a small quantity of soil should be allowed to fall among the roots, the remainder being afterwards worked in with the hoe, so that nothing may retard the swelling of the stems. Leeks are gross feeders, and therefore derive great benefit from frequent applications of weak liquid manure.

Winter Greens.—Many of these will be planted in their permanent quarters at the first opportunity. Every bit of ground available is utilised at this season, and in some cases it is necessary to plant between other crops, such as Peas, Beans, and Potatoes. In all cases sufficient space must be allowed for the plants to develop properly.

Potatoes are generally sufficiently advanced to complete the earthing up, but before commencing make sure that the surface of the soil is thoroughly freed from weeds. If extra fine tubers are required for any special purpose, the growths should be thinned to two or three of the strongest shoots. This is easily accomplished by placing the feet near the plant and drawing the weakest growths out with the hand.

Lettuces are sown frequently on a border somewhat sheltered from strong sunshine. These now succeed better if sown thinly where the plants may develop without disturbing them than if transplanted. The plants require liberal supplies of water during dry weather so that they may grow away without a check.

Endive.—A small sowing of Batavian Endive will be made now to afford supplies during the autumn, sowing the seeds in a somewhat shaded situation, and transplanting as soon as the seedlings are large enough to handle.

F. W. GALLOP.

SCOTLAND.

Planting out.—The filling of flower beds and borders with their summer occupants was begun in the course of the week. To some extent there is this year a curtailment in this respect. Much use is being made of plants which are easily raised, and, withal, showy. Antirrhinums are being used to a considerable extent. Each bed or group of beds is filled with plants of a decided colour—for example, crimson, white, pink, and orange varieties being planted. These are all of the intermediate type, and make neat, bushy plants, which fill up well, and give a good display over a prolonged period. Pentstemons, too, are being freely used, and, as has been previously indicated, "The Gem" varieties are preferred for planting out. Beds of *Salvia* *Pride of Zurich* are always bright and attractive in late summer and throughout the autumn, and several beds have been filled with single-flowered *Begonias*. A border will be devoted to yellow *Begonias*, while some use is being made of *Salvia* *patens*, *Ageratum*, *Lupins*, and *Brachycome iberidifolia* (the *Swan River Daisy*) in beds given over to blue flowers. The only edging plants used during the present year are *Lobelia* and *Alyssum* *miniaturum*, and their use is strictly limited. Ten-week *Stocks*, *Asters* (single and double), *Tufted Pansies*, *Marigolds*, *Sweet Geraniums*, *Calceolarias* (in limited numbers), and, in fact, the usual run of bedding-out plants will find places. At the time of writing, the weather is not unfavourable for this work.

Vegetable garden.—In the early part of the week, the soil having become surface dry, some arrears of work among vegetables were brought up. More Peas were moulded up and staked, and another 50 yards row was sown. Two sorts were used for this purpose—namely, *The Duchess* and *Alderman*—each variety occupying 25 yards. These two Peas form an invaluable succession when sown on the same date, both are of practically the same height, of robust growth, and carry heavy crops of well-filled large pods. Former sowings of these Peas are well advanced, and will shortly be in bloom. A return will now be made to early-maturing varieties in the remaining sowings—*The Pilot* and *Gradus* being preferred. More reliance is, however, placed on the former, for while *Gradus* is an excellent Pea, in some years it hardly justifies its inclusion. A line of *Broad Beans* was sown at the same time, the variety being *Harlington Windsor*. More *French Beans* went in, *Negro Longpod* being used at this time, and a line of *Veitch's Climbing French Bean* was sown on the same date. This and similar Beans, being very prolific, have been substituted for *Scarlet Runner Beans*, which are not in favour. A further line or two of *Climbing French Beans* will be sown shortly, the pods of which are used for bottling and preserving. More *Spinach*, *Turnips*, and *Lettuces* were sown.

Asparagus has received a good dressing of concentrated fertiliser, and this will be repeated from time to time during the growing season. At present the produce is closely cut, and the beds are being kept free from weeds as far as possible.

Potatoes.—Moulding up having been completed in the case of the earliest Potatoes, the next breadth has been forked up, and they will be moulded in the course of next week. Late varieties just breaking through the soil have been hoed through in order to keep seedling weeds in check.

Brassicas.—Successional lines of *Cauliflowers* were planted during the week, including *Early Giant*, *Eclipse*, and *Walcheren*. A few further lines of *Sprouts* and *Savoys* were also got out; but the main plantings will be deferred for a few weeks. Meantime, in order that no delay may take place at planting time, shallow trenches are being prepared for the reception of the plants.

Hardy-plant borders grow increasingly attractive. There is always something requiring attention among hardy plants, and to keep them free from weeds, if possible, ought to be the care of the grower. Formerly we used to hoe and rake these borders at frequent intervals, but last year the hoe only was used. It was found that if hoeing was tidily done the use of the rake could be dispensed with, and the same course will be followed throughout the present season.

The woodland.—The usual occasional look round the woodland was given during the week, in order that ties, stakes, etc., of young or recently planted trees might be seen to. The display at present is, perhaps, the best afforded by the woodland throughout the year. *Narcissi* and *Primroses* have gone, but their place is supplied by myriads of *Wood Hyacinths*, colonies of *London Pride*, large patches of *Star of Bethlehem*, *Pimpernel*, *Forget-me-not*, and of the double and single forms of *Saxifraga granulata*. The shades represented among the *Wood Hyacinths* range from white, through pink and purple, to various shades of blue. In addition, *Broom* is in full bloom, and all round the *Gorse* (*Whins*) is striking. *Azaleas*, *Lilacs*, *Laburnums*, and *Rhododendrons* are in excellent form. While looking round it was noticed that some large colonies of *Montbretias* which were naturalised some years ago are again coming away very strongly, as are some pieces of *Rosa* *Daisy* and of the more vigorous *Michaelmas Daisies* which have been put out in different positions from time to time.

Hydrangea paniculata.—In the case of this useful flowering shrub, the usual annual top-dressing was given in the course of the week. Some of these pieces are of great size, and never fail to flower freely. Planted in rich, deep, and rather peaty soil, they do not appear to require any further treatment than the removal of the flower-trusses when they cease to be attractive, and the yearly dressing of well-decayed manure and leaf-mould in mixture referred to. The same remarks may be taken as applying to hardy *Fuchsias*. Differing, however, from the *Hydrangea*, *Fuchsias* succeed in almost any kind of soil and in any exposure. They grow so freely that, perhaps, on that account one is at times apt to underestimate their value in the garden and in the shrubbery.

W. McGURROG.

Balmie Gardens, Kirkcudbright.

Trial of autumn-sown Onions at Wisley.
—The Royal Horticultural Society will carry out a trial of autumn-sown Onions at Wisley during the ensuing season. Seeds for trial (one packet of each variety) should be sent so as to reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey, from whom the necessary entry forms (one for each variety) may be obtained, on or before Monday, June 19th, 1916.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Destroying Nettles (*A. M. M.*).—Next to clearing out the roots of Nettles, the best way is to have the tops cut off hard with a hoe so fast as they appear through the soil. No perennial weeds can long withstand this treatment.

Roses in poor condition (*M. de C.*).—From what you say as to the position of the roses, the cause of the falling of the leaves is quite evident. The plants are dry at the roots, and if you give them a thorough soaking of water you will find, we think, that they will improve. You ought also to syringe them every evening as there are traces of red-spider on the leaves due to the dryness of the soil.

Iris *diseased* (*Miss Wilson*).—Your Irises are suffering from a fungoid disease common to the Iris. You ought to have moved the plants to fresh quarters directly you noted signs of the disease. Cut off all the diseased parts, and plant any that are not affected in this way. You should do this at once or as soon as flowering is over. Your plants have evidently been in the same position for some years. Irises should be divided and given fresh quarters at least every third year, as the soil gets impoverished, thus causing disease and failure.

FRUIT.

Growing Peach-tree in tub (*W. E. Woolley*).—Yes; a Peach-tree grown in a tub of good diameter and depth, such as may be obtained by cutting a paraffin barrel in half, and trained on the back wall of a house of the dimensions stated should succeed. The heating of the house during the months mentioned would, provided a temperature of 45 degs. to 50 degs. was not exceeded by these means, prove beneficial, and when the tree is sufficiently established to begin bearing it would, of course, place the flowers beyond the harmful effects of frost and render a crop more certain. We have had little or no experience in the heating of greenhouses with oil as fuel. It is the fumes arising from the combustion of the latter which are detrimental to the health of plants. If these can be kept from entering the house there would be nothing to fear. On the whole, we think you would be well advised to put down a cheap form of portable boiler with piping attached, as you would find such an apparatus perfectly safe, efficient, and far less costly in the end.

VEGETABLES.

Bottling green Peas (*Lady Winifred Lowry-Corry*).—Green Peas for bottling should be quite young and also of one size. Put them into wide-mouthed bottles with a pinch of salt on the top. Stand the bottles up to their necks in a large pot of water, which stand over a fire and boil slowly. So soon as the Peas seem to be soft, take the bottles out, cork them up, seal them over, and keep them in a dry, cool place. Bottling of green Peas is best done by someone who has intimate knowledge of the business, as a slight mistake may lead to failure.

Spraying Potatoes (*Chas. A. Ledward*).—The proper proportions of the sulphate of copper and lime solution, commonly called Bordeaux mixture, are 1 lb. of each. Tie the sulphate, which is bluestone, in a coarse piece of canvas, and put it into a wooden tub which will hold some 10 gallons. Put in 2 gallons of boiling water on the sulphate, and let it dissolve during the night. Also in a pail dissolve the lime, which should be fresh, and when clear add the water to that in the tub. Still further, dissolve in hot water 1 lb. of common treacle, and add that also. Then fill up the tub. The solution should be applied about the middle of July, with a second application three weeks later. It must be applied in the form of spray from a knapsack-sprayer, or by the aid of a spraying syringe. It is best applied in the evening.

SHORT REPLIES.

H. F. W.—You may cut down the *Lilacs* as you suggest, but by so doing you will sacrifice the bloom in the coming year. Seeing you have such handsome plants, we should advise you to leave them alone.—*Drury White*.—1. Certainly; but make sure that you give a thorough soaking. Dribbles are of no use. The evening is the best time to water. 2. No. 3. Yes; in the early spring. 4. Yes; you may do it in the early autumn. Of course, if you do not object to the untidy appearance of the lawn, you may top-dress now, the watering washing the goodness of the said top-dressing down to the roots. 5. Better without. 6. No. 7. Cut it every week, using the machine without the box, the short Grass helping to minimise the power of the sun. 8. No. We do not reply to queries by post, and are always ready through our pages to help those in any difficulty.

DESIGN IN PLANTING.

Who is to help? I believe the best results can only be got by the owner who knows and loves his ground. The greatest evil is the stereotyped plan, the evil results of which are evident on all sides. But the man must love the work and know one tree from the other, and feel that his pictures can only come from constant thought as to the ground itself. Lessons? Yes, from Nature mainly. A few days in one of the valleys in the Tyrol or any beautiful mountain land will tell more than many books, also pictures of the great landscape painters like Corot, Daubigny, Constable, and R. Wilson when free of the conventions of his day. The breadth, air, forms, foreground, and values that interest painters may teach us much. The atmosphere of Corot, skies of Diaz, water of Daubigny, and Nature's trees, landscape, and atmosphere should teach us much. It is ours to make such use of them as will give us better pictures than ever were painted. One wants the spade of the forester and the eye of the artist. Stereotyped plans are of no use. The lie of the ground must be studied in somewhat the way of the good leader of soldiers, and there is also the quality of the soil to be thought of, as soil useless for rich cultivation may give us fine tree effects. With hardy trees in the landscape, views, air, and distances also must be studied, not only in the place but from it to the neighbourhood. If rides essential to woodland are planned at first it will be a gain and simplify the protection of the young trees in early years. There is no organised profession to help. Anyone may call himself a landscape gardener; a navy who has some experience of walk and road making, a jobbing gardener, and others without any training may offer to do the work.

But how are we to know a landscape gardener? By this sign among others—that he will study the ground thoroughly first and bring no plan in his pocket. Office plans are poor substitutes for the thing itself, but the custom of plans on paper is so fixed that it is not easy to get this truth accepted. There can be no true work in landscape save by one who knows trees by heart, and there is no royal road to that knowledge save by life study.

The relationship of nurserymen to garden design is a delicate one. A nursery-

man's business is a wholly different one, and a useful and honourable one, and if he does his work well he has not the time to act as a designer of gardens. And in his case where is the control which should be exercised in all extensive work? W. R.

NOTES OF THE WEEK.

Sophora vicifolia.—We do not make enough of these Pea-flowered shrubs. The above-named is a graceful bush, with blue and white flowers. It is quite hardy and apparently easy to grow. It was introduced from China some fifteen or more years ago. From Kew.

Mr. Ernest Markham, for some time past the writer of the lists of hardy shrubs and plants flowering each week, and also of the "Work of the Week" among them, has now been called away from us for the Army. His good work will, we hope, be continued by a writer in a different county. Our gardens will suffer much from gardeners having gone to the war.

A dwarf rock Woodruff.—This seems of slight value when seen in dots or pots, but allowed to spread into spreading carpets it is quite pretty, and in that way can be best grown on a rock garden reasonably made. Many rockeries are made more to show off the stones than for the good of the plants, and there is no room on them to group a rock plant in any natural way. From the Pyrenees.

Primula denticulata cashmiriana.—The greatest measure of success with this is attained in a border with an easterly, but sheltered, exposure. The soil is heavy, moist, and deep, and loses the sun in mid-summer as early as 3 p.m., so that it is, generally speaking, quite cool. In this border the plants thrive amazingly and increase very rapidly, so much so as to be a source of wonder to those whose conditions are, perhaps, not quite so favourable.—W. McG., *Balmæ*.

Hybrid Poppies.—About thirty years ago several hybrids between *Papaver orientale* and *P. atlanticum* appeared here, and between *P. orientale* and *P. rupifragum*. I divided some of these in the early spring of last year and replanted in very good soil. The quantity of flowers on these hybrids and the brightness of the colour this season are remarkable. Perhaps the *rupifragum* hybrid is the brightest of all. I believe the same hybrid Poppies appeared in Mr. Carrington Ley's garden at

the same time as they did here.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed*.

Heracleum pyrenaicum.—The Latin names of these Giant Parsnips are many, but one very often sees the coarsest of them all grown under different names, and it is quite a relief to find one distinct from the others. This one has in the great head of flower a rosy effusion which should make it a very good wild garden plant. Being a Pyrenean plant it must be quite hardy.

Erodium trichomanefolium.—These pretty Geranium-like plants of the southern rocks are never made good use of in the rock garden even. Lately, at Kew, I saw a rosy-coloured one, a very pretty tufty thing. The new and sensible ideas about moraines and avoiding rich soils in rock gardens should help their culture well, even the most delicate of them. They are very happy on retaining walls, and some flower a long time. They deserve a better place than they usually get.—W.

A good combination.—*Viola cornuta* and the old white Pink, planted alternately, make a really good mixture. The pale blue of *V. cornuta* contrasts well with the greyish-white foliage and the pure white flowers of the Pinks. Blooming simultaneously, and over a long period, such a mixture can be recommended to those who admire combinations for early summer display. Both, of course, are so easily increased that the trouble incurred in working up a stock is infinitesimal, and the best display is obtained from plants which have been a few years established.—Kirk.

Begonia corallina.—Like others of the older Begonias, *B. corallina* does not now seem to be so popular as was formerly the case. Easily propagated from cuttings, young plants grow rapidly and are invaluable for furnishing trellises or roofs in warm greenhouses. *B. corallina* succeeds best when planted out, but fairly good results may be obtained when it is grown in large pots in a compost consisting of peat or good leaf-mould and loam in equal parts, with a free admixture of coarse sand and, if possible, a few fairly large pieces of broken sandstone. The flowers are of a bright coral-red, and a well-furnished trellis covered with bloom is a sight worth seeing. The late Mr. Jeffrey, at St. Mary's Isle Gardens, grew this fine Begonia very well, but he insisted that, to do it justice, it required the

heat of the stove. My experience is that it does equally well in a warm greenhouse, and that in such a house the display is prolonged over a greater period.—W. MCGUFFOG, *Balmæ*.

Abelia floribunda.—These always interesting plants are seldom rightly used in gardens, except in the extreme south. This one was in flower on the first day of June at Kew, and very handsome too, but evidently very tender and in need of the protection of an old brick wall there. It shows that the valley cold does not kill the plant and that it deserves to be grown wherever there are warm soils and walls.

Rhododendron Mrs. Wm. Agnew.—This lovely kind deserves to be more frequently seen in gardens. In a collection of these popular shrubs the pink flowers, shading to deep rose towards the edges of the petals, the upper petal blotched with yellow, stand out conspicuously. The trusses of bloom average 6 inches across and deep, and are freely produced all over the plant. Another advantage of this variety is that the flowers retain their colour and are not so easily damaged by rain as are the more floppy varieties. For grouping it is unsurpassed by any other variety of this colour. A very poor substitute is often sent out, therefore care should be taken to obtain the true form.—E. M.

Economy in the garden.—A recent article on this subject from the pen of Mr. Hudson (p. 214) contains several valuable hints, and one which is the reverse. I quote his words: "With both Peas and Runner Beans, what is needed is more seed, and so let the rows be as close again." Anything from Mr. Hudson is worthy of attention, but surely he is on the wrong track here. Good crops of these two particular subjects cannot possibly be expected if crowding—one of the greatest mistakes in vegetable growing—be practised, more especially if, as is recommended, the seeds are sown thickly. What benefit can be obtained by following this advice—even if it does favour the seedsman—and wherein consists the economy of buying more seeds of Peas and of Runner Beans than are actually necessary? With the other remarks no fault can be found.—KIRK.

New Zealand Satin Flower (*Libertia formosa*).—This is one of the choicest herbaceous plants for late May and early June. It belongs to the Iris family, though, unlike many of that genus, its leaves are evergreen. Once established, this plant sends up numerous spikes—a yard in length—from which issue bunches of pure, waxy-white, three-petalled flowers with yellow stamens. It is a first-rate plant for the herbaceous border, the rock garden, or as a group in the foreground of shrubs, where the soil is warm and friable, and fully exposed to sunshine, under which conditions it increases freely. With me a group of this *Libertia* is very happy at the base of some old Pine-trees, where it flowers freely annually. The long, stiff, and somewhat branching spikes of bloom are excellent for indoor decoration.—E. M.

Tulip Golden Crown.—Although an old Tulip, this holds its own, and deserves still more extended cultivation, especially where Tulips are permanently planted. I know gardens where it has been left undisturbed for many years without any signs of deterioration. Possibly the flowers may be a little smaller when the bulbs become rather crowded, but it is amazing the amount of bloom given by groups of this Tulip, even when closer together than the best cultural practice would warrant. Few Tulips would stand

the hardships this one has to undergo in certain circumstances. Almost every day I pass a front garden on a dusty road where many plants of Tulip Golden Crown are all aglow in their season. The lot of the plants may seem an unhappy one, as daily in dry weather leaves and flowers alike are thickly coated with dust; yet they bloom bravely as they have done for years. It is a Tulip I grow largely in different positions. Its flowers are of a bright yellow, gradually becoming faintly margined with crimson. This margin extends, and eventually the entire flower becomes flushed with bright crimson. I have grown this Tulip for fully thirty years, and my bulbs have only had their natural rest in the soil.—S. A.

Achillea ptarmica The Pearl.—The difficulty experienced by "H. F. S." (p. 282) is by no means uncommon in some districts with *A. ptarmica*. "H. F. S.," perhaps, suffers from excessive rainfall during winter, and, if so, the roots of the plants put out in autumn probably never make a real start, and this, combined with the profuse bloom in summer, no doubt leads to the collapse of the plants during the ensuing winter. At Dunalastair Castle, in Perthshire, the same difficulty is found with *A. ptarmica*, and the reason suggested is that given above. On the other hand, in these gardens the plant runs through Box-edgings, invading the stools of other plants, and getting, generally, out of hand. I would suggest that "H. F. S.," instead of cutting the stems after flowering ceases, should, for the first season, prevent the plants flowering at all. This might, possibly, have a good effect, and the variety is so useful in its way that a little experimenting would not be altogether time thrown away.—W. MCG., *Balmæ*.

[In a London suburban garden, in a light, rich, warm soil, this plant, though so valuable for providing cut flowers in plenty, is a perfect weed, over-running all the other plants in its vicinity. Every season I have to curtail it, and even when seemingly cleared out it comes up in the most unlikely places. Still, with all its faults, I would not care to be without a piece of it in the garden.—T.]

The English Bluebell (*Scilla festalis*).—It is pleasant to read the appreciative notes by G. H. Raynor, in your issue of June 3 (p. 270), on the English Blue Bell. I have found all the varieties mentioned as occurring among the wild plants except the buff one found by his friend. The varieties offered by Mr. Van Tubergen, most of which I grow, are very beautiful, and when in groups of separate colours are full of charm on a carpet of Grass, or with a mossy wall covered with Ferns and trailing plants in the background. The varieties of *Scilla festalis* are much more graceful than those of *S. campanulata*, the Spanish Squill, which look stiff and ungraceful. My finest variety of *S. festalis* is one I received many years ago from Holland as *S. patula alba*. It has larger and more arching spikes of flowers than any other variety I possess, and they are of a beautiful pure white. I have many seedlings in my garden, the colours varying from the ordinary blue, through lilac, to deep blue, and various shades of pink, in addition to whites. The blues predominate, even among seedlings from the white or pink, but a group or two of mixed seedlings generally meets with the admiration of those who see these flowers. I have a curious variety with narrow, constricted flowers. I got it many years ago from the late Mr. P. Neill-Fraser, of Rockville, Murrayfield, Edinburgh. Its

flowers are white but of a creamy hue, and the form is more curious than beautiful. It was given me under the name of *S. stricta*. There is no *Scilla* under that name in the "Index Kewensis," and I am of opinion that it is simply a seminal variety of *S. festalis*. This is borne out by the fact that self-sown seedlings are of the normal form of *Scilla festalis*, without any trace of the constricted shape of *Scilla stricta*. It is interesting, although a little disappointing, to find that seedlings from the named varieties rarely equal the parents.—S. ARNOTT.

Primula pubescens alba.—"N. L." (page 299) does not seem to know that there is another plant in existence—a white, too—under this name. Kerner, the great authority on the European Primulas, found *P. pubescens* growing wild along with *P. Aretotis*. He found, too, that both were hybrids of *P. Auricula* and *P. hirsuta*, but that *P. Aretotis* had not as much of *P. Auricula* in its composition. He gave the name *P. Aretotis alba* to the plant generally known as *P. nivalis*. The above information I had from the late Robert Lindsay, of Edinburgh, who was a very safe authority in such matters. I had a curious confirmation of his correctness when, several years ago, I found a large batch of *P. nivalis* in a continental nursery under the name of *P. Aretotis alba*. I have known the true *P. pubescens alba* for thirty years. It is a taller plant with tubular, drooping flowers and clammy at the base of the leaves. Farrer mentions finding this plant in both a Yorkshire garden and also in Devonshire. My original plants came from Aberdeen. "N. L." may be interested to know that there are several other whites in these small "Auriculas" as *P. marginata alba*, *P. helvetica alba*, *P. decora alba*, and White Pearl raised by Mr. Lindsay.—J. STORMONTH, *Kirkbride, Carlisle*.

Wood Lilies (*Trillium grandiflorum*).—Seldom have these been so effective as they are this year, their luxuriant foliage and delicately-coloured flowers borne on stout stems almost 2 feet in length when the plants are in good health. A few groups were made here three years ago beneath large Magnolias. Large rings were thrown out and the clayey soil disposed of, its place being taken by a mixture of peat, loam, sand, and rotted leaves. In this the plants have done remarkably well, as what originally was a single crown has now developed into four and five crowns, and the plants are increasing in vigour year by year. The crinkled flowers, each 5 inches across, vary in colour from the purest white to deep rose, just the delicate shades so much sought after for decoration, to which use they are admirably adapted. The slight shade of the Magnolias appears to suit them, and the effect when the sun is just broken by the shade of the thin branches is very pleasing. I cannot imagine these charming perennial plants happier even in their native habitat, North America. The threefold arrangement of both flowers and leaves has given them the name, Trinity Flowers, and other names. All who can devote a suitable space, however small, to them, should grow these charming plants.—E. M.

—The fairest flower of the last days of May to me is the Wood Lily of the North American woods. In the gentle shade of a colony of Magnolias I find it does well. For years I lost it in Azalea beds. Well grown, it well deserves its name of Wood Lily. Peat and leafy soil seem to help it much. The natural conditions of things are always worth looking into.—W.

TREES AND SHRUBS.

HARDY HEATHS IN STORM.

I WAS pleased, the other day, to see the Heaths taking the place they deserve at Kew, and rejoiced to hear from Mr. Bean that there are two wild species in Spain which we have not got. It is a very pleasant excuse for a man to go to Spain and find these things. The two shown in our illustration are the beautiful Southern Heath and the Portuguese Heath in the background. Both have passed through the winter and harsh, wet spring and flowered beautifully all the time. It would be very interesting if we could get new varieties of these in their native countries as we have of our own native Heaths; also if there are Heaths in Asia Minor and other countries such as Serbia. The charm of growing them is, that rightly used they

flowers, but these rarely ripen here. It should be planted in good, loamy soil in a sunny position, and it is advisable to provide shelter from cold winds. Propagation is usually effected by layers or seeds. In America the fruit is sometimes eaten, and the plant is of interest as being a close and, perhaps, the hardiest relative of the Anonas.—D.

HARDY BAMBOOS.

IN the Bamboos we have a family of evergreens which for beauty and gracefulness cannot be excelled by any other plants. From North India, China, and Japan quite a large number of species and varieties has been introduced, while one, *Arundinaria macrosperma* var. *tecta*, comes from the United States. The majority have proved quite hardy if sheltered from bleak north-east winds, these being far more injurious than sharp frosts. In selecting a

look at home, apparently benefiting from the moist condition of the air in such places. The Bamboo is valuable for home woodlands, especially where the trees are summer-leaving, and, when used in this way, spreading in many cases to an alarming extent and providing excellent shelter for game. Rabbits do not touch them, although they will burrow beneath and lie among the accumulated bottom, which in the case of *Arundinaria palmata* is like a number of layers of crossed wire, difficult even for a dog to penetrate. For bordering woodland rides or furnishing dells and pond-sides nothing is more effective.

They are divided into three groups—*Arundinaria*, *Bambusa*, and *Phyllostachys*, from which selections—for even the smallest gardens—can easily be made. Many of the dwarf forms have a variety of uses and are great favourites.

PLANTING.—The best time for this work

The Southern and Portuguese Heaths after winter storms.

give us lovely gardens in winter and all through the spring. W.

The Papaw (*Asimina triloba*).—Although introduced many years ago, this interesting and curious small tree or shrub is uncommon and but rarely met with. There are, however, several good bushes in the Kew collection, and one or more occurs in the garden of H.R.H. the Duchess of Albany at Claremont. It is a native of the south-eastern United States, where it forms a large bush or small tree and is known by the common name of Papaw, although a very different plant from the Papaw or Papau of Tropical America (*Carica Papaya*), a tree widely cultivated in tropical countries for its fruit. *A. triloba* is distinguished by its oblong, prominently-veined leaves, and by its curious, triangular, purple flowers, which are produced singly from the leaf-axils and are each about 2 inches across. Clusters of curious, sausage-like fruits succeed the

SITE FOR BAMBOOS it is necessary to use discretion. It has often been observed that plants exposed to cold winds and frosts lose their freshness long before those enjoying a certain amount of shelter. They will grow fully exposed and make handsome specimens in isolated positions, but shelter is necessary to see them at their best, and where possible a little shade is an advantage. Few evergreen plants or shrubs show to such advantage during the winter, especially during wet and stormy weather. They are interesting when bent to the ground by a fall of snow, the whole plant often being left without a single erect cane. This does not injure them, and with the advent of more favourable conditions they again display their great beauty.

The ideal spot is undoubtedly in groups along the sides of a small stream, where they receive abundance of moisture during the late summer and autumn. Indeed, when seen in association with water they

is the early part of May, just as the new leaves appear, but in private gardens planting at this season is not always convenient, owing to pressure of other important work. Where this is so I would recommend early autumn planting, which I have invariably found to be most satisfactory, even with very large specimens. I have planted them at intervals all through the winter, from early October to May, with excellent results. I remember one nice collection of these plants arriving from the nursery in January, the balls of soil frozen right through. The ground, of a sandy and clayey nature, having been previously prepared, they were planted the same day, plenty of good leaf-soil being added as the work proceeded. The growth made by these plants during the following season reached a height of 10 feet, while the second season the magnificent canes gave rise to comment. A good heavy loam suits them best, and where the soil is light I would add some clay and

plenty of leaf-soil. Care should be taken that newly-moved specimens do not become dry at the roots until active growth is visible, otherwise they take much longer to become established, and occasionally the best canes shed their leaves. These, with care, break into leaf again and quickly recover if kept supplied with moisture. Our climate is quite different from that in their own country, where the season of heat is also the season of deluging rains, conditions admirably suited to their rapid development, whereas our summers are often accompanied by periods of drought, followed by late autumn and winter rains, which leave the ground cold and sodden, coming, too, when most of the species have matured their season's growth. Apparently they quite enjoy even these conditions, forming under suitable conditions magnificent specimens.

These hardy Bamboos are admirably suited for growing in large tubs and vases for the decoration of rooms, porches, and terraces, their light, graceful forms appealing strongly to those responsible for this class of work. Where used for this purpose the shelter of a cool greenhouse is necessary during frosty weather, otherwise if the roots are allowed to become frozen right through for any length of time the probability is that they will not survive such treatment. When visiting a neighbouring garden last year I was astonished to see Bamboos growing in what appeared to me an old quarry. Protected on two sides by large deciduous trees and evergreens it presented a perfect mass of tropical luxuriance. Here were Bamboos of such proportions as I have never before seen, revelling in the rich, leafy soil; in some cases they were growing in beds edged with large stones, while others were planted on the steep sides with little pathways—over which they had long since formed an arch—winding among them. This must be an ideal retreat during hot spells, as it was quite possible for a person to walk about beneath them in comfort. This spot must be very moist in winter, although I saw no actual stream, and, being low, the position was sheltered from cutting winds, which, in my opinion, is of the greatest importance.

A selection of these elegant subjects should include the following:—

ARUNDINARIA ANCEPS.—A beautiful tall-growing species often reaching 18 feet in height. Of a spreading character, it quickly forms a large clump by underground suckers.

A. AURICOMA is a dwarf kind from 2 feet to 3 feet high, the rich golden foliage becoming intensified as the season advances. I have used this brilliant plant as an edging to beds of tall shrubs, in which position it is most effective, especially so when associated with the purple Barberry, *Ribes sanguineum*, and *Buddleias*. Planted in full sunshine and cut to the ground annually (in March) is the most satisfactory way of treating this kind, as in this way there is an absence of old and shabby leaves, and the young, fresh growths are seen to great advantage. In warm soils it spreads rapidly and is very suitable for small gardens.

A. FASTUOSA.—A fine species which forms a stately column, its lofty, plumed canes presenting a richness excelled by no other kind. As an isolated specimen it is one of the best.

A. NITIDA.—A favourite wherever grown. It is one of the hardiest of Bamboos, spreading rapidly under favourable conditions.

A. SIMONI is a vigorous, tall-growing kind, reaching 18 feet and more with age. It requires plenty of space and is seen at its best when half-developed.

A. JAPONICA.—This well-known form makes a dense mass of shining evergreen foliage and will grow almost anywhere. For grouping beneath and near summer-leaving trees or bordering woodland rides it is most suitable. I saw this accommodating plant a few years ago growing over the roof of an old cave in the Deepdene Gardens, Dorking, where there were scarcely more than 6 inches of soil, which at times must have been very dry, but such a thicket had it become that a dog could scarcely have got through it.

A. PALMATA.—A handsome plant reaching about 5 feet in height, this should be planted only where it can spread freely. As undergrowth in woodland or wild garden, or as a large colony near the water-side, it is seen to advantage, the large leaves, each over a foot in length and 3 inches across, being very striking, especially after rain.

A. PYGMAEA is the smallest Bamboo in cultivation. As a groundwork to small trees or large shrubs it is excellent, carpeting the whole surface with its soft, fresh, green leaves. It should not be planted near choice subjects.

PHYLLOSTACHYS.

In this group we find the noblest forms of the whole family.

P. AUREA.—This is not one of the tallest, generally reaching from 12 feet to 14 feet, with an equal spread; nor does it ramble, but it is much sought after for isolated specimens on lawns. Its pale green leaves borne on rather erect, greenish-yellow stems are pleasing, and although so popular as a single plant, it is one of the most effective when boldly grouped.

P. CASTILLONIS is a slender form which reaches from 8 feet to 10 feet in height. Under favourable circumstances this is very fine, its long leaves being usually striped with gold in their early stages, while the canes are quite golden and remain so to maturity. I have found this Bamboo rather tender in a young state, but it seems quite able to take care of itself when well established.

P. HENONIS.—A well-developed plant of this Bamboo is unsurpassed by any other kind. Reaching from 12 feet to 14 feet or more in height, this kind is not easily mistaken, while its distinctness stamps it as one of the most precious of Bamboos.

P. MITIS is the tallest of the group, reaching in its own country (Japan) 60 feet in height, while some examples have attained 20 feet in this country. It is remarkable for its immense canes, often 2 inches thick, and its rapid growth. A well-sheltered position should be chosen for this, as the wind has a disastrous effect on the newly-developing canes. In Japan the young shoots are cooked and eaten as a vegetable. A curious and distinct feature of this form is the rough, gritty-like surface of the canes.

P. NIGRA reaches, under generous treatment, 20 feet in height. Its lofty black stems and shining green foliage are its great attraction. This is a splendid form either for grouping or as an isolated specimen in medium-sized gardens and one which keeps within bounds.

P. QUILLOI.—The feature of this is its thick, highly-polished canes and large leaves, the latter about the largest of this group. It reaches about 18 feet high in this country. I have noticed that in an adult state this striking form becomes a little naked towards the base, which shows up its thick canes to advantage, adding to, rather than detracting from, its stately beauty.

P. VIRIDI-GLAUCESCENS is a free-growing and very distinct Bamboo reaching 18 feet or more in height, throwing out its long,

slender, branching growths in every direction, and forming a huge, spreading, and arching mass. I consider this one of the most beautiful Bamboos in cultivation. It increases rapidly, therefore plenty of space should be provided at the time of planting.

P. KUMASACA is a gem for small gardens. Its curious zigzagged stems and glossy dark green leaves, arranged in fours, have always appealed to me. It is a unique and charming little plant easy to grow, and, unlike most of the dwarf kinds, stays at home. It is suitable for low, moist spots in the rock garden and as a foreground to the taller species.

E. MARKHAM.

CRATEGO-MESPILUS.

This composite name is used for three hardy trees which are hybrids between the Hawthorn (*Crataegus monogyna*) and the Medlar (*Mespilus germanica*). Two of the three trees, *C.-M. Asnieresii* and *C.-M. Dardari*, are of peculiar interest, inasmuch as they are graft hybrids and behave in a similar manner to *Laburnum Adami*, a better-known graft hybrid between the *Laburnum* (*L. vulgare*) and the *Purple Broom* (*Cytisus purpureus*). The two *Cratago-Mespilus* forms referred to occurred after a *Mespilus* had been grafted upon a Thorn. Both grow into bush-headed trees, and bear sometimes two and sometimes three distinct types of flowers, leaves, and fruits. The majority of the flowers are in clusters, but are larger than those of the Hawthorn. There are, however, others which closely resemble those of Hawthorn, and others again that are borne singly and are similar in size to those of the Medlar. Similar remarks apply to the fruits. Apart from their scientific interest, they are very beautiful flowering trees, blooming as freely as any Thorn. The third hybrid is *C.-M. grandiflora*, which has been called *Mespilus Smithi*, *Pyrus lobata*, etc. This is considered a natural hybrid between the Thorn and the Medlar, and was originally found wild in France. It forms a fine tree of medium height with a dense, wide-spreading head, bearing distinct oval leaves and small clusters of white flowers, each one about 1 inch across. All are easily grown, thriving in ordinary loamy soil and are well worth planting where interesting and out-of-the-way trees are encouraged. The full history of these graft-hybrids is to be found in "Trees Hardy in the British Isles," by W. J. Bean, where also fuller descriptions of the trees may be found. D.

NOTES AND REPLIES.

Escallonia Philippiana.—This, which is at its best usually about midsummer, is a very beautiful and distinct *Escallonia*. Furthermore, it is the hardiest member of the genus. It forms a sturdy-growing yet graceful-habited shrub that will reach a height of 6 feet or more. The flowers, which are borne on the ends of short twigs, are pure white, and when at their best so numerous that the entire specimen is quite a mass of that tint. A notable feature is the fact that the blossoms are totally without the tube common to many *Escallonias*, and also that the plant is summer-leaving. It is a native of Valdivia. A very desirable hybrid between *E. Philippiana* and *E. punctata*, *E. Langleyensis*, has come very much to the front within recent years. This flowers in June. The first blooms opened with me on the last day of May. They are of a bright rosy-carmine colour, and very numerous. In the open ground this will form a large, spreading bush as much as 8 feet in height.

It is just the thing for furnishing a wall or fence, as, if the main branches are secured to the support and the secondary ones allowed to dispose themselves at will, a charming effect is produced. This Escallonia is often spoken of as being evergreen or sub-evergreen in character, but, with me, in the south-west of London, it loses practically all its leaves during the winter. The new ones come out with a rush, so that, once started, the plant is soon a mass of foliage. This Escallonia can be readily struck from cuttings of the half-ripened shoots put into a close frame till rooted.—K. R. W.

Escallonia macrantha.—For the south and south-west counties this is a useful evergreen. Its partiality for sea air is noticeable in many southern gardens, where it is met with as a fine bush or hedge in exposed places; in fact, it might well be used more widely than at present as a hedge plant, for it is far more interesting than many now used for the purpose, and, where it succeeds, might well take the place of Privet. On Mr. Dorrien-Smith's bulb farm at Tresco it is used as

bare bank of poor soil has to be covered this is the best method to adopt. It can be used as a companion to the common Broom for clothing rubbish-heaps at collieries and railway embankments, in which places it can be sometimes made to act as a nurse for seedling trees.—W. K.

PLANTS AND FLOWERS.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

OXALIS ENNEAPHYLLA.

This beautiful plant, from the Falkland Islands, is among the choicest of subjects for the rock garden. Well-grown specimens are not so often met with as one would like, as in many gardens it is regarded as somewhat capricious. The rootstock is in the form of an elongated, scaly bulb, and the foliage is extremely pretty. The flowers, pure, glistening white with a greenish tinge at the base of the petals, are carried upon slender stems similar to those supporting the leaves. The flowers appear about the

temperature from 20 degs. to 50 degs. and a summer one of 45 degs. to 65 degs.

This tells us at once that *Oxalis enneaphylla* will not be at home in a sun-baked position. Yet it is most sensitive to the sun's influence; it shuts up at sundown, and is shy about opening on grey, sunless days. A cool position, shaded from the sun during the middle of the day in well-drained stony soil, should suit it.

It flourishes and increases well here on an open ledge where it gets the morning sun, but is partially shaded by rocks for the greater part of the day, in soil containing plenty of crushed granite and small stones. It can be propagated without much difficulty, just as it comes into growth in the spring.—J. HARPER SCAIFE in *Irish Gardening*.

NOTES AND REPLIES.

Arenaria montana.—I have seen this in many gardens, but nowhere have I met with more flourishing plants than in Mr. Galbraith's delightful garden at Terregles, by Dumfries. Here, *Arenaria montana* is planted by the rockwork edging of a slightly elevated bed, and it is this season a mass of white flowers, hardly a leaf being visible among the thousands of blooms. For covering a stone edging to an elevated bed it is delightful, and it is equally fine when hanging down over a rock face. In some places it is a little difficult to establish, but, once settled down, its only defect is its tendency to encroach upon its neighbours.—S. ARNOTT.

Eriogonum umbellatum.—A patch of this in a sloping pocket of the rock garden has given me pleasure all through the winter, the tufts of leathery, evergreen foliage tinged with bronze being very attractive. It is now in blossom, but the flowers are not specially pleasing, and I should not grow it for the sake of the blossoms. The flowers are in flat heads, and of a very pale, almost greenish, yellow. I give it a little lime in the soil, which seems to suit it well, as it spreads fairly rapidly, and the prostrate stems layer themselves so that it can easily be increased. It is of neat habit, and, though growing freely, does not ramp.—W. O.

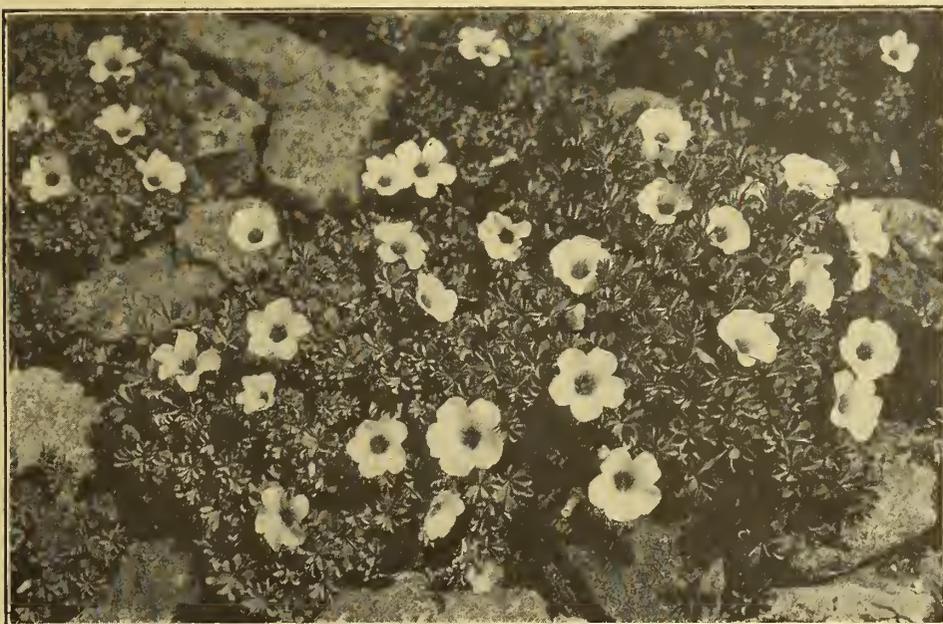

Geranium Robertianum album.—The white form of the wild Herb Robert is much dwarfer in habit and more compact than the type, and is very pretty growing in the chinks of a retaining wall. Though only biennial, it seeds freely, and never sprawls about like the common form. I grow both on a retaining wall, as I think both are very pretty, though the common pink type seeds so freely that it takes up more room than I can spare it.—W. O.

Campanula barbata.—This does very well in a moraine made of crushed brick with a little soil and lime, improving year by year, established clumps throwing up a great number of flower-spikes. The flowers remind one very much of those of a miniature Canterbury Bell, and are of a soft luminous pale-blue colour. It is easily raised from seed, but unless grown in the moraine seems to be of only biennial duration.

Valeriana supina.—This is a pretty little plant of compact habit, growing only a few inches high, having small, flattish heads of tiny flowers of a pale pink. It looks very neat in the rock garden, and a good patch of it is very pleasing. It likes a soil with a little lime in it and a flat, sunny pocket suits it well.

Stachys corsica.—This pretty little carpenter seems happy in any open soil, and blossoms with great freedom over a long period. It is of very neat habit, and the curious flattish flowers, of a pinkish-white colour, nestle closely among the foliage. It quickly spreads, and can readily be increased by division.

Morisia hypogæa.—In spite of the wet winter this has come through very well in my London garden, and at the beginning of May two little clumps of it were covered with their delicate flowers of a pure rich butter-yellow. Many people seem to lose it in the winter, but it does not appear at all difficult to suit in my garden, where it is grown in a retaining wall in warm, porous soil.—N. L.

Oxalis enneaphylla in the gardens at Lilford Hall, Oundle, Northants.

a wind-break between bulb fields, and there forms fine hedges 5 feet or 6 feet high. When allowed to grow freely it forms a fine bush up to 10 feet or more in height and as much through. The rose-red flowers are borne freely during summer and are very effective. Where it cannot be grown as a bush in the open ground it can be used with good effect as a wall shrub, particularly if it is not too severely pruned.—D.

The Hairy Broom (*Genista pilosa*).—Found wild in some parts of the British Isles, this dwarf Broom is an acquisition for gardens, particularly where a low covering is required for an exposed bank of poor soil or a ground covering for a bed of tall bushes. Growing from 18 inches to 2 feet high, it spreads over a wide space, and continues in good condition for many years without any attention in the way of pruning or top-dressing. The golden flowers are borne very freely from the middle of May until the middle of June, an established group being a perfect sheet of gold for the greater part of that time. Seeds are produced freely, from which plants, which after a year or two in the nursery quarters can be moved to permanent places, are easily raised. Seeds can also be sown in the positions the plants are to occupy, and when a

middle of May and are effective for a month. This plant succeeds with me in a cool, sandy soil, in a position exposed to a fair amount of sun. A cool rooting medium and abundant sunshine are the principal requirements for the successful cultivation of this charming plant.

F. W. GALLOP.

Lilford Hall, Oundle.

—Opinions will differ as to which is the most beautiful of the rock garden plants, though there is little doubt but that *Oxalis enneaphylla* would easily get a place among the first half-dozen. It is a fascinating and extremely beautiful plant with crinkled glaucous grey leaves, in themselves very attractive. The flower, somewhat like a *Convolvulus* in form, but pearly-white, with a splash of purple at the base of the cup, must be seen to be properly appreciated. It is not only unlike anything else in the rock garden, it is almost without a rival in its loveliness. Yet it is hardly an alpine, as it comes from the Falkland Islands, a bleak inclement country with a rainfall greater than the average for this country, and a winter

VEGETABLES.

LATE PEAS.

PREPARATION for the sowing of these should now be made. Deeply-worked soil is essential for this crop if good results are looked for, but on soils which dry out quickly a little extra trouble in the way of preparing the drills beforehand pays in the long run. This consists in digging out the soil where the rows are to stand—which, by the way, should not be closer together than 12 feet—a good spit in depth, and, after breaking up the bottom with a fork, putting in a layer of rotten manure some 3 inches thick. Then return the soil, breaking it down to a fine condition when doing so, and place the surplus on either side of the drills, so that the latter will lie, as it were, in a kind of basin and act as a conservator of water, whether applied artificially or when it falls in the form of rain. Mulchings can then be easily applied, should the nature of the season demand it, later on. The seed should be sown thinly, so that the plants have ample space for development, as the majority of late varieties are of a robust growth.

Of varieties there are several which, if sown at the same time, will afford a good succession or render a supply more certain than if one sort alone is selected. *Ne Plus Ultra*, in its improved form, is on some soils hard to beat. *Autoerat* enjoys a good reputation, and in some gardens succeeds better than the first-named variety. *Gladstone* is another reliable variety which in some seasons continues to yield until cut down by frost. *Continuity* and *Late Queen* are also worth growing where the demand is large and Peas are required as late as they can be had. To succeed the main crop sorts and to come into bearing before any of the foregoing, *Eureka* stands unrivalled. G. P. K.

SECURING THE STEMS OF ASPARAGUS.

I WISH you would give us an article upon the value of supporting the long shoots of *Asparagus* with the seeds attached. Recent winds have blown down a good many of mine, and, labour being so scarce, one wonders if the snapping of them is really any great damage to the beds.—J. D. THORBURN.

[This is not practised so often as it should be, and yet it should be looked upon as one of the most important details connected with its culture. One might go into numbers of gardens during the summer and find the *Asparagus* quarters somewhat neglected, the tops bending over. Even if not partially broken through, they are in such a condition that they cannot perform their proper functions—viz., storing the roots with nutriment for another season's crop. Considering that *Asparagus* is one of the most important of vegetables, it is surprising that it should so often be left to take care of itself, and yet when the season comes round the crop is eagerly looked for; in fact, when vegetables are scarce it has to prove a veritable sheet anchor. Being truly herbaceous, it is all the more desirable that the growths be well cared for. We have known seasons when the stems would have been quite free from injury until the summer was far advanced, or, indeed, well into autumn, before any violent storms have occurred, but one can never tell what may happen, and it is always best to be well prepared.]

The process of staking is not at all difficult, and the time it takes is hardly worth mentioning. Where the crowns are very strong and planted some distance apart, these should have a stake placed to them

individually, taking care that the stakes are not thrust into the centres of the crowns. In other cases stout stakes may be placed at each end of the lines, and a few others intermediate down the rows, or according to the distance, these being for the support of long and slender rods, and to which the stems must be tied. Another advantage, besides protecting from wind-waving, is that by being tied upright, direct sunshine and light reach the crowns. Not only established plants, but seedlings also should be carefully staked.]

NOTES AND REPLIES.

Leeks—sowing versus planting out.—I have given both ways many trials side by side, and am convinced, when wanted for ordinary kitchen use, that sowing where to grow is the better way. I sow the seed early in March on land that has been trenched, working plenty of manure into the bottom spit. Before sowing, the soil is made very firm. A sprinkling of poultry-manure and soot is thrown over the seeds, this giving them a start. When large enough to handle they are thinned to 4 inches apart. During the growing season these receive two or three dressings of soot or manure-water. In the early winter the soil is drawn up to them in a ridge 8 inches high. This blanches them and protects them. The plants are about the thickness of a large broom-handle. If Leeks are wanted for exhibition then the seed must be sown early in heat, planting out in trenches, and giving generous treatment.

GARDEN FOOD.

NOTES AND REPLIES.

Helpful hints to health and happiness.

—Mrs. Earle has written a little book with the above title. It is full of her ideas of food reform and kindred subjects, and much good sense and good cooking, too. It costs 2d., and is published by Simpkin, Marshall, and Co., and may be had from all booksellers. We quote the following:—

A great obstacle to the change of diet is the family doctor, and I wish to warn people that if they consult their doctor no change of diet will be tried. Doctors and surgeons are good kind men on their own lines, and devoted to their profession as long as it means curing illness by drugs and operations, but a little reflection teaches that the members of a learned profession are naturally the very persons least disposed to innovation upon the practices which custom and prescription have rendered sacred in their eyes. The state which is called disease, or being very ill, belongs to the doctors and surgeons, the hospitals and nurses; but keeping well and curing small ailments, both our own and our children's, depend on ourselves.

The Newtown Pippin.—An article in a recent number of *GARDENING ILLUSTRATED* on the above has brought us a few lines from the Rev. H. S. Clubb, a minister of the New Church, Philadelphia, and President of the Vegetarian Society of America. Mr. Clubb believes that it was the *Newtown Pippin* that made the importation of Apples to England a possibility. In spite of the success of this Apple, he tells us it is seldom seen in American markets. Mr. Clubb had a good deal to do in his earlier years with the development of *Apple-growing* in the States. After the war between North and South (in which he was

twice wounded) he settled in Michigan and began to grow fruit. His success with Apples was so great that he was invited to visit other States and advise how to proceed. Thus he did great service for America and for fruit lovers.

WHITE VEGETABLE SOUPS.

MANY housewives consider that white soups are more trouble to make than the ordinary kinds. This is a mistake. A white soup takes less time to prepare; in fact, many of them, if made from cold boiled vegetables, might come under the heading of "fifteen minutes" soups, they are cooked so quickly. A good clear vegetable stock may be used. The water in which Celery, Haricot Beans, Salsafy, Potatoes, Cauliflower, or Parsnips have been boiled should always be saved for this purpose. To make a good

POTATO SOUP take four large Potatoes (or the equivalent in cold boiled Potatoes), boil, and mash them finely. Melt a tablespoonful of butter in a clean saucepan, add a tablespoonful of flour, and fry for three minutes. Chop a medium-sized English Onion, which add to the mixture in the pan and cook for another three minutes. Do not allow the contents of the pan to colour in the least degree. Finally, pour over the fried flour and Onion a pint of boiling water or clear, colourless vegetable stock. Flavour sufficiently with salt and pepper. Stir well and simmer until the whole is well blended and smooth. Mix the mashed Potatoes gradually into a pint of new milk, and add to the mixture in the saucepan. Simmer for ten minutes and serve with tiny squares of fried bread or toast in a separate dish. A tablespoonful of finely-chopped Parsley should be sprinkled on the top of the soup just before it is sent to table. A tablespoonful of good, rich cream improves this soup.

CAULIFLOWER SOUP is easily and quickly prepared, provided, of course, you have some cold Cauliflower at hand, otherwise time must be allowed for its cooking. Take a pint of water, one finely-chopped Onion, all the white parts of a Cauliflower, also chopped, salt and pepper to taste. Simmer the Cauliflower and Onion until quite tender, and add a tablespoonful of butter, a breakfastcupful of white bread-crumbs, and a pint of new milk. Bring the whole to a boil and simmer until the crumbs have pulped. This will take about ten minutes. Beat with a fork for a few seconds and pour into a tureen. Sprinkle a little chopped Parsley on top and serve at once. To vary this soup omit the Onion and sprinkle a tablespoonful of grated Parmesan cheese into the soup the instant it has been poured into the tureen.

The following, although not strictly a white soup, is made with milk and is very nourishing and good. Boil half a cupful of rice in just sufficient water to cook it. When tender rub it through a sieve and return to the saucepan with three breakfastcupfuls of milk, a tablespoonful of Onion-juice, salt and pepper to taste, and two cupfuls of Tomato purée made by boiling Tomatoes with a little water and rubbing them through a sieve. Simmer gently for three minutes, then add a dessertspoonful of flour rubbed into the same quantity of butter, and continue simmering the soup until the whole is smooth and well blended. If too thick add a little more milk. Serve with tiny squares of toasted bread. Nutmeg or mace can be added to the flavouring if this is liked, and the top can be garnished by sprinkling it with chopped Chives or Shallot tops. H. THORBURN-CLARKE.

OUTDOOR PLANTS.

GLOBE FLOWERS IN ROUGH GRASS.

GLOBE FLOWERS are handsome, hardy things, not often well done in gardens. Their blooming time is not very long, and their cultivation in flower gardens is not the best way. We want a piece of coarse Grass to put them into. The one shown here is just on the edge of a little plantation of shrubs, and the Grass is not mown. The plants begin to bloom well in that position, and give us a pleasure we never had when cultivating them as mixed border plants, though some kinds of Globe Flowers are well worthy of a place in borders. W.

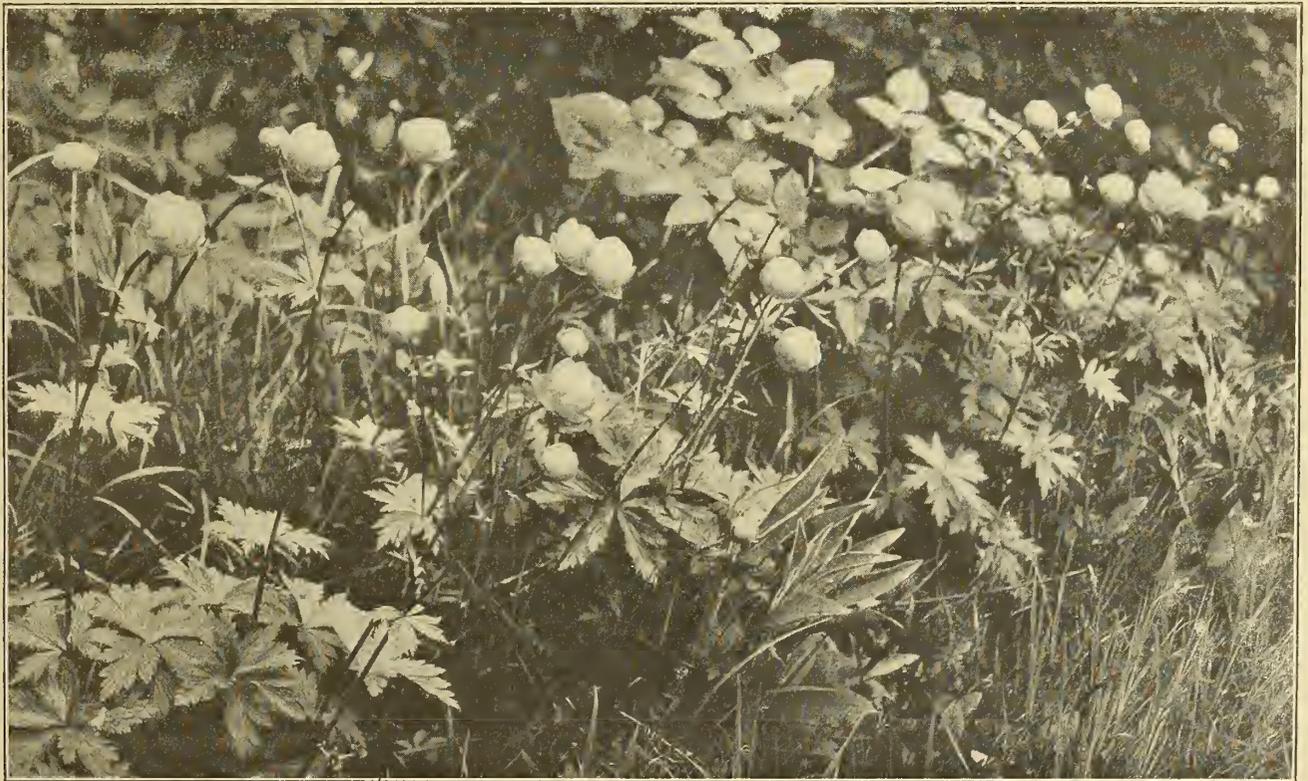

AMONG THE HARDY FLOWERS.

MONARDAS.—Is "Kirk" doing justice to *Monarda didyma* in his note on p. 286? There are several varieties, some of which are very fine and others very

permanent quarters about the following April. I have found that plants divided in autumn or spring are liable to suffer from the attacks of slugs. In light soils Pyrethrums are greatly benefited by cow-manure in the soil, as also by occasional soakings of weak liquid manure before they come into bloom.

SUN ROSES.—These are among the glories of the garden in June, and I do not wonder that they are appreciated by those who have long known them. I am gradually trying to increase the number in my garden by securing good varieties, and I have also raised some from seeds. I have not secured anything which is very new among the seedlings, but I have obtained quite a number of plants with a variety of colours and at a cheap rate. I found them no more difficult to raise than any other hardy perennial. I do not like the double varieties so well as the singles. My great objection to most of the doubles which I have met with is that their flowers

caterpillar in some clumps of *Iris sibirica*. I could not understand at first why the plants were not flourishing, until I investigated the matter carefully and found that in many cases the interior of the stems had been eaten away. The caterpillar responsible for the damage is the larva of *Apamea ophiogramma*, a smallish moth which at one time was reckoned somewhat of a rarity by collectors, but of late years has occurred pretty abundantly round London. The first sign of the caterpillar's presence is that the central leaf turns yellow, and the only thing to be done is to cut the whole shoot off close to the root, when the caterpillar will be found in the heart of the shoot and can be destroyed. In gardens it usually feeds on the stems of Ribbon Grass, where its presence can be detected in the same way, by the withering of the central leaf. It is getting quite a nuisance in my garden, and this year I found it had attacked a small clump of *Iris Tolmieana*. I wonder

Part of a group of Globe Flowers in the Grass.

poor, both in colour and in size of flower. A good deal also depends upon the soil, and it is just possible that in "Kirk's" garden it may not be of the kind liked by the Monardas. A good, rather moist soil I find suits the Monarda. The best variety is known as "Cambridge Scarlet," in which the flowers are large and of a rich scarlet.

PYRETHRUMS.—These are useful in the garden and also for cutting. The best time to divide them is, I find, as soon as they have finished flowering. My practice is to lift the plants which I wish to divide as soon as the bulk of the flowers is over, cutting them up with a sharp knife into almost single crowns, retaining, if I can, a bit of root on each of these. The pieces are then dibbled out into a bed made up of loam, leaf-soil, and a little sand. I make the soil firm, water frequently if the weather should be dry, which it often is at that time, and shade them slightly from strong sunshine for a few days. They rarely look back, and are put into their

are too heavy for the stalks and hang down. That bright scarlet one called Mrs. Earle is an exception, and there are, it appears, some sports from that variety with the same excellent habit. The advantage of the doubles is that they are not so evanescent, but the flowers are lumpy compared with the delightful blossoms of the single-flowered varieties. If *Helianthemum* are planted where the sun does not reach them too early in the day they can be had in bloom in the afternoon.

ANEMONE NARCISSIFLORA.—What a charming plant this is! It gives me little or no trouble and flowers every year. It is said to like a calcareous soil, but in my garden it does not get this, and is happy in ordinary loam. I have it in sun and shade, and my plants in both cases are doing well.

AN AMATEUR OF HARDY FLOWERS.

Caterpillars in *Iris* stems.—I have during the last year or two been a good deal troubled by a small stem-boring

if others have been troubled in the same way. I have also had it attack *Iris stylosa*.—N. L.

THE CORNFLOWERS.

Among the many things known familiarly as common flowers that help to beautify our gardens at this season, Cornflowers, both annual and perennial, take a front place, whether in small patches or massed on a large scale. In the latter the most satisfactory results are obtained when a little trouble has been taken in the selection alike in the way of height and colour. Blue is the predominating shade among the annuals, and so, for the sake of variety, one has to save some nice flowers among the clarets and also in the white, getting the latter as clear as possible, and avoiding the dull, dingy flowers. There is nothing at present to equal the exquisite whiteness of, for instance, some of the *Campanulas*, but careful selection effects great improvement. The dwarf strains of the annuals are pretty and useful, but if

not available, their places can be filled by the perennial *Centaurea montana* and its varieties in varying shades of blue, dull red, lilac, white, and sulphur, and these, being of dwarf habit, can be used occasionally among and in front of the taller annuals.

This system of gathering together the representatives of any particular family in groups gives very pleasing results, and might be extensively carried out where space permits, anything of indifferent quality being weeded out as better varieties come to the front. There is nothing much among the taller perennial *Centaureas* worth a place other than in the wild garden, except it may be *macrocephala*, which furnishes a colour not to be found in any of the annuals. A garden close by was very bright at this time last year with an association of blue *Cornflowers* and *Lilium candidum*, but this season the display is lacking, the whole of the Lilies having completely collapsed, not so much as a single spike of bloom. I suggested the advisability of clearing them out and substituting one of the new white varieties of *Lupinus polyphyllus*, which would be a very good companion for the *Cornflowers*. E. B. S.

Hardwick.

NOTES AND REPLIES.

Iberis Little Gem.—I fear I am repentant regarding *Iberis Little Gem*, which "J. S." criticises so unfavourably in your issue of June 10th (p. 282). It would be useful to know what your correspondent calls "a fair trial." In its small stages it does not show its real value, and nobody will ever claim for it the "vigour" of other hardy evergreen *Candytufts*. It is just in the latter point that the defect of the larger varieties is evident, except for those with large rock gardens or other places where strong-growing plants can be safely planted. *I. Little Gem* is a plant for many places where these stronger-growing *Iberises* cannot with advantage be utilised. It is not out of place in the smallest rock garden, and is thus a boon for the small garden. It is such a slow grower that it takes some time to reveal its true worth, and I know that an established plant here, which has been in its present position for a good number of years, has for some time never failed when in bloom to please even the most critical. I have seen others quite as good. I have handsome plants of the other evergreen *Candytufts* and think highly of them, but, given a fair chance, *Little Gem* deserves the fullest consideration from those who wish a neat *Iberis* of slow growth, unaggressive in its ways, and giving a plentiful supply of white flowers in its season. The failing of the other evergreen *Candytufts* is usually that of too rampant growth for many places. I have some masses of these 4 feet and 5 feet across, and do not wish to reduce their size, but *Little Gem* is a plant of a different kind, cultivated for merits which to me are undeniable when it is well established and thoroughly happy. Long experience has taught me that plants of little or no beauty in some places are of the highest charm in others. I have seen and also grown this *Iberis* where it was a disappointment for a few seasons, but where it afterwards displayed its true worth.—S. ARNOTT.

Thalictrum aquilegiaefolium.—This plant will soon be in bloom. I like it as well as any of the *Thalictrums*. The height is about 3 feet, and it usually blooms very freely in June and July. The flowers are creamy-white, and the foliage also is beautiful.—E. T. ELLIS, *Westwood, Ecclesall, Sheffield.*

CHRYSANTHEMUMS.

FINAL POTTING OF CHRYSANTHEMUMS.

CHRYSANTHEMUM-GROWERS will now be very busy attending to the final potting. Inexperienced growers very often think that older cultivators use very elaborate composts for this potting. An ideal compost is one which will for some time furnish all the nourishment—with clear water—that the plants require, then act as a good store-house for the liquid manure and artificial manures given, without becoming sour and water-logged. A good compost is fibrous loam which has been cut and stacked outside for about three months, two parts half-rotted leaf-soil and horse-manure, one part old mortar rubble and coarse silver sand. To the above add to each bushel of the combined parts a 3-inch potful of soot, bone-meal, and wood-ashes respectively. All the ingredients should be thoroughly mixed. I am not in favour of adding much artificial manure at this stage, as I think it is best not to force the growth, but to feed later on. Ten-inch pots may be used for the strong-growing varieties, but 8-inch ones are large enough for the others, except March and April rooted plants, which are generally confined to one stem and one bloom. These should be grown in 6½-inch and 7-inch pots. It is not the bulk of the drainage material, but the way in which it is arranged in the pots that ensures the free passage of the water. One hollow crock over the hole with a few small ones, with thin pieces of turf placed on them, will make good drainage. Both the pots and the crocks must be washed and used while they are perfectly dry. Examine the plants carefully. If the roots are numerous round the outside of the ball of soil, lose no time in getting the plants repotted. For this purpose the soil will be in just the right condition if the plants are watered about two hours before, but no watering must be done if the soil is moist. Each plant must be potted so that ample space will be left for a top-dressing and for watering. Make the compost in the bottom of the pot firm and even, and also that used for filling in between the pot and the ball of soil. No new soil must be placed on the old ball, neither must the latter be rammed down with the stick. Where new stakes are required they should be placed in the holes made by the smaller stakes, then damage to the roots is avoided.

If possible, the plants should be placed in their summer position when taken from the potting-bench, as early exposure to light, sunshine, and air is beneficial. The plants should be arranged in rows running due north and south, if this is convenient; and if there is a natural protection, about 20 yards away, against the south-west winds, so much the better. Specimen plants and late-flowering varieties, too, must have ample room in an open position, as the best results are obtained from gradually-matured wood. G. G.

Chrysanthemums planted in open ground.

—Last year reference was made to this plan in your pages, but no description how to proceed was given. It was merely stated market gardeners grew quantities so and lifted them in autumn. Please say how soil is prepared, how far apart to plant, if any stimulant is applied, when to lift into pots, and anything else desired? I grow only for conservatory and house decoration, and have all sorts, but more of what I see described as decorative and late varieties, and I wish to save heavy labour involved in potting on, watering, etc.—BRENTWOOD.

[Ground that has been prepared as for

other crops—that is, deeply dug and kept free from weeds—should do for planting out *Chrysanthemums*. Choose an open spot. In the matter of moisture the season will, of course, have a lot to do with it; but to be prepared for drought in the case of this thirsty subject it is well to plant in trenches slightly lower than the surface, so that when water is applied the roots of the plants get it. Rows 1 yard apart, and each plant 18 inches from its neighbour, should allow ample space for the strongest grower. The sorts, of course, vary in growth, but each should be staked and properly trained. The branches may be thinned at will, but the points of all should be allowed to proceed untouched. It is not safe to leave the plants in the ground after the first week in October, and at this time, whether placed in pots or planted into soil in glass-houses, one should be careful to note that the roots do not want for moisture. If the soil approaches dryness the plants cannot be lifted with good balls, and without this the flowering will not be satisfactory. It is not advisable to feed if the leaves be of good colour, as such practice would cause gross growth. When the flower-buds appear, assistance in this direction will be needed. When lifted in early autumn the plants should be kept close and shaded and sprinkled overhead for a few days. Afterwards they should be treated in the matter of air as those that have been grown in pots the whole summer. Later varieties, not perhaps showing buds by the time named, should be lifted then, because frost would harm them.]

INDOOR PLANTS.

NOTES AND REPLIES.

Feeding Pelargoniums.—I should much like to know the best stimulant to apply to *Zonals* specially to increase the size and quality of blooms. I have quantities of cow and horse manure, and lately have been using the former enclosed in a sack in a large can, adding water as the liquid is used up, but find little result. What do those who grow for exhibition use? My compost is five parts light turfy loam, one leaf, one manure, and one sand.—BRENTWOOD.

[Other conditions being satisfactory, you should find the manure used an aid to size and quality of bloom. One could not wish for a better stimulant than that from cow-manure. Those who grow for exhibition use sulphate of ammonia to put size and colour into the flowers; but, after all, the chief thing is strong and healthy plants. In such a compost as you describe your plants should be such. In the case of your *Zonals*, perhaps you have made the mistake of allowing the flower-trusses to develop from the time the plants were struck from cuttings. A good plan is to remove these until a plant has had time to produce a specimen of a bushy nature; then let it blossom. To enhance the size of trusses and pips, manure-water may be employed, and besides this it is well to pinch out the points of the shoots above the trusses of bloom.]

Greenhouse flowers from seeds.—At the recent Chelsea Show the value for greenhouse decoration of plants that can be raised from seeds was well exemplified. Some of our prominent seed merchants vied with each other in showing what a variety of plants can be obtained in this way. Among them may be mentioned *Gloxinias* of various colours, *Streptocarpis*, of which the same may be said, *Calceolarias*, especially those of the herbaceous section, though of other kinds the variety *Clibrani* was very conspicuous. *Schizanthuses* were freely represented, as

also were Petunias, Stocks, Primula obconica, and others. The date of the show is a very suitable time for Cinerarias, and they were, of course, very much in evidence. Some annual flowers usually regarded as outdoor subjects served to show their great value for greenhouse decoration when grown in pots. Among them may be noted Phlox Drummondii, Nemesias of sorts, different Clarkias, and Mignonette. The different hybrid Nicotianas were also seen to considerable advantage. The cheap rate at which seeds of the above-named can be obtained and their easy culture, combined with the fact that they are not long in attaining the flowering stage, are all points in their favour.—W. T.

FRUIT.

GOOSEBERRY WHINHAM'S INDUSTRY.

APART from its value when ripe, Whinham's Industry is a first-rate variety to grow for gathering green. Especially is it valuable where large quantities of small,

Part of a fruiting branch of Gooseberry Whinham's Industry.

green Gooseberries are required for bottling. Whinham's Industry is a very prolific variety, and is, in addition, a sure and consistent cropper. The berries, red in colour, when ripe are of a good size, and if not of the highest flavour are yet of very fair quality.

LATE VINES.

THESE are now in flower, therefore syringing has been discontinued, but as a too dry atmosphere is detrimental to setting at this time of year, damping of the foot-paths and the surface of the borders is practised as usual. With the exception of a few rods of Gros Colman, which are on Madresfield Court Black Muscat and Lady Downe's respectively, and do not set well without artificial aid, an occasional tapping of the rods suffices to disperse the pollen and ensure a good set. As soon as this is accomplished free ventilation in accordance with the weather will be indulged in, as it is not desirable from a labour point of view to hasten the swelling of the berries more than can be avoided, as a house of Muscats is now engaging attention in the way of thinning, and must be finished before a start is

made with the former. When this takes place Black Alicante and Gros Maroe will be thinned first, in consequence of the berries soon becoming wedged, and difficult to deal with if neglected for a few days. Stopping of snblateral growths and the final tying of laterals into place succeed the completion of pollination, and with a good soaking of tepid water the border will, for a few weeks, need no serious thought bestowed on it. The weather will now soon be warm enough to dispense with fire-heat, but on dull and wet days damping down must then be cautiously done, if not actually suspended, for the time being. Ventilating by the front lights should also be eschewed until the berries have finished stoning or an attack of mildew may result. The proper manipulation of the top ventilators will suffice to maintain the temperature at the proper figures until that period is reached.

A. W.

PEACH TREES IN UNHEATED HOUSE.

I should be obliged if you will inform me as to the treatment of Peach-trees grown under

to allow for the extension of the trees. If there is not space for the two basal shoots to be laid in, then reduce them to one, giving that on the upper side the preference. When properly regulated this young wood should stand about 4 inches apart all over the trees. This then will serve as a guide and enable you to judge how best to deal with the growths now present on the tree, only instead of removing them with the finger and thumb, as when disbudding, recourse will, we surmise, have to be had to the use of a knife to effect their removal, so that neither bark nor wood is injured.

As regards the fruit, this, as soon as it has "stoned"—i.e., when the seed vessels have become quite hard—must be thinned down to safe limits. One fruit to every square foot of trellising covered by the trees is the proper number to leave. In carrying out this thinning give as far as possible those fruits the preference which are situated on the upper part of the wood or branches, as they will, on account of being fully exposed to the sun, be more highly coloured and of richer flavour than those which ripen in semi-shade. It is very important that the border does not get dry and the trees suffer from want of water.]

NOTES AND REPLIES.

Grease-banding fruit.—Early last autumn I put paper bands covered with grease round all my Apple and Pear trees, but I had a lot of trouble, chiefly in renewing the grease. I am now told that bands of cotton wool make the best bands against the codlin-moth, etc., and I am anxious to know how they are to be applied, and if they can be bought in any convenient form. Do these cotton-wool bands do more than the hay bands or the canvas sacking bands, which, to quote from one of your articles, were "to provide a convenient place for the caterpillars to become chrysalides."—F. W.

Raspberry canes.—I notice that "A. W.," page 291, hoes off his surplus canes at the ground level. I venture to think that this is a mistake. These hoed-off suckers will inevitably break away from underground eyes, and a perfect jungle will result. I speak from experience. It is much better, and equally as quickly done, to pull such suckers out by the roots. This, if done when the soil is moist, inflicts only trifling damage to the roots of the canes left.—KIRK.

The weather of April.—In the current number of *Symons's Meteorological Magazine* it is stated that "the distribution of rainfall compared with the normal, showed in general a deficiency over the southern half of England, most pronounced in the Devon-Cornwall peninsula, where many stations had only a quarter of the average, and an excess elsewhere. The greatest rainfall, 10 inches or more, fell in the normally rainy areas in Kerry, Carmarthen, and West Inverness, and the least, about half an inch, on the south coast from the Isle of Wight to Torquay. Heavy daily falls were uncommon, the greatest being 2.47 inches at Seathwaite on the 17th. Heavy local thunderstorm rain in east Yorkshire on the 20th yielded quantities slightly under 2 inches, and in the south-east of Ireland on the 24th and 25th falls of about the same amount were recorded during the passage of a shallow depression secondary to that of the main disturbance in the north-west. In the Thames Valley the distribution of rainfall was remarkably uniform. A little more than 1½ inches fell along the North Downs and that part of Suffolk on the Thames Valley map. Less than an inch fell to the north of the Thames estuary and over a large portion of the south-western areas.

glass without heat. I have two, Hale's Early and Royal George. They are putting out a large amount of growth. Should they be pruned now—that is, some of the growth taken out? The fruit is about the size of Walnuts. The trees are about eight years old. The Royal George has about fifty fruits on it; Hale's Early only two. Royal George is a year or two older. The trees are in very good heart, having been lifted and root-pruned two years ago. They did well last year.—P. PRIESTLY.

[With regard to the first part of your query, the number of young growths should be reduced so that enough and no more are left to furnish the trees with bearing wood in all parts for another season. This should have been done directly after the fruit had set. When performed at this period this is known as "disbudding," and consists in pulling off in a tentative manner to start with all shoots pointing in an outward direction on the bearing or flowering wood. This done, a start should then be made with those situated on the sides of the bearing wood, gradually reducing the number of these in the same way until but two are left at the base and one at the tips to draw the sap for the nourishment of the fruit, and

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM JUNE 8TH.—*Clematises* (in various colours), *Shrubby Spiræas* (various), *False Heath* (*Fabiana imbricata*), *Wistarias*, *Rhododendrons* (in great variety), *Ghent Azaleas* (in variety), *Bush and Climbing Honeysuckles*, *Laburnums*, *Kalmias*, *Broom* (various colours), *American and Native Thorns*, *Pyrus Malus* (in variety), *Olearia macrodonta*, *Berberis* (several kinds), *Rhaphiolepis ovata*, *Jasmines*, *Polygonum baldschuanicum*, *Lilacs* (various), *Deutzias*, *Rubus* (several species), *Philadelphus* (in variety), *Roses* (many species and varieties), *Snouberry*, *Stranvesia undulata*, *Rock and Sun Roses* (in great variety), *Viburnums*, *Kerrias*, *Diervillas* (in various colours), *Magnolias* (in variety), *Robinia Kelseyi*, *Honeysuckles*, *Ribes speciosum*, *Calycanthus floridus*, *Ericas*, *Bruckenthalia spiculifolia*, *Grevillea rosmarinifolia*, *Crimson Chestnut*, *Anemones* (in variety), *Heucheras*, *Geums* (in variety), *Forgloves* (various colours), *Libertia formosa*, *Alliums*, *Crambe cordifolia*, *Homeria collina*, *Camassias* (various), *Geraniums*, *Rodgersia podophylla*, *Everlasting Peas*, *Sweet William*, *Torch Lily*, *Linarias*, *Paenies*, *Thymus Serpyllum* (in various colours), *Gladiolus byzantinus*, *Meconopsis* (several), *Achilleas*, *Moss and encrusted Rock-foils*, *Tufted Pansies* (in great variety), *Gazania splendens*, *Mule Pinks* (several kinds), *Maiden Pinks*, *Helichrysums*, *Gysophilas*, *Tropæolum polyphyllum*, *Canary Creeper*, *Silene sylvestris*, *Anchusas* (in variety), *Trea Lupins*, *L. polyphyllus* (in several varieties), *Thrift* (*Armeria*), *Columbines*, *Muehlenbeckia complexa nona*, *Irises*, *Wood Lilies*, *Thalictrums*, *Lithospermums* (in variety), *Sweet Peas*, *Nepeta Mussini*, *Myosotis*, *Opium Oriental*, *Field and Iceland Poppies*, *Globe-flowers*, *Tradescantia virginica*, *Flax* (in variety), *Alpine Speedwells* (several kinds), *Edelweiss*, *Candytuft*, *Antennarias*, *Oralis* (various), *Erigeron Asa Grey*, *Dictamnus Fracinnella* (in variety), *Phlomis Samia*, *Larkspurs*, *Day Lilies*, *Eremuri*, *Campanulas*, *Betonica grandiflora robusta*, *Asphodelus luteus*, *Gerbera Jamesoni*, *Monroe's Mallow*, *Nierembergia frutescens*, *English and Spanish Irises*, *Hypericum reptans*, *Coronilla cappadocica*, *C. minima*, *Androsace lanuginosa*, *Ethionemas*, *Sopponoria ocymoides*, *Epilobium pedunculare*, *Cheiranthus linifolius*, *Nymphaeas* (several), *Rheum palmatum*.

WORK OF THE WEEK.—Climbing plants are now growing freely, and unless given a certain amount of training quickly become a tangled mass, thereby losing half their charm. Several Clematises are already in bloom, and others are rapidly approaching the flowering stage. *Polygonum baldschuanicum* should be planted at the foot of trees where it can wander and trail freely. A good deal of planting has been done, and the weather being showery, newly-planted things have gone away freely. An edging of Bellflowers has been made good, and a few plants of *Nolana atriplicifolia* were used to furnish the end of a Rose bed. *Viola Moseley Perfection*, a beautiful deep-yellow self, has been planted among Roses, and a number of *Cynoglossum amabile* has been put out at the base of Sweet Pea columns, while various kinds of *Nemesias* have been used for a similar purpose. Blue Gem is excellent for carpeting Rose beds, and has been used extensively. A few plants of *Cherry Pie* (*Heliotrope*) raised from seed have been planted out on a warm, sunny border, and others will be added as the plants become sufficiently advanced. These seedling plants are very satisfactory, and grow much stronger and taller than plants raised from cuttings, moreover they produce larger trusses of bloom. *Monroe's Mallow* has been planted across the corner of a bed, and a further supply of *Blue Bindweed* has been planted beneath thinly-disposed *Fuchsias*. Having a nice lot of seedlings of this plant to spare, they have been used as a carpet to a bed of yellow Roses. Weeds are a constant source of trouble when coming up in flagstone paths. We intend to try weed-killer along these narrow crevices later on, though hitherto fear of its reaching the occupants of the beds has prevented its use. The decaying flowers are removed from *Rhododendrons*, and as the

various Rock Cresses pass out of bloom the seed-vessels are removed and where necessary the plants cut hard back. A long line of the Pasque-flower has been relieved of its seed-vessels, which if allowed to mature rob the plants of much vigour. A few *Felicia abyssinica* have been planted in the foreground of the mixed border, and *Gazania splendens* forms a carpet to a mixed bed of African Lilies (*Agapanthus*). *Verbena purpurea* has been used to form an edging to a bed of Roses and Sword Lilies, and a batch of *Blue Nemesia* has been planted to form a carpet to the Wand-flower (*Dierama pulcherrima*). A further batch of *Desfontainea spinosa* (raised from cuttings) has been put out in the nursery border. E. M.

Sussex.

SOUTHERN COUNTIES.

Wall fruit trees.—Peaches and Nectarines require a final look over to relieve them of surplus shoots which have hitherto escaped attention, as no more of these than is absolutely necessary should be retained. Some amount of tying and tacking is now required, as the earlier and the straighter the shoots are trained in and secured to the face of the wall the better for the trees. Apricots also need to have all breast wood again pinched back to three and four leaves to form the foundation of fruiting spurs. Young shoots for the filling in of vacancies and extension purposes should also be neatly fastened back to the wall. Sweet Cherries are best pinched back while the wood is in a succulent condition, as it can then be stopped without the aid of a knife, and risk of gumming afterwards is averted. Plums may have the breast wood left a trifle longer than for the last-named, and all extensions and shoots needed for furnishing blank spaces, and so on, should be trained out in good time. Pears must be treated in a similar manner—only the pieces of wood left with the intention either of forming new or the further furnishing of existing spurs should be left somewhat shorter, or, say, three to four leaves instead of five. The wood in Morello Cherries requires a judicious thinning—in fact, no more should be reserved than there is room for when it is fastened back to the wall. The inveterate enemy of the Morello (black-fly) is much in evidence this season, but it quickly succumbs when well wetted with a solution of Quassia extract. This takes greater effect when the young shoots are in a rigid position, so that an excellent time to give the trees a thorough dressing is directly the tying and tacking in of young growths have been completed. Where time for the tacking in can hardly be spared, the young growths, both in this and previously mentioned instances, can be securely held in position with portions of the young shoots of Privet or Hazel. Armed with a quantity of either, cut to convenient lengths, a great many shoots can be quickly secured in position by placing the former in front of the shoot which has to be trained in and passing either end behind the adjacent main or subsidiary branches. The only disadvantage is that the young wood cannot be trained out so straight as when ties or nails and shreds are employed. A quantity of growth has already been made on espaliers, and stopping must, therefore, be done to prevent any further undue shading of the main leaves and fruit. Pears, Apples, and Cherries may, therefore, have their surplus growths stopped at the fourth, and Plums at the fifth leaf respectively. Extensions, both vertically and diagonally, should be tied into the training wires intact.

Strawberries have set well, and promise an abundant crop, but the fruit will be much later in ripening than usual. Birds, particularly blackbirds and thrushes, being so numerous, the beds have had to be securely netted, and that the gathering may be the more conveniently carried out the nets are stretched over a framework of poles raised some little distance above ground level. With regard to root moisture, matters are as yet in quite a satisfactory condition.

Bush fruit quarters.—Weeds are proving a great nuisance, and much time is being devoted to a vigorous use of the hoe to keep any-

thing like a semblance of tidiness. Red Currants are making a quantity of strong growth, which will ere long, with the exception of the leader, be shortened back. Another application of the hoe is required to rid the Raspberry plantation of further surplus growths now pushing through the soil. The shoots pushed up around the stools of autumn-fruiting kinds should now be thinned, leaving the best as a matter of course, and so situated that when eventually trained to the wires they will be about 9 inches apart. Summer-fruiting Raspberries will be netted over at the first convenient opportunity.

Seakale.—The young growths on Seakale intended for forcing, as well as those on crowns growing in permanent positions for late supply must now be thinned. Two shoots may be left in the former case on good strong roots, and one only on those of a less robust nature. With regard to the latter, the roots of which vary in size from one inch to 3 inches in diameter, from three to four shoots may be left, as these invariably grow vigorously and make very robust crowns ere autumn arrives. The removal of surplus shoots greatly accelerates growth, and to stimulate it, sprinklings of salt, guano, or any nitrogenous manure may from time to time—preferably during showery weather—be given with beneficial results.

Rhubarb.—With a more than ordinary demand to meet, the crowns are, as a result, in a rather exhausted condition. To enable them to recuperate, feeding with manure either in a solid or liquid state is necessary.

Chicory.—The plants in the last sown drills should be thinned to 9 inches apart, and the soil well hoed through afterwards.

Maincrop Celery.—This will be planted out shortly in the trenches prepared for it. To avoid exposing the roots to the air longer than is necessary, one man should remain in the trench and set the plants out as fast as they are carried to him. If this is followed up by a good soaking of water the plants experience little or no ill-effects from the removal. Watering for some time to come must have regular attention, as a check to growth has to be carefully avoided.

Amboldt's Bouvardia.—The general stock of this will now be planted out. Except in dull weather, the plants will be syringed twice daily, and the requirements of the roots in the way of water regularly attended to. After the roots get a grip of the surrounding soil and new growth is put forth, weak liquid-manure applied now and again encourages the production of a quantity of vigorous shoots, all of which bloom in August and September next. A. W.

MIDLAND COUNTIES.

Gooseberries and Currants.—The bushes of small fruits have been badly attacked by aphid and other insect pests, which have been very destructive amongst other fruit-trees. Only by incessant warfare can these pests be kept in check. The shoots are shortened back to five or six leaves and the trees thoroughly syringed with Quassia extract. This shortening of the shoots will favour an early maturation of the wood, especially on cordon-trained trees, and, in addition, the fruits will be greatly improved thereby. Early Cherries will be given a final cleansing of their shoots before being netted to exclude the birds, which attack the fruits directly they begin to change colour. The trees require plenty of water at this stage. Later-fruiting varieties must also be given copious supplies of water, and the foliage must be kept clear of all pests by a free use of the garden syringe. The netting of the maincrop Strawberries must no longer be delayed. Birds are apt to attack the fruits even before they change colour, and if once the attack is commenced they will be most persistent in their efforts to reach the fruits, even after the nets are placed on them. In this locality there is every prospect of a heavy Strawberry crop.

Raspberries must have their young canes tied, and should be mulched by giving the ground a good dressing of rich manure, well soaking it with water after it is applied. Remove all useless suckers, retaining those

only that are required for the production of the crop next season. Any weeds that may be growing between the stools should be kept down, as if allowed to remain they quickly exhaust the surface-soil of moisture and nutriment to the detriment of the growing crop.

Cinerarias.—Seedlings raised from spring-sown seeds should now be pricked out into boxes, which are better than small pots for the purpose. Fill the boxes with soil of a light texture containing a considerable amount of leaf-mould. Prick out the seedlings about 4 inches apart each way, and then stand the boxes in an unheated frame, under a north wall if possible, and on a bed of ashes, which should be previously well damped. Keep the frame closed for a few days, syringing both morning and evening. On warm nights the lights may be removed to allow the dew to settle on the plants, but in the morning they should again be placed on the frames, and if the sun's rays reach them shading must be afforded.

Primulas raised from seed this season should now be potted into 3-inch pots. A suitable compost consists of good fibrous loam one-half, leaf-soil one-fourth, and silver sand one-fourth. Use perfectly clean pots, or the soil will cling to the sides when turned out for repotting, and many of the roots will be damaged, thus causing a severe check. Stand the pots near to the glass in a structure having an intermediate temperature, and shade the plants from the sun's rays. As soon as they become established in the fresh soil remove them to an unheated frame.

Polyanthus seedlings are now large enough for transplanting. Choose a site on a shady border, such as under a north wall. Plant them at sufficient distance apart to enable the hoe to be plied between the rows.

Wallflowers sown early in May are now ready for pricking out. In transplanting from the seed-beds pinch off the tap-roots, as this induces the plants to make numerous fibrous roots near the surface, and, given plenty of room, nice, dwarf, bushy plants are produced. One good bushy plant is always better than three drawn, lanky ones. Plant in rows about 10 inches or 12 inches apart each way, and after they have begun to grow go over them and top them.

Pentstemons now require to be neatly supported; this is best done by placing a neat stake to each plant and looping up the growth loosely as it is made. These succeed in almost any kind of soil and are well worthy of the space they occupy and the little attention which they require.

Pyrethrums.—The varieties of Pyrethrum roseum have made a brilliant show for some weeks past. By cutting all the flowering stems away quite down to the base they may be induced to give a good second crop of most useful flowers during the autumn months. This cutting down should not be postponed a day longer than is necessary, and when the plants have again commenced to grow they may be helped by watering in dry weather and by mulching with short manure. Where cut flowers are much in request the slight labour entailed by this will be well repaid.

The rock garden.—It is necessary to go over the rock garden occasionally to prevent the stronger-growing plants encroaching too far in the vicinity of the weaker. If this is not attended to there is danger of losing some of the choicer plants. This work should be done at regular intervals, as the cutting away of too much growth at one time gives the whole an untidy appearance. Do not let the plants suffer from want of moisture.

French Beans are making good progress, and plants from the earliest sowings are in flower. The ground between the rows has been mulched with short manure, and a liberal watering applied. Small sowings will now be made weekly until the middle of July. It is much better to make frequent small sowings than to depend on plants which have become partially exhausted, the produce from young plants being much more tender.

Scarlet Runners sown early in May are now growing freely. These also have been mulched with stable litter and a good watering given. The plants should be stopped as soon as they have reached the top of the sticks in order to induce the formation of side shoots.

Celery.—All side growths and split leaves should be removed from the earlier plants, the surface soil stirred frequently, and an abundance of both liquid manure and clear water applied to the roots. Keep a sharp look-out for attacks of the Celery fly, and destroy the maggots whilst quite small by pressing them between the thumb and finger. Apply a good dusting of fresh soot once a week, early in the morning or late in the evening. The latest plants should be put into the trenches as quickly as possible; though it is more convenient to plant in single rows, it is often necessary to economise space by planting two or three lines in a single trench.

Maincrop Onions.—The dry weather of the last few weeks has delayed the thinning of this crop. Thinning is only carried out where the plants are very thick, and if the weather continues dry it will be necessary to give a thorough watering before this can be carried out. If Onions of medium size only are required the plants may be left as thickly as 2 inches apart. Onions of moderate size keep better and are just as good for cooking. The ground between the rows should be frequently lightly stirred with a Dutch hoe to keep it from cracking.

Tomatoes planted out of doors are making rapid growth. Keep all side shoots removed, and should the plants be extra strong the lower leaves may be shortened a little. No manure of any kind must be given the plants until the crop of fruit is set.

General work.—Whenever a crop of vegetables is over it is good policy to manure and dig the land as soon as possible, so as to be ready for another crop. Nothing is more harmful to the ground than allowing a plot of vegetables to stand after they have run to seed, and nothing gives a garden a more untidy appearance. Keep the hoe going as freely as possible during dry weather, so that when rain comes there will be little of that kind of work to do, and full advantage can be taken of the change to put out as many plants as possible. F. W. GALLOP.

SCOTLAND.

Planting out.—During the week bedding out has been practically finished, with the exception of the more tender subjects and the usual odds and ends which are usually left until the bulk of the planting out is completed. Provision is made in all cases for failures among the plants in beds and borders, a sufficient number of each variety being held in reserve for this purpose. Owing to the showery weather no artificial watering in the case of the newly put out plants will be necessary.

Vegetable garden.—Under similar favourable conditions the bulk of the Brassicas intended for early autumn use has been planted out. A supplementary planting of Cabbages was made, two varieties being used. These are Enfield Market and Defiance, both excellent sorts and which provide good-sized heads in September. Cauliflowers were extensively planted. A good breadth of the ever useful Walcheren was put out, and during the present season these have been planted more thickly than is usually the case. Some hundreds of Brussels Sprouts were put out at the same time. Scrymgeour's Giant and Dalkeith are preferred at this date. The next planting will consist of smaller and more compact varieties which, I think, endure a severe winter better than the taller-growing sorts. A first planting of Drumhead Savoy was made. This is not a large planting, but it gives some heads at an early period, and which are occasionally useful. Curly Kale and Hearting Kale were also got out, and these plantings will be supplemented at a later date.

Potatoes.—Second early varieties having come away very rapidly, the soil was forked up between the lines and drawn up to the stems in the course of the week. For moulding up, a small garden plough which is easily drawn by a man and a boy is used. It makes a very tidy and effective job and is very much quicker than moulding up by drawing up the soil with hoes. A considerable proportion of the late varieties was hoed through when weather conditions were favourable. Early varieties continue to make satisfactory progress, and, despite a rather inclement spring,

will not, I think, be noticeably later than usual.

Celery.—A further planting has been made, some white and pink sorts having been put out. There has been no necessity for watering these plants, and, rather dull, showery weather still continuing, they ought to go away without any check.

Parsley.—Sown out Parsley has germinated exceptionally well and has grown freely. Thinning has, therefore, become imperative, and some progress has been made in this direction. The thinnings of Parsley transplant well, but as the bed is uniform all over no need for this arises. Good pickings are now available from plants pricked off into cold frames in spring and afterwards transferred to the open.

Onions and Carrots also are ready for thinning. In the case of the Onions come use will be made of the strongest seedlings for transplanting. These make very useful bulbs, are firm and hard, and keep well, although, naturally, they are not large. Nevertheless, considering the high price, consequent upon limited importations, which was asked in late spring for Onions, it would appear to be advisable for those who have superfluous thinnings and spare ground to transplant as many seedlings as possible instead of throwing them away.

Spinach is sown from time to time as occasion requires. The dripping May has been good for Spinach, the usual wholesale bolting having been for once in a way noticeably absent. A further sowing of Spinach Beet was made during the week in order to provide against a possible scarcity in the event of the early autumn proving, as is sometimes the case, hot and dry.

Turnips are being thinned and sown as needful. White Stone is a useful variety for present sowing and one which matures quickly.

Peas during the week were staked, and further lines were sown. Growth among the previously-sown varieties is well maintained. Present sowings included a line of Ne Plus Ultra, a reliable old sort if a true stock can be obtained.

French Beans.—Some lines of these were thinned to a foot apart. One is, at times, apt to overrow Beans of all kinds, but thinning is well repaid. A further line of Climbing French Beans was sown, and with the sowing of a couple of long lines of Canadian Wonder in a fortnight's time the sowing of French Beans will be completed.

Sweet Peas.—Stakes were placed to Sweet Peas which were sown out. Small Spruce branches had been previously put in to protect and to support the seedlings, and now the permanent tall stakes were supplied. Sweet Peas raised in frames and planted out were given a look round, and where necessary were lightly secured to their wire supports. The earliest tier of buds is visible, but as the sun is absent and the nights cold it is more than likely that these buds will drop. This is, however, to the ultimate benefit of the plants, even although the earliest Sweet Peas are always welcomed.

Peaches and Nectarines on walls.—From time to time thinning is being done as opportunity offers. There is a full set, and much thinning will be needed, which, however, will be spread over a considerable period. As was anticipated, the variable weather and the cold nights have induced an outbreak of leaf-blisters upon Nectarines. This cannot be dealt with until a period of settled weather comes, and in the meantime the worst of the infected leaves are being removed. With more genial weather blistering ceases, and, so far as my observation goes, it is more unsightly than dangerous, although, of course, it were better absent.

Strawberries.—Prospects of a good crop appear to be satisfactory. Bloom is plentiful, frosts have been absent, and there has, above all, been sufficient moisture. There seems to be a disposition now to avoid Royal Sovereign because spring frosts so often cut the bloom of this variety, which comes early. Nevertheless, those who grow this Strawberry in a place where the morning sun does not reach it early after a night's frost will find it useful. When well done, Sir C. Napier yet remains a good late variety.

Ventilation and Vines.—Those who are careless in the matter of ventilation assuredly have not their troubles to look for. Beyond question, careless or unequal airing is to a great extent responsible for scalding, cracking, spider, and mildew. A little air may safely be left on all night now. The merest chink at the apex of the house will keep the air moving in the house and prevent the condensation of moisture on the berries. The amount of ventilation ought to be increased as the thermometer rises; but at no time should a sudden volume of cold air be admitted. Increase the ventilation as the temperature rises, and gradually reduce it during the afternoon.

Hardy-flower borders.—The taller and more robust plants now making vigorous growth require periodical attention in the way of tying up. It will be noticed that if these are not regularly attended to in this respect they are quite as likely to be beaten down by heavy rains as by high winds. During the present season the experiment of leaving some of the dwarfier varieties unstaked is being tried. Phloxes, Pæonies, Enothers, the dwarf Asters, and so forth, are being thus treated. In the case of Pæonies now in bloom, the rains have not done any damage, and the plants certainly look much more natural than they do when supported by Spruce twigs or when loosely tied in to stakes. The display of bloom increases almost daily, but a spell of dry weather would be welcomed in order that the crop of seedling weeds due to the wet might be got rid of. W. McGuffog.

Balmae Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Pæonies diseased (B. H.).—Had you sent us some pieces of the diseased plants, we then could have been better able to help you. Judging from what you say, your plants are affected with a fungoid disease known as Botrytis Pæoniæ, and your only remedy is to collect and burn all the affected parts. As it is more than likely that the germs of the disease remain both in the tissues of the plant and the surrounding soil, you had better burn all the foliage and some of the surface-soil around. Then in September lift the plants, and after washing away all the soil, give them a sulphur bath before replanting in fresh soil.

Winter-flowering Pelargoniums (W. F.).—Any varieties of the Zonal type of Pelargonium will bloom well in the winter if prepared for that purpose. To that end get nice spring-struck cuttings, now in small pots, shift into 5-inch pots, and keep them growing on in a frame or greenhouse (cool), and from time to time pinched so as to make them bushy. They must not be allowed to flower. Then, a few weeks hence, shift them once more into 6-inch pots, and, after keeping in a frame for a week or so, stand them outdoors on a hard ash floor in the sun to harden the wood. Keep freely watered, and occasionally turn them round. Continue to pinch up to end of August. At the end of September get the plants into the greenhouse, and give a moderate temperature of from 50 degs. to 60 degs., and they will then bloom profusely for some months.

FRUIT.

Ivy and fruit-trees (M. O.).—Your fruit-trees are suffering, without doubt, from such close contiguity to the Ivy on the wall behind them. No doubt, such Ivy, which is old and covers the wall, has a perfect network of roots that eat up the soil and greatly impoverish it. We should expect that, being only 18 inches from the wall, the roots of your fruit-trees are starved and strangled. If you cannot or may not destroy the Ivy, then you must resolve next autumn to remove your fruit-trees elsewhere. No doubt, the Ivy roots extend and feed greedily on the soil fully 7 feet or 8 feet from the wall, probably even much further away.

Silver-leaf on Plum-tree (F. P. Grandin).—Yes; the shoot of Plum-tree you send us has been attacked by the silver-leaf fungus, for which, so far as we know, no remedy has yet been found. If the disease makes any head-

way, then your best plan will be to grub up the tree and burn it. If you purpose planting a young Plum in its place, then you must be careful to remove all the old soil, as there is just the possibility that some of the spores will be present in the soil and attack the newly-planted tree. If you decide to plant any other tree bearing a stone fruit, then there will be no need to remove the soil, but care should be taken to remove all the roots of the Plum-tree, otherwise such would breed fungus.

VEGETABLES.

Cucumbers cankering (R.).—Your Cucumber plants are suffering from a complaint that every grower knows. Sometimes it is attributed to over-watering, sometimes to soil being too light and porous, sometimes to sourness. Wherever it gives trouble water should never be given near the stems, and a little lime may be heaped up round them with advantage. The trouble always shows itself just on the surface of the soil, and seems always to be associated with water contact. Sometimes it has occurred through the twisting or bending of the stems, such as happens when plants are grown on the soil and are not tied up erect.

SHORT REPLIES.

Sedum.—"Cactus Culture for Amateurs," by W. Watson. This, no doubt, could be had through any bookseller. We do not recall any firm which now issues a catalogue for succulents or Cacti.—**Quicklime.**—You may use the lime-water when clear for destroying slugs and worms in pots or in lawns, but you must not water plants overhead with it, as it leaves a sediment on the leaves.—**Puzzled.**—We do not think that woodlice are the culprits. You will find that the loss of your seedlings is due to slugs, which are very numerous this season owing to the rains we are having. Dust the plants with fresh lime to destroy the slugs.—**Rockdene.**—We should not trouble to keep the plants. You will find it far better to raise a stock from seed every year, as such will be far more vigorous, and, in consequence, flower better.—**Miss Wootton.**—Impossible to say what disease has attacked your Gentian. Please send a complete plant, including the roots.

NAMES OF PLANTS AND FRUITS.

Names of plants.—H. H. Hartley.—The Caper Spurge (Euphorbia Lathyris).—M. Gloyne.—Ceratium tomentosum.—Anon.—1, Saxifraga umbrosa var., we should like to see a complete rosette; 2, Send in flower, please; 3, Veronica rupestris; 4, Helianthemum vulgare, var. mutabile.—W. Howard Bell.—Genista tinctoria, var. mantica.—(A) B. G. L.—Nepeta Mussini.—Robt. Greening.—Saxifraga Camposi.—X. Y. Z.—1, Sedum oppositifolium; 2 and 3, Varieties of Saxifraga cuneifolia; 3, Most nearly resembles that known in gardens as taygetea; 2, Was not in flower; 4, Saxifraga umbrosa serratifolia.—J. E. Kelsall.—Hibiscus syriacus Bleu Celeste.—E. B. Tucker.—Anemone obtusilata (Don).—W. D. Hallifax.—1, Saxifraga aizoon minor; 2, Primula, please send more complete specimen, including leaves.

The dumping of bulbs and plants.—At a recent meeting of the Horticultural Trades Association of Great Britain and Ireland, attended by upwards of 100 delegates from all parts of the United Kingdom, representing the nursery and seed trades, it was resolved to petition the Government to take steps to prevent the dumping of foreign-grown trees, bulbs, shrubs, plants, etc., on our markets after the war, more especially from those countries with which we are now at war, due regard being paid to the interests of our Allies. In a letter addressed to the Prime Minister and leading members of Parliament it was pointed out that large accumulations of stock are taking place in Continental nurseries where no export trade whatever has been done for two years, and that if this is allowed to be dumped on our markets at the conclusion of the war, a trade which had perhaps suffered more heavily than any other through the war would be absolutely ruined.

200 BEDDING PLANTS, 2/-

5 LOVE LIES BLEEDING GRATIS.

6 Crampel Geraniums, 6 Calceolarias, 6 Cactus Dahlias, 12 Asters, 12 Stocks, 12 Tropæolums, 10 red Marguerites, 10 Schizanthus, 12 Asters, 12 Stocks, 10 Gaillardias, 12 Window Plants, 6 scarlet Salvias, 20 Alyssum, 20 Mignonette, 20 Marigolds, 10 Climbing Hops (variegated), 6 Foliage Plants, all packed separate and free on rail for 2s.

12 EARLY CHRYSANTHEMUMS, 1/3.

Double and single early flowering varieties, some of the newest and latest varieties, 12 for 1s. 3d.

12 TOMATO PLANTS, 1/2, Carriage paid.

Carters' Sunrise, Ailsa Craig, Best of All, Kendine (red), Full Basket, etc., etc. A customer writes: "I had 10 lbs. of fruit from your Sunrise last year."

12 LARGE CALCEOLARIA PLANTS, 1/3.

Orange, yellow, or bronze, fine plants, free on rail, 1s. 3d. doz.

GERANIUM NEW SALMON PAUL CRAMEL.

1 doz. strong plants, 2s., a most glorious colour.

THE ROSELESS GARDEN.

Most people in trades are liable to become stereotyped in their ways, and few more so than the British nurseryman. Able and successful as he is, he takes a short view in some ways, and the Rose is by him only grown in one way—that is, grafted on the Brier. If one speaks to one of these able men in England and the north of Ireland of another way of propagating Roses, he may not say so, but he will probably look upon you as mentally deficient. The prejudice of these men is extraordinary. Roses do very well in heavy lands, and in one way and another, from catalogues and books, people get the idea that the Rose will not do well on certain dry lands, as in Surrey. I have made an attempt to get a friend there, who lives on hot sand, to give up the ordinary way of getting Roses from the trade and try them on their own roots, but I failed. I see a writer in *The Garden* bears out what I say:—

We have been here sixteen years, and at first wasted much money on buying Roses, sometimes English, sometimes French grown. They were all on Brier stocks and did well the second year, not so well the third year, and after that were only fit to throw away. I then noticed that all the plants of Zephirin Drouhin flourished, and as they were all on their own roots I decided to try growing all Roses on their own roots and to abandon such as would not grow in that way. The trial of the last eight years has convinced me that for this garden it is the only way to grow Roses. We strike the cuttings under bell-glasses. A good mud pudding is made and the cuttings pushed into it. The bell-glass is turned down over the cuttings and also pushed into the mud, and is there left until the following spring. I doubt if it is necessary to prune Roses which are on their own roots as hard as those which are on stocks. May I add (although I have already given the information in *The Garden*) that we are now never troubled with mildew, because we always sprinkle the ground with quicklime before the trees come into leaf. It seems possible that mildew spawn lies on the surface of the ground during the winter. On the other hand, this soil is very short of lime, and this extra lime added in this way may be sufficient to make the Roses

grow strong and resist the mildew. There can be no doubt that green-fly cannot live on any plant which is healthy and growing strong. If anyone doubts it, let him try watering with liquid manure a Rose-tree which has greenfly on it, and he will see the fly die in a day or two. I have never known the experiment to fail on this soil, although sometimes more than one dose is needed.—THACKERAY TURNER, *Westbrook, Godalming.*

There is hardly anyone who comes to see my garden who does not say that my success with Roses is all owing to the soil. Some go on putting Roses into the dry, sandy stuff, where they soon perish. Nurserymen who persevere in their ways with Roses and give people no choice, do themselves harm by limiting the uses of the Rose to heavy soils. The Brier is a native of heavy land. Even on such land it often fails, and some Roses will not put up with it, while others, like Rêve d'Or, will live for years. In its case there is some natural relationship, but in the best Rose soils many kinds of Teas and Chinas gradually die back, and people wrongly impute the failure to the climate.

In the face of the present state of things in Rose nurseries, the only way for those with dry soils is to strike the Roses from cuttings. The common idea that it is a slower way is a delusion. If stout cuttings are put in in September, even in the open air, one may often get a strong plant in the course of a year. The poorest sandy soils are amenable to improvement; one may deepen them, but one should never put a Rose on the Brier in them. China Roses are twice as good on their natural roots, which are of quite a different nature from those of the Brier.

W.

NOTES OF THE WEEK.

The Phenomenal Berry, ripe and fit for table, comes from Mr. W. Allan, at Gunton. It has not so much core or pith as the Logan, and, when cooked, is delicious.

Campanula rhomboidea alba is a variety we received from Petrograd. It usually grows about 1 foot high, but is taller this year. It is a fine, long-flowering plant and of robust constitution. Its light green, healthy foliage also adds to its appearance.—J. STORMONTH & SONS, *Kirkbride, Carlisle.*

Apple and Pear crops.—Apples and Pears seem a dead failure this year round about here. I hope, as you have no reference to the subject in your pages, that the failure here is purely local.—J. D. THORBURN, *Upton Cross, Chester.*

Trillium sessile californicum and T. s. c. rubrum.—These two are now nearly over, as they bloom before T. grandiflorum (about a fortnight or three weeks) and yet outlast that variety.

[Very picturesque Trilliums and well worth growing. From Mr. Stormonth, Kirkdale.]

Genista tinctoria mantica.—The Dyer's Greenweed, too common in many fields, has some interesting variations, and among them the above, a handsome plant with downy leaves and stems, and well worth growing. According to W. J. Bean this variety flowers earlier than the ordinary G. tinctoria. From Cleeve House, Wilts.

Roscaea cautioides.—This graceful species is now (beginning of June) in blossom. The flowers remind one strongly of those of an Orchid, and are of a lovely pale yellow colour, carried in bunches of five or six at the end of stiff stalks. It is a native of China, but seems to be pretty hardy if planted with the fleshy roots 4 inches or 5 inches deep in light soil in a sunny, sheltered position.—NORTH LONDON.

Tolmia Menziesii is a strange Heuchera-like plant for any moist spot. Its brown flower-spikes are freely borne and the plant is not liable to die away as does the Heuchera. A curious feature is the young crowns, which are formed at the base of the leaves. Old stems get weighed down as these youngsters develop, until they reach the ground, when they take root.—J. STORMONTH.

Rhododendrons at Terregles, Dumfries.—On a bank by the side of the stream which has been formed into a series of lakes at Terregles, the seat of Mr. C. E. Galbraith, there is a fine collection of hybrid Rhododendrons, which have been very good this season. They were strikingly beautiful viewed from the opposite bank, the reflection of the bright colours in the water below adding to the beauty of the scene.—S. A.

Brugmansia suaveolens.—Few things are more beautiful than this when in bloom. In early May I was charmed with this and Begonia corallina growing side by side in a greenhouse at Hawley Hill.

The two were planted at the foot of the back wall, and when they reached the top of the trellis they were trained down the trellis several feet. In this way the blooms of both hung down, the white flowers of the *Brugmansia* and the bright pink blooms of the *Begonia* making a lovely picture.—WEST SURREY.

The Laburnum in south-west Scotland.—The Laburnum is highly appreciated in the south-west of Scotland, and, especially in the suburbs of the towns, it occupies an important position. It is interesting to note the variety of habit in individual specimens, and a little care in the selection of seedlings would tend to eliminate the less graceful forms. Some of the forms of the alpine Laburnum are very graceful, the pendulous habit rendering still more effective the long racemes of flowers produced by the best varieties.—S. A.

Saponaria ocymoides.—What a lovely trailer this is for a sunny wall. It is just now at its best, and a patch of it over a yard square is so crowded with its bright, rose-pink blossoms as almost to hide the foliage. It is easily raised from seed, but must have plenty of room, as it spreads very fast. As soon as the flowers go off the seed-heads should be cut off, otherwise the plant becomes exhausted and dies. It does splendidly planted in the chinks of a retaining wall, but I do not find it very long-lived. It also grows quite well on the flat if in light, stony soil.—N. L.

Rhododendron Pink Pearl.—Mr. Gomer Waterer must not suppose that I intended to throw any doubt upon the claim of his firm to have raised the original Pink Pearl. I merely repeated a definite statement made to me in Edinburgh upon what I considered good authority, attributing the raising of this fine hybrid to the late Mr. Peter Lawson. If I remember rightly, Mr. Waterer, in his note to the *Field* newspaper, declined, or at all events omitted, to disclose the parentage of Pink Pearl. This he has now done, for which many persons interested in the cultivation of Rhododendrons will be grateful to him. I know nothing about the origin of Alice.—HERBERT MAXWELL, *Monreith*.

The Oriental Poppy (*Papaver orientale*) naturalised.—It has been interesting to observe a large drift of this during the past few years. Naturalised in a sunny meadow, and intermingled with Moon Daisies, Buttercups, Grasses, and various other wild flowers, the plants in early June produce an effect such as would be impossible in the cultivated garden. The flowers, rather too short-lived for the garden borders, often early in the year present a dismal appearance when so employed. Naturalised, they require no attention whatever once they are planted. A beautiful form of the Oriental Poppy, stronger and more erect than the type, is *P. bracteatum*, which produces gorgeous blood-red flowers each 9 inches across, with dark blotches at the base of the petals. This is a splendid flower for indoor decoration, lasting well if cut in early morning just before the buds open.—E. MARKHAM.

The Chilean Fire Lily (*Habranthus pratensis*).—This, referred to on page 294, is not seen in gardens so frequently as it deserves. It is quite hardy if planted 4 inches or 5 inches deep in warm soil in a sunny, sheltered position, though in severe weather it might be safer to mulch with dry leaves or ashes. I have it in a sheltered, sunny pocket of my rock garden, and it is just now a beautiful sight. The flower-stems are each about 1 foot or 18 inches high, and carry from four to seven flowers on each of a brilliant

orange-scarlet colour. I find it is advisable to lift the bulbs every two or three years as soon as the foliage has ripened off, which is about the beginning of July, and divide them, replanting them in soil with a good admixture of sandy leaf-soil incorporated with it.—NORTH LONDON.

Raising Cineraria seedlings in the open air.—I have a gardener friend who raises his principal stock of Cinerarias from seeds in the open air. When his plants have finished flowering he places the pots on a Rose-bed, where the seeds ripen. He allows his seedlings to remain in the beds till they have formed three or four rough leaves, when he lifts them with a little soil adhering to the roots. After lifting, they are grown on in the usual way. He finds this an easy as well as a good method. He has a nice lot of seedlings up now (June 9th).—D. HANNIGAN, *Rockford Gardens, Nenagh, Co. Tipperary*.

The Mountain Avena (*Dryas octopetala*).—This charming little plant has been in bloom for some two or three weeks, its large, white, Anemone-like flowers, rising 2 inches or 3 inches above the mat of crinkled "Oak-leaf" foliage, being always admired. Mr. Farrer speaks of the foliage as evergreen, but with me it is not so, dying off, or nearly so, in the winter. It likes a sunny spot, not too dry, and seems to prefer a little lime in the soil. It is propagated by layers or seeds, the former method being, perhaps, the easier. Though it flowers mostly in the spring, a few blossoms are thrown up now and then all through the summer.—N. L.

Meliosma cuneifolia.—The introduction of several species of *Meliosma* to this country during the present century has made it possible to include amongst our outdoor shrubs representatives of a genus which before had been scarcely known outside botanic gardens. *M. cuneifolia* is a vigorous bush from Western China, where it is said to grow from 12 feet to 20 feet high. Its large, deciduous leaves are up to 7 inches long and 3 inches wide, and distinct by reason of their prominent veins. The chief charm of the plant is found in its large, erect panicles of small, fragrant, cream-coloured flowers, which, as they advance in age, become almost white. On a vigorous specimen these inflorescences may be nearly 1 foot in length, and as they are borne freely have a very imposing effect. It was introduced in 1901, when Mr. E. H. Wilson sent seeds from China to Messrs. Veitch. Plant in rich loamy soil in a position exposed to sun, but sheltered from rough and cold winds. Another interesting species introduced from China by Mr. Wilson about the same time is *M. Veitchiorum*, which can be easily distinguished by its pinnate leaves. It bears even finer inflorescences than *M. cuneifolia*.—D.

Lathyrus rotundifolius.—For beauty this Pea can scarcely be surpassed by any other of its family, embracing, as it does, all the essential qualities of a first-rate, hardy perennial, being vigorous in growth, free-flowering, lasting in bloom for a considerable time, and giving little or no trouble once it has become established. It is one of those fine old plants which are all too frequently missing from good gardens. With me it is growing at the foot of an oak-pale fence in heavy, sticky soil. In this position it is, when in bloom, a magnificent sight, and is admired by all who see it. The healthy, robust growths, each 6 feet in length, throw out branching shoots 2 feet in length from the leaf-axils; also a spray of flowers. These flowers are produced on stems a foot in length. The colour is a lovely orange-red. For cutting,

the flowers are invaluable, as they may be gathered in sprays 3 feet in length, and when used for draping mantel-shelves, window-ledges, or tall furniture their decorative qualities are seen to great advantage. The other day I measured a plant and was surprised to find it was 6 feet high by 9 feet through. Its robust, healthy constitution, earliness to bloom, and graceful habit should recommend it to all who value good, hardy plants. It is easily raised from seed, which ripens freely in favourable seasons.—E. MARKHAM.

Robinia Kelseyi.—This was introduced to English gardens about 1903, a couple of years or so after it was recorded in America. Its origin is somewhat of a mystery, for although first noticed in a nursery in Boston, U.S.A., the proprietor, Mr. Harlan P. Kelsey, could not satisfy himself as to whether it was a natural hybrid or a new species the seed of which had been introduced with something else. Whatever its origin, however, it is an excellent shrub or small tree. Of loose habit with light, elegant leafage, it grows 8 feet or 10 feet high, and during the latter half of May and early June bears freely rather dense clusters of attractive rose-coloured flowers, the blooms being rather smaller than those of the Rose Acacia, but similar in colour. It grows well in loamy soil, but to get it to assume tree-like habit it is necessary to keep the leading shoot clear by cutting back the side branches. Only those plants that are naturally erect and vigorous should be chosen as trees, the others being allowed to develop as bushes. Like the Rose Acacia, its branches are brittle, therefore it should be planted in a sheltered position. Seed-pods covered with stiff, bristly, reddish hairs are produced freely, the shrub differing in this respect from the Rose Acacia, which does not perfect seed-pods.—D.

The English Bluebell.—It is undesirable to pass over without mild protest Mr. G. H. Raynor's note on the Bluebell, because it encourages the promiscuous coining of names for colour-varieties of plants, which is deplored by every experienced botanist. There are far too many names and synonyms already. The Bluebell is a case in point, for after various changes it is now called *Endymion nutans* (Dumort) or *E. non-scriptum*. It is certainly not a *Scilla* any longer. Your correspondent says that "works on English botany seem lamentably deficient in this respect" [the naming of obscure colour-forms which may or may not be constant], "but one gets more help from nurserymen's catalogues." Nurserymen are the chief sinners in this respect, and for obvious reasons, but some are laudably doing their best to prevent further chaos. It is well known that blue flowers are particularly variable in colour in Nature; blue Gentians, Veronicas, *Phyteumas*, Campanulas, and Boraginaceous plants frequently vary in colour from white, through pink and mauve, to deep purple. It is sometimes a question of soil, aspect, or other physical circumstance. But the authors of works on the British flora are not alone in wisely refusing to give varietal names to all these colour-forms. That they may be cultivated, as Mr. Raynor is doing, and carefully watched from year to year is, however, to be encouraged. It may interest some of your readers to know that the Bluebell's place in Switzerland and the whole of eastern France is taken by the bright blue *Scilla bifolia*; but the Bluebell reappears in Piedmont and Lombardy, and gets as far west as Spain and Portugal.—H. S. THOMPSON.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

TYERMANN'S KINGCUP.

ONE of the forms of our great native Kingcup, dwarfed, very compact, and free blooming. It is grown in a tank in a pot and has not therefore a full chance for its roots as it would have in rich soil or mud near water.

HARDY FLOWER NOTES.

GENTIANA IN THE GRASS.—Has Mr. Markham, who writes in a recent issue on spring flowers in the Grass, tried *Gentiana verna* and *G. acaulis*. For years the late Mr. Wilson tried *G. verna* in various positions in a garden that afforded much variety in the matter of soil and position, but he could not induce permanent vigour. The plants did very well for a year or two and gradually declined in health,

home. The soil is of that light, porous character which abounds in Surrey.

SEDUM ANGLICUM.—Beginners in the culture of alpine plants should beware of this. It is just the kind of plant that is calculated to please the inexperienced, being of neat habit and very free-flowering. Whether it seeds very freely or whether tiny pieces become detached I cannot say, but after a time the grower, to his dismay, will find that it proposes to take up its residence in the hearts of his most precious possessions, and, if left alone, chokes them out of existence. The only safe way is to keep it out of the garden altogether. In any case take care that it does not steal a march and make an unexpected appearance in the alpine garden. I have been tormented with this plant for years. To all appearance I have more than once destroyed every vestige of it, but the following season it has sprung up again. When it gets possession of things of a close, tufted habit like *Saxi-*

of *A. Robinsoni* is very welcome. Although the name is misleading, for only by a stretch of imagination can the flowers be termed blue, it is certainly distinct, and there is a refinement in them which is very attractive. I am wondering how this *Anemone* originated. Was it discovered growing wild, or is it a garden variety? I am inclined to think the latter, and it is probably a seedling from *A. Robinsoni*, although I have every now and then information of coloured flowers of the type growing in woods, but too far away, unfortunately, to enable me to visit the localities. J. CORNHILL.

FLOWER GARDENING IN HYDE PARK.

WE notice that the sheep which usually browse in the grassy spaces of the park now lie about and take their ease on the beds which, in other years, were used for displays of annual plants, but now, for reasons of economy, are mere mounds of bare earth. Inasmuch as good comes out of evil sometimes it may be opportune to say that the whole of the vast display of bedding plants along the Park-lane side was never right, and never artistic. There were too many beds; there was not verdure enough between them, nor the relief which shrubs and trees would have supplied. Less than half the number of beds would have been more effective. The devotion of that immense tract to bedding plants alone was a costly and foolish extravagance. Much of the cost that went to this extravagant display, if given to the growth of hardy flowers in the Grass in the vast areas of the London parks would have given us a spring garden safe from any calamity of war or other misfortune. The ground is excellent for the naturalisation of beautiful things like the *Globe-flower*, the *Narcissus*, the *Crocus*, and all the early flowers.

The whole of the Park Lane garden side of the Park should be altogether rearranged by some person of taste and full knowledge of hardy shrubs. Much more should be made of hardy shrubs and trees, instead of eternal efforts for the tender and short-lived things that cannot show their beauty until the summer is well with us.

BEAUTY IN HEDGEROW AND MEADOW.

I READ with much interest and pleasure the note on the above by "E. B. S." (page 297). There is much natural beauty in all our counties, but more of it and in more variety in some than in others. I once saw a grand display of Foxgloves, Thistles, and Ferns on a bank near a wood, with immediately behind the bank Honeysuckle clothing a Fir tree to a height of more than 50 feet on one side, and on the other Honeysuckle furnishing an Oak about 20 feet high. The Honeysuckle depended gracefully from the branches of the Oak and formed a charming object. "E. B. S." says he misses three things in his neighbourhood—namely, Gorse, Heather, and the common Fern. In this district, bordering on and in the New Forest, there are hundreds of acres of each kind in addition to wild flowers in great abundance. I have seen many acres of Bracken growing to a height of 9 feet. There are many acres of low-growing Gorse dotted with huge clumps nearly 20 feet high in sheltered parts; then the Heather follows, forming edgings to the public roads in many parts. There are scores of large dwelling-houses in the neighbourhood placed, as it were, in a setting of Gorse, Heather, and Ferns. The

Part of a group of Tyermann's Kingcup (*Calltha palustris Tyermanni*).

which is what generally happens to this lovely little hardy plant. Then by a happy thought several plants were put into the Grass, and they at once took on that happy appearance which hardy plants only have when everything is to their liking. Readers must not, however, take it for granted that this *Gentian* will thrive in all places under such conditions. In low-lying situations where the Grass is very lush it would be smothered. In what are commonly called upland meadows, where the herbage is finer and where a certain amount of light penetrates and air freely circulates it would probably succeed. The nature of the herbage is determined by the character of the soil and by altitude. The lower down the coarser the Grass, and in this only strong-constituted things can flourish.

EPIGÆA REPENS.—Since writing the notes on this, which appeared in *GARDENING ILLUSTRATED* weeks ago, an amateur informs me that he has it established under Fir-trees. He says that "it is running," a sure sign that it is quite at

fraga oppositifolia the case is hopeless, and nothing but transplanting will avail, and even then tiny bits are apt to remain.

ANEMONE NEMOROSA BLUE BONNET.—Not very plentiful at present, and absent from the majority of trade lists, this *Anemone* is sure to become popular. It has a close family resemblance to *A. Robinsoni*, but differs materially from it. It is curious that it starts into growth much later. It is one of the last of the early spring flowers to make its appearance above ground, and for that reason will, I think, never become so plentiful as *A. Robinsoni*. Although coming into flower so much later, the foliage dies off at about the same time, therefore the season of growth is shortened, and for this reason the rate of increase is necessarily slow. Even when in full growth it is not nearly so vigorous, and seems to require a very free soil, and is not likely to do more than live on from year to year in soil of a rather close, moisture-holding nature. It is, however, a dainty little thing, and coming as it does on the heels

district lacks lime but abounds in iron, and I daresay the iron accounts to a great extent for the richness of the colours of the flowers.

In the New Forest itself, where hundreds of horses and cattle graze, there are extremely handsome specimens of the white and pink-flowered Thorns, and as the cattle eat all the young shoots as high as they can reach, the trees resemble huge bouquets. Honeysuckle is plentiful everywhere; Foxgloves group themselves on banks; the Poppies, too, favour railway banks and cornfields, and the English Orchis stars many commons, fields, and meadows around. BOURNE VALE.

NOTES AND REPLIES.

Planting out Carnations.—I have a large batch of good Carnations of the perpetual or winter-flowering class which will soon be over. If these were cut down, planted in frames, and wintered there, would they be suitable for the borders next summer?—ESSEX.

[The old plants to which you refer would be of little value for the border next year, and would hardly repay you for the attention necessary for the ensuing twelve months or thereabouts. Healthy cuttings from the same plants inserted in July, or in the earliest days of August, and grown steadily on in cold frames, with a couple of stoppings or pinchings before March, 1917, would do you much greater service. Such cuttings would root in a month and could be potted into 3-inch pots without delay. A month later a small shift could be given, to be followed in January next by a final shift into 5-inch pots, from which size, in April, they could be put out into the border. Carnations of the perpetual-flowering class resent transplanting generally, and old plants particularly so. Your only hope with the old plants would be to cut them back after flowering and retain them in their pots, plunging them in a frame, and giving but little water till the planting-out season arrived.]

Herminum pyrenaicum.—As "E. M." says at page 294, this is remarkably easy to grow, and I have never found it give any trouble in sun or shade, in a dry soil, or in one with a considerable amount of moisture. As "E. M." says, it is "not one of the choicest alpine plants," but it is certainly one of the dependable ones. Its principal defect appears to me to be the dullness of the colouring; another is that when the plant becomes large it does not flower very freely. By the way, one seldom finds any mention of the white variety, which never seems to have caught on.—S. ARNOTT.

Aquilegias.—These old-fashioned flowers are very beautiful, and some of the species rank among the choicest of hardy flowers. Even the common forms are pretty, and may be planted freely in the Grass. The rare mountain kinds, of which *A. glandulosa* is a type, are more difficult to grow, but, apart from these kinds, a class of hybrids with long spurs is procurable, these being equal to the best named species, and having the advantage of a constitution as strong as that of the common Columbines. Seeds of these may be sown now in the open ground. The plants need no protection during winter, and will be useful next spring. Some prefer to sow under glass early in the spring, and prick out into pans or boxes, harden off in cold frames, and transplant into the borders in July or August. Seedlings raised by sowing now in the open produce quite as good results, but they take a season longer to attain to flowering size.

Verbascum olympicum.—Although, perhaps, this Mullein is more suited for grouping in shrubberies, yet isolated specimens in a mixed border are effective. Reaching a height of 6 feet and over, branching freely, and covered with multitudes of primrose-yellow blooms, the spikes attract attention just at present

(June 6th) and contrast well with the spikes of *Lupinus polyphyllus*. Its white, woolly massive foliage renders the plant additionally noticeable, and although only of biennial duration, no difficulty is experienced in maintaining a supply of young plants, self-sown seedlings coming up freely.—W. McG., *Balmae*.

The variegated Cocksfoot (*Dactylis glomerata variegata*).—Many do not care for variegated plants, but this variety of Cocksfoot is very useful in beds of summer flowers. It is alike valuable as an edging plant or for mixing with such things as Tufted Pansies. A long narrow border planted with alternate pieces of this *Dactylis* and a pale-blue Pansy, such as, for example, Maggie Mott, may be depended upon to produce a good effect. *D. g. variegata* also looks well when associated with Iceland Poppies; and similar combinations will readily occur to those who use the Cocksfoot. While it will flourish in almost any soil, yet it is liable to assume a rusty appearance in a poor staple.—W. McG.

Violets.—The recent rains have been of much assistance in establishing newly-planted Violet runners. A thin mulch of old Mushroom-bed manure has been given to assist in retaining moisture and encouraging a free growth. When the foliage assumes a yellow tint it is almost a sure indication of the presence of red-spider, and a thorough syringing such as will reach the underpart of the foliage should be given, using a solution of Gishurst compound, repeating the operation at intervals of a day or two until the pest is eradicated. An occasional dusting of well seasoned soot will be of benefit, and the soil between the rows should be hoed frequently.

The Water Avens (*Geum rivale*) **Leonard's variety.**—"N. L." (page 297) is quite right in advocating the claims of Leonard's variety of the Water Avens. It is much brighter than the ordinary one, and, especially by the water side, is quite pretty with its drooping coppery-red flowers. This variety looks especially pleasing when planted at the top of a low retaining wall and just above the level of the eye. When the plant comes between the observer and the sun the colour and habit of the flowers give special pleasure. I believe the variety was found by the late Mr. H. Selfe-Leonard, of Guildford, in Norway.—S. ARNOTT.

Morina longifolia.—Morinas are distinct border plants in their season, and help to give character to the garden. Of the few species in cultivation *M. longifolia* is the best known and most easily procurable. It forms a rosette of long, ornamental, prickly, Thistle-like leaves, from amid which rise long, handsome spikes each 2 feet or 18 inches high, bearing long-tubed white and rose flowers. *M. longifolia* is not always long-lived, and in some places it is necessary to treat it as a biennial. In good, not too heavy, soil it is sometimes a true perennial.—S. ARNOTT.

The Snowdrop Windflower (*Anemone sylvestris*).—This has been very good with me this year, both the single and double forms having bloomed very freely. It seems to like an open, sunny position, and to be quite indifferent as to soil, provided it is well drained. It spreads quickly, and a good stock can soon be obtained by dividing the clumps. The single form is very like a miniature *Anemone japonica*. It flowers in May and sometimes throws up a few blooms in the autumn too.—N. L.

Perennial Candytufts.—These are valuable for the enduring nature of the bloom. A patch in my garden this year has been in flower for five weeks, and now, in the second week in June, is almost as full of bloom as it has ever been. There are many kinds, but I doubt if any can surpass *coreaefolia*. The new Snowflake is good. Where shelter can be given, or grown in a cold house or frame, *I. gibraltarica* is lovely.—J. CROOK.

Cheiranthus Marshalli from seed.—This is the most distinct and beautiful Wallflower we have. During May it was lovely in my garden mingled with Forget-me-not. This Wallflower was raised from seed, and when the plants were strong enough they were planted among the self-sown *Myosotis*. In my young days this Wallflower was increased from cuttings, but seedlings are far more vigorous.—DORSET.

INDOOR PLANTS.

HIPPEASTRUMS.

THE different garden varieties of *Hippeastrum* made a goodly show at the recent Chelsea exhibition. The display set up by different exhibitors served to emphasise their value for decoration at this season, as their large, gorgeous blossoms stand out from those of any of their associates. One thing that militates against the more general cultivation of *Hippeastrums* is the widespread idea that a considerable amount of heat is necessary for their successful culture; indeed, they are often looked upon as requiring a stove temperature at some period of their growth. This is far from the case, as they can be grown in a greenhouse where a winter temperature of 45 degs. to 55 degs. is maintained. When the flowers are over the plants should be encouraged to make good growth by keeping them well supplied with water, and giving them an occasional stimulant. Liquid manure and soot-water combined are very good for the purpose, but, failing this, one of the many concentrated plant foods now on the market may be used. Care must, however, be taken that it is not given them too strong. During the summer *Hippeastrums* may be readily grown in frames out of doors, shading them a little at first, and inuring them to the full rays of the sun towards the end of the season. As the leaves turn yellow the water supply must be lessened, and finally in the depth of winter it may be discontinued altogether. Care must be taken to remove the plants to the greenhouse before frost sets in. Being dormant, they are by some stood underneath the stage, but such treatment cannot be recommended, as the drip from the plants above may soon do a deal of harm. By February the plants can be lightly watered, taking care that it does not enter the crown of the bulb, but is just sufficient to moisten the soil. At one time the bulbs were annually repotted in January or February, but such treatment is now not considered necessary. Provided the roots are in good condition the necessary stimulus may be given in the shape of liquid manure.

REPOTTING.—There are differences of opinion as to the time to repot, for while many do this when the bulbs are dormant, others prefer to carry out the work directly the flowers are over. This cannot be then done if the plants are carrying seed-pods, while if the roots are not in good condition repotting early in the year is the better way. If the flowers have been fertilised it will be found that the seed-pods quickly develop, so that, as a rule, by July they will turn yellow and split, thus exposing the black-winged seeds.

RAISING FROM SEED.—Where there is a structure in which a temperature of 50 degs. to 60 degs. is maintained during the winter the seed may be sown at once. At this season the young plants quickly make their appearance, and if potted off when sufficiently advanced they will become established in small pots before winter. The first season they must be kept growing; in fact, it is better not to dry them off during the second winter. In two and a half years from the time of sowing some of them will bloom, but it will take another year before their merits are fully tested. In the production of the garden varieties of the present day several species have played a part. It has often been a matter of surprise to me that the brightly-coloured *Hippeastrum pratense*, often known as *Habranthus pratensis*, does not

appear to have been tried by the hybridist. The fact that the flowers are smaller than those of most *Hippeastrums* is, perhaps, the reason that we do not see any of its progeny. K. R. W.

EUPATORIUM RAFFILI.

This *Eupatorium* requires indoor culture. There is some mystery attached to its origin, for it was grown at Birmingham Botanic Garden for some years as *E. ianthinum*. Specimens were obtained for Kew, where Mr. Raffil, whose name it bears, noticed differences between it and *E. ianthinum*, and it was eventually described and figured in the *Botanical Magazine* under the above name. It grows

CAMPANULAS IN POTS.

ALTHOUGH the Canterbury Bell is prized by many professional gardeners for pot culture, I doubt if amateurs generally are aware of its value. The first time I saw it blooming, quite early in the year, under glass, I was as much pleased as I was surprised. This *Campanula* is of much service for cutting, as the flower-stems are very stiff and the individual blooms have much lasting power. The seed is sown at the usual time, the only difference being that the young plants are grown on in pots throughout the summer instead of being planted out, so that they come into 6-inch pots by the middle of July, which gives time for the pots to become well filled

being the same as for the Canterbury Bell. There is, however, a great difference between plants that have had high-class culture and those that have been treated in a happy-go-lucky way. This *Campanula* needs a rich soil and strict attention from the time the young plants appear. If not repotted at the right time, but allowed to stand about for a week or two in a semi-starved condition, there will be disappointment, the fine proportions which characterise this Bellflower will be absent, and in this condition it is not worth growing in pots. The varieties of *C. persicifolia* are certainly well worthy of the care involved in pot culture. The double-white is a fine thing, and in a general way cannot be relied on in the open ground; the strain of producing a mass of double flowers seems too great for the constitution of the plant, and in the course of a year or two it dies away. In pots it is otherwise, the watering, feeding, and annual repotting maintaining healthful vigour. Not only is this the case, but the flowers are sheltered from weather extremes which much affect them in the open. I strongly advise your readers to try this beautiful Bellflower in pots; the flowers are as double and finely formed as those of the *Camellia*, and not coarse. Grow the plants in the open air and bring them in for blooming. *C. muralis*, *C. pusilla*, and its white variety are excellent for pots, and may be used where there are window ledges to furnish. They are so hardy that weather changes do not affect them, and they may be kept in the same pots without change of soil for several years. J. CORNHILL.

NOTES AND REPLIES.

Leschenaultia biloba major. — Since Messrs. Balchin gave up their nursery at Hassocks, where they grew this *Leschenaultia* so successfully, it seems to have almost dropped out of cultivation. This is a pity, for the charming blue of its flowers is always admired. The scarlet-flowered *Leschenaultia formosa* seems to have quite disappeared. It was familiar as a specimen plant in days gone by, and was always considered a good test of the cultivator's skill, even more so than its blue-flowered relative, which is by no means the only plant that we miss since the collection at Hassocks was dispersed, for though *Boronia megastigma* and *B. heterophylla* are still grown in considerable numbers, *B. serrulata*, which they used to do so well, is very rarely seen. During a few visits that I paid to the nursery I was very much struck with the richness of colouring to be found in flowers that had developed in the clear, pure atmosphere of the South Downs, compared with those on plants grown a few miles from London. This applied not only to flowers, but to fine-foliaged plants, of which the tricolor *Pelargoniums* and *Acalyphas* were particularly noticeable. — W. T.

Calceolaria Clibrani. — An objection frequently urged against the herbaceous *Calceolarias* is their lumpy and inelegant habit of growth. This cannot be said of *Calceolaria Clibrani*, for it may, I think, be claimed as being the most elegant of all the garden varieties of the genus. It is of a freely-branched habit of growth, and the gracefully-disposed growths are, when at their best, freely laden with soft, yellow blossoms. Another noticeable feature is that in this variety the pouch is more elongated than in most of the other *Calceolarias*, and this, of course, takes off the lumpy character. This *Calceolaria* is readily propagated from cuttings or seeds, and it will grow freely with ordinary

Eupatorium Raffili. From a photograph in the Royal Gardens, Kew.

1½ feet to 3 feet high, and is conspicuous by reason of its handsome foliage and reddish-brown stems. The flower-stalks are reddish-brown and the flowers are lilac. The best results are obtained by cultivating it in a tropical house, but it also succeeds in a warm greenhouse. Cuttings rooted during spring or early summer grow rapidly and form fine plants carrying several large heads of flowers by the following spring, the flowering season being from March to June, although it varies a good deal according to the conditions under which the plants are grown. A good compost consists of three parts loam to one part of leaf-mould or well-rotted manure and one part coarse sand. K.

with roots by the end of the growing time. They should have good loamy soil with a liberal addition of rotten dung or artificial manure of some kind. Keep them in the open until November. A frost or two will do no harm. On the contrary, it will bring them into a state of complete rest. A cool house or frame is the place for them until February, when they may be brought into gentle warmth or be allowed to come on naturally in a cool greenhouse. Plenty of water is needed when they are in full growth, with a dose of liquid manure now and then.

The value of *C. pyramidalis*, the Chimney *Campanula*, has been fully recognised for many years. It is a fine thing either in pots or in the open ground, the treatment

treatment. It is of considerable value for grouping in the greenhouse or conservatory. Its value for this purpose was well shown in some of the groups at the recent Chelsea Show. Beside the name of *Clibranii* it is also known as *C. profusa*. I am not aware of the origin of this distinct and pretty *Calceolaria*, and should be interested to learn it.—W. T.

Tuberose.—These are by many highly esteemed, although some object to their rather over-powering perfume. If potted during May and given a little bottom-heat until top-growth begins the tubers will bloom in August and September. After potting no water ought to be given until growth is visible, but afterwards plenty of moisture is necessary, and as the foliage is liable to be attacked by red-spider and aphids, occasional syringing is needed. After flowering, the tubers are of no further use, and may be thrown away.—KIRK.

VEGETABLES.

NOTES AND REPLIES.

Growing Belgian Chicory (Witloof).—Will you kindly give me some information as to the proper cultivation of Belgian Chicory?—H. E. T. C.

[The Witloof, or Belgian Chicory, succeeds best on ground that has been manured for a previous crop, as contact with fresh manure causes the roots to become forked. The best time to sow is early in May. This should be done in precisely the same manner as Carrots or Beet. The seed germinates very freely, therefore it is best to sow thinly, and so avoid having drawn, spindly plants. Thin out to 9 inches or 1 foot apart as soon as the seedlings have developed a few leaves, and keep them free from weeds afterwards by frequent hoeing. The roots become full grown about the end of October, when they may either be left in the ground and lifted as wanted or be taken up and partly buried in some convenient spot where they will be easily got at during the winter. We favour the latter plan, and lift the whole lot during November. The green tops are twisted, not cut off, and the roots buried just deep enough to cover the crown and no more. As the Witloof is perfectly hardy the roots require no protection beyond that afforded by the soil, only when severe weather seems imminent a little litter shaken over a portion of them will enable them to be got out more readily. Forcing is best done in a Mushroom-house, or any dark place with a temperature ranging between 55 degs. and 60 degs. Strong heat causes the tops to grow more quickly, but they are then not nearly so crisp eating. By keeping the roots buried up outdoors, as indicated, there is no difficulty in keeping up the supply till spring, provided a sufficient quantity of roots is grown with that end in view.]

Cauliflowers.—Continue to plant out for late supplies. Those already planted should be examined, and any failures made good. The hoe must be used frequently between the rows, and they must never be allowed to suffer from want of moisture. Plants that are maturing the curds should have the leaves drawn up and tied over the flowers to exclude light. When large enough, if not required for immediate consumption, the plants may be pulled up and suspended head downwards in a cool shed, where the heads will keep in good condition for several days.

Globe Artichokes.—Where practicable, these should be afforded a copious watering of liquid-manure. A covering of litter may afterwards be placed over the bed in order to retain the moisture for as long as possible. As soon as the Artichokes have been cut, the stems should be removed and the side shoots encouraged to produce crowns later in the season.

GARDEN FOOD.

NOTES AND REPLIES.

Good old fruits.—We notice in the country shops even some old English fruits which colonial people take notice of and esteem, as, for example, the Sturmer and French Crab Apples, and that fine Pear *Bonne de Malines*. We fear our own people sometimes forget these good things in favour of novelties of less value.

The use of salt and sugar.—Not only must we teach children to do with much less sugar, but we must learn to do with much less salt. We add it to nearly all our savoury vegetable food in the cooking, and over and above that, we add still more at the time of eating. No dinner-table is considered complete without one or more salt-cellars; some people take as much as $\frac{3}{4}$ oz. or even 1 oz. a day. It is only those who have discontinued the use of added salt for a time who know how delicious vegetables and other foods can be without it. Even those vegetables that were thought to be almost tasteless unless seasoned are found to have very distinct flavours. People mostly urge that condiments are necessary to stimulate digestion, but, on the contrary, I think they will be found to cause much over-eating. If food cannot be taken without them it is generally a sign that there is something wrong with the digestive system, and so it is better to abstain from food until a natural and healthy appetite is felt. An excess of salt means a great deal more work for the kidneys in separating it from the blood prior to its expulsion. Indeed, it is sometimes thought that some cases of inflammation of the kidneys originate from the excessive use of salt, and what has certainly been proved is that patients suffering from this illness very soon improve if they are placed on a dietary free from added salt.—FLORENCE PETTY.

Rosette Colewort.—A good sowing of this type of Cabbage should be made without further delay. That the plants may be robust and ready for setting out quickly, the seed should be sown on a piece of well-manured ground, and care taken to assist the germination and subsequent growth of the plants by watering whenever it is required. For convenience when drawing the plants, the seed should be sown in drills 9 inches apart. Coleworts are useful for planting after early and second early Potatoes, and may where space is restricted be put out 1 foot apart each way.—A. W.

SOME OF MRS. EARLE'S RECIPES.

NUT CUTLETS.—Boil 2 ozs. butter in rather less than $\frac{1}{2}$ pint of milk. Add 3 ozs. of dried bread-crumbs (or brown bread-crumbs). Cook till it does not stick to the pan. When cool add 2 ozs. ground Walnuts, Almonds, or Barcelona Nuts, seasoning to taste, and a little chopped Onion or Chives. Mix thoroughly and shape into cutlets or balls. Roll in flour, or in egg and bread-crumbs, and fry in butter or bake. Serve with Tomato sauce, Walnut gravy, or, for children, with bread sauce. If the same dish is prepared with white bread-crumbs, and a little good melted butter sauce used for mixing, it looks and tastes very like chicken croquettes.

MACARONI AND CHEESE PATTIES.—Take 1 oz. macaroni well boiled, cut very small, and add one large tablespoonful of grated cheese and the same of cream or Nut butter. Season with salt, pepper, and mustard if liked. Make some short paste; roll out thin and line patty pans. Fill with the mixture and cover with paste. Bake a light brown. Instead of patty pans, the paste can be doubled over the mixture and fried as fritters if preferred. Butter and milk can be substituted for cream, and it is quite good without either. But in that case the macaroni should be rather moist and the cheese fresh and soft.

BRAISED ONIONS.—Peel large or medium sized Onions in warm water to prevent the volatile oil from affecting the eyes; place them in a baking dish with butter enough to baste them well, and bake 3 hours, when they will be brown and tender. Remove them on to a serving dish, pour hot water into the baking tin, and with a wooden spoon rub off all the dark-brown baked juice, thickening, if liked, with a little flour, in which case the tin must be placed over heat enough to boil the gravy and cook the flour. Pour over the Onions and serve. This is a delicious dish which puzzles meat-eaters, as they think they are eating a rich meat sauce.

AN EXCELLENT VEGETABLE SOUP.—Take 2 Carrots, 2 Onions, 2 Turnips, a little Spinach, Lettuce, Endive, and Sorrel. Tie up together a sprig of every sort of herb you have in the garden. Boil all in water. When the hard vegetables are cooked, take out the sweet herbs, rub the whole through a fine sieve, make it not too thick by adding the water the vegetables were boiled in, add a little butter, pepper, and salt, and serve hot.

CHOU BRAISE.—Take a nice spring Cabbage, split it, and wash in salt and water, put it in a saucepan of boiling water for ten minutes. Take it up, drain well on a sieve, put it into a casserole pot for one hour to braise with a little butter, and pepper and salt to taste, but no stock or water.

CLEAR STOCK.—This is made of the water in which vegetables, macaroni or Spaghetti have been boiled—about 2 quarts. Early in the morning cut up, rather small, all kinds of vegetables (except Potatoes and Cabbage) in season; the stalks, outside leaves, and peelings may all be used. Let these boil slowly all day in a 2-quart saucepan, adding a little more of the cold vegetable or macaroni water to make up the necessary amount. Skim every 20 minutes for about 2 hours. About 1½ hours before dinner strain the soup through a fine sieve, and leave it to cool. If too light in colour add a little Onion juice fried in butter; this stock is a good foundation for all sauces, and the greatest improvement to many dishes. It is the French *Pot-au-Feu* without the meat.

VEGETABLE POT-AU-FEU.—Cut up into small pieces as many vegetables as you have—Carrots, Celery, Turnips, Cauliflowers, Onions, or any other vegetable. Fry them in butter till browned. Put in a saucepan with water. Add a handful of tapioca, and let it simmer gently all day. Skim occasionally; strain and serve with sippets of toast.

STOVED POTATOES.—Peel the Potatoes and cut into medium slices. Heap up a quart saucepan with them. Put in salt and pepper to taste. Cut the Onions and put into the saucepan pouring over all a gill of cream. Put lid on tight and cook on slow fire 20 to 30 minutes, or till Onions and Potatoes are quite done and cream nearly all boiled up.

DATE PUDDING.—Wash dates quickly in hot water; dry, stone, and chop them; mix with double their weight of bread-crumbs, and a little sugar. Add skim milk or weak Plasmon solution till of pudding consistency, steam 2 hours in buttered basin. Ground Nuts and grated Lemon peel may be added, if liked, or raw coarse oatmeal, and soaked tapioca, with a little flour, may be used instead of the bread-crumbs.

STEWED CHESTNUTS.—Slit the skins of the Chestnuts, and put them into cold water. Bring to the boil, keeping lid tight, and cook about ten minutes. Lift out a few at a time and remove both outer and inner skins. When all are done put them into a clean saucepan, and cover with milk or milk and water. Stew slowly till the Nuts break and are coated in a smooth creamy sauce. Time 1 to 2 hours. An old saucepan used for nothing else should be kept for blanching them, as Chestnut skins discolor badly.

POTATO SALAD.—Boil the Potatoes in their skins at least 2 hours before dinner. Cut them in slices $\frac{1}{4}$ inch thick; put in a china bowl with 1 to 2 soup ladles of hot broth or vegetable stock, and let them soak and remain tepid till dinner-time. They should so absorb the broth that they look dry. When served mix with a thin mayonnaise sauce, and surround with young Lettuces previously dressed with oil and vinegar. They can be dressed with Beetroot, Cucumber, or Tomatoes.

TREES AND SHRUBS.

THE PEARL BUSHES.

(EXOCHORDA.)

THE Exochordas are old world shrubs belonging to the Rose family, and closely related to the Spiræas. They are few in number, but all are attractive, and as they are easily grown they should be represented in every collection of shrubs. All are white-flowered and bloom in May or early June, the flowers, as shown in the accompanying illustration, being much larger than those of any of the Spiræas. A sunny position is desirable, and the most suitable soil is well-drained loam. Propagation can be effected in summer by means of cuttings of half-ripe shoots inserted in sandy soil in a close frame, whilst regular pruning is not required. The two best known species are E.

It promises to be an improvement on E. macrantha, for its flowers are each about 2 inches across and the racemes large.

E. MACRANTHA, the subject of the accompanying illustration, is a hybrid raised by the late M. Lemoine, of Nancy, between E. Alberti and E. grandiflora, and in point of free flowering qualities it is superior to either parent. In fact if one kind only is required there should be no hesitation in selecting the hybrid. Its hybrid parentage is noticeable in the stamens, for the numbers are unequal and the groups of stamens in different flowers are of unequal number. D.

THE MOCK ORANGES.

(PHILADELPHUS.)

THE Mock Oranges, or Philadelphuses, blossom after the bulk of the spring-flowering shrubs is over, and may be considered as the forerunners of the

Lemoine, of Nancy, a typical one being P. Lemoinei.

The Mock Oranges thrive in ordinary garden soil, but show a partiality for good loam. They are gross feeders, and where the soil is poor it is a good plan to apply a good surface dressing of well-decayed manure now and then. Although they will grow in semi-shade, an open position is desirable, and it is advisable to so arrange their planting that the roots of vigorous-growing trees are not likely to interfere with them. The strong-growing species rarely need pruning, while the dwarf P. microphyllus can also be left unpruned for years, but the hybrids, of which P. Lemoinei is an example, give the best results if pruned annually. This pruning should be carried out as soon as the blooms fade, and the old flowering wood should be cut away to where vigorous young shoots are being formed. In many

Flowering shoots of Exochorda macrantha.

Alberti and E. grandiflora, which have much in common and are rather difficult to tell apart when out of flower. When in flower, however, their identity is easily established by means of the stamens, for whilst E. Alberti has twenty-five stamens in groups of five each, E. grandiflora has fifteen stamens in groups of three each.

E. ALBERTI is a native of Turkestan and is sometimes met with under the name of E. Korolkowi. It grows up to 15 feet high and produces racemes of flowers 3 inches or so long.

E. GRANDIFLORA grows almost as tall, and blooms more freely, both individual flowers and racemes being larger than those of E. Alberti. It is from Northern China and has been in cultivation since 1849.

E. GIRALDI is quite new to cultivation in this country, for it was only introduced from China about seven or eight years ago.

smaller, summer-flowering set. Moreover, they are very beautiful when in bloom, and the majority are fragrant, whilst there are few gardens where one or more species or hybrids cannot be grown. In most cases the flowers are white, but in one or two instances the petals have purple blotches at the base. A good deal of variation in habit is noticeable, for there are bushes of all sizes, from the large-growing P. grandiflorus, which sometimes grows 18 feet or more high, to the dwarf P. microphyllus, which is sometimes fully developed at a height of 2 feet. They are natives of S.E. Europe, Asia Minor, China, and the United States of America. Some have been introduced many years, while a few have made their appearance during the present century or last decade of last century. In addition to the species there is a very beautiful series of hybrids raised by the late M.

instances they can be removed to the ground line. Their removal allows the full energy of the plant to be concentrated upon the production of vigorous young shoots, which, in the course of the summer, grow from 2 feet to 3 feet long, and bloom from end to end the following June. Propagation is easily carried out by means of young shoots 4 inches or 5 inches long inserted in sandy soil in a close frame during June and July. The commonest species is

P. CORONARIUS, the Mock Orange or Syringa of gardens. The latter name, by the way, is unfortunate, for it is also the scientific generic name of the Lilac, and it frequently leads to confusion amongst people who are not conversant with the peculiarities of plant names. P. coronarius is a very free-flowering bush, sometimes more than 12 feet high, with a considerable spread, its fragrant,

creamy-white flowers being each over 1 inch across, and borne in good-sized racemes in June. It is a native of S.E. Europe and Asia Minor, and appears to have been grown in England since the earliest recorded days of horticulture. There are several varieties, some with double flowers, some with variegated leaves, and one of dwarf habit, but all are inferior to the type.

P. GRANDIFLORUS, a vigorous shrub introduced from the United States upwards of a century ago, is also a desirable bush. Sometimes over 18 feet high, it grows into a large, wide-spreading bush, and bears pure white flowers, which are each over 2 inches across. Those who find the scent of the common Mock Orange too powerful should plant *P. grandiflorus*, for its flowers are almost, if not quite, scentless. The variety *laxus* is a peculiarly free-flowering variety, the blooms rather smaller than those of the type and the branch system looser.

P. FALCONERI is another large-growing bush, and very beautiful when at its best, but, unfortunately, it cannot be relied upon to bloom so freely as the others already mentioned. Its pure white flowers are each about 1½ inches across, and less strongly scented than those of *P. coronarius*.

P. LATIFOLIUS is another strong-growing species of the *P. grandiflorus* type, in fact it is sometimes called *P. grandiflorus* var. *floribundus*. It grows quite as tall as *P. grandiflorus*, and its pure white flowers are very similar in appearance. It, however, blossoms even more freely than that species, and is well worth planting as an isolated bush.

P. MAGDALENÆ grows about 6 feet high and forms a rather dense mass of slender branches. It is a native of W. China and was introduced to France about 1895. The flowers are white and each about ¾ inch across.

P. MICROPHYLLUS is a dense bush from 2 feet to 4 feet high, with small, twiggy branches, tiny grey-green leaves, and powerfully fragrant white flowers. It is an excellent little bush and was used by M. Lemoine as a parent for some of his best hybrids. *P. microphyllus* is a native of W. North America.

P. MEXICANUS is a rather tender species from Mexico, suitable for the south-west counties, but not hardy about London. It grows 6 feet or 8 feet high and bears large, handsome, fragrant flowers, each about 2 inches across. In the variety *Coulteri* the petals are blotched with purple, and by using it as a parent a hybrid with purple-blotched flowers has been raised. This is called *purpureo-maculatus*. It resembles the *Lemoinei* group in habit and in size of flowers, but is rather less hardy than

P. LEMOINEI, which, when left unpruned, grows about 4 feet high, but plants pruned annually are usually about 3 feet in height, the majority of the hybrids being of similar growth. *P. Lemoinei* is very free flowering, and its variety *erectus* may be included as one of the most useful twelve flowering shrubs. Other useful hybrids are *Avalanche* (very large pure white blossoms), *Fantasie* (also with very fine white flowers), *Boule d'Argent* (double white), *Pavillon blanc* (flowers white and large), *Rosace* (flowers semi-double, each 2 inches to 3 inches across), and *Virginal*, with double flowers. The hybrids are usually seen at their best when planted in groups and pruned annually. In unpruned plants the branch system is inclined to become very dense and the flowering branches short, the graceful habit which is such a charm of pruned plants being thus lost. D.

GARDEN PESTS AND FRIENDS.

FRUIT-TREE PESTS IN JUNE.

CATERPILLARS of the winter moth type, larvæ of the codlin moth, and those of various sawflies are amongst the destructive visitants of June and July. Parasitic fungi, too, like those that cause scab in Apples and Pears, as well as numerous mildews, are often aided by weather conditions until quite late in the season, so that no relaxation of vigilance is safe during the whole of the summer. The application of poisonous compounds to foliage attacked by caterpillars has proved to be an efficient means of destroying the pests, and provided ample time is allowed before the fruit is to be used there is no danger to the consumer. Foremost amongst the substances employed is

PARIS GREEN, an aceto-arsenite of copper, obtainable both as a powder and a paste, the latter being preferable in many respects. Special preparations are now sold by reliable firms that can be used with greater safety as regards the operator, and with little risk of leaf scorching. The addition of lime is also found to decrease the latter danger, and a well-proved formula is 1 oz. each of Paris paste and lime to 10 gallons of water, mixed gradually and thoroughly in a wooden cask or tub. A good spraying apparatus must be employed to ensure the constant agitation of the liquid while being distributed on the foliage. Another substance which has given good results with little leaf injury is

LEAD ARSENATE, and this also can be had as a paste. Directions are sometimes given to growers to save expense by making the arsenate themselves from acetate of lead and arsenate of soda, but this is not advisable, as many cases of serious leaf scorching have been due to such amateur attempts, and an otherwise useful compound has been unfairly condemned. Double the quantity of the lead arsenate paste can be used as compared with Paris green, and even larger proportions have been employed, but 2 ozs. to 3 ozs. to each 10 gallons of water generally suffice. Both these substances are of especial value against caterpillars of all kinds.

PARAFFIN EMULSION when carefully prepared has been found a useful summer application for pest-troubled fruit-trees, particularly against aphides, American blight, sawfly larvæ, and the smaller caterpillars or grubs. The best qualities of lighting paraffin should only be used, and soft soap is the safest substance to use with it. A good dressing can be made with 1 lb. of soft soap and ½ pint of paraffin to 5 gallons of water. Dissolve the soap in hot water, gradually add the paraffin, constantly stirring, and then mix with the full quantity of soft water. When mildew is also present the addition of 2 ozs. of potassium sulphide is helpful.

TOBACCO in many forms is most effective against aphides and similar enemies, and such preparations have the advantage that they cause no leaf injury. Nicotine itself, though costly, is preferred by many experienced men, such a small quantity of the pure extract being needed that the expense is not great. About 1 oz. to 10 gallons of water is usually sufficient, but repeated dressings may be required.

QUASSIA EXTRACT is a safe and useful dressing, especially with the addition of soft soap at the rate of 4 ozs. to 6 ozs. to each gallon. Few care for the trouble of boiling Quassia chips when the extract can be purchased ready for use. While destructive to aphides and small caterpillars, this also prevents sawfly attacks,

especially when ½ pint of paraffin is added to each gallon.

HELLEBORE POWDER is still preferred by many against Gooseberry caterpillars, and if dusted over the bushes freely in early morning it effectually checks an early attack. As a fungicide for ordinary use nothing more efficient can be recommended than the best

BORDEAUX PASTE, a preparation of Bordeaux mixture especially suited for summer spraying of fruit-trees, and it can be proportioned in strength to the hardness or delicacy of the foliage of different kinds.

POTASSIUM SULPHIDE is employed for mildew attacks, but alone it is rather uncertain, and it is wise not to exceed ½ oz. to each gallon of water.

All spraying is best done early in the morning or late in the evening, the latter being preferable. Calm weather should be chosen, both to ensure efficiency and to avoid waste of the washes used. In most cases also it is advisable to give at least two sprayings at intervals of two days, and this gives the chance to increase the strength of the application if necessary. The best form of knapsack sprayers should be used for all small trees and bushes, seeing that the machines are kept in good working order.—R. L. C. in *The Field*.

NOTES AND REPLIES.

Red-spider on Gooseberry-bushes.—I enclose some leaves from a Gooseberry bush. Would you kindly say whether there is evidence of some disease, and, if there is, how it can be cured? Also, can you tell me if there is any strong-smelling liquid that can be used to keep birds from fruit, and, if so, what and how applied?—W. E. P.

[Your Gooseberry bushes have been attacked by red-spider. Spray them with a solution of paraffin emulsion, to every three gallons of which add 1 oz. of sulphide of potassium (liver of sulphur), and be sure that the undersides of the leaves are sprayed, as it is there that the red-spider is. Merely wetting the upper sides of the leaves will be of no avail. The only way to save your fruit from the attacks of birds is to net the bushes.]

FERNS.

REPOTTING FERNS.

I do not know who is your Fern authority, but recently I notice that his remarks in some cases betray a lamentable ignorance of practical facts. Last week, for instance, he stated that to obtain symmetrical, handsome growth, Ferns in pots should be turned about so as to prevent them growing towards the light, etc. This week he says that "Ferns should never be disturbed while in a dormant state; it is much better to wait until they have started into active growth." The fact is that as the fronds during growth will grow in such a way as to expose their fronds to the best advantage as regards exposure to light, unless the light be an absolute top-light, any shifting results in a few hours in a readjustment of the growing portions, which means unnatural curvature of main and secondary stems and distorted growth generally. I therefore have always advised the insertion of a label or other indication, so that if for any purpose the Fern is shifted it may be replaced in its former position and aspect as regards the light. In the second case, absolutely the very best time to divide and deal with Ferns generally is towards the end of the dormant period, but well before actual growth begins, since after the rest their constitutions are invigorated and there is no risk of damaging the rising

fronds or incipient roots. I speak, as you probably know, from long experience, and because I think it a pity that precisely opposite instructions should, as in this case, be given by presumed authorities.
CHAS. T. DRUERY.

[We have always been taught that the best time to repot Ferns is just as they are well on the move. This is the plan we have always followed, and have had no reason to change it. It stands to reason that when a plant, be what it may, is repotted, it should be starting into free growth for the reason that if shifted when dormant the roots are inactive, and it is more than likely that owing to this inactivity the soil will, especially if over-watered, become sodden and thus imperil the health of the plant. If the plant is in active growth the roots, if care as to watering is taken, very soon permeate the fresh material.]

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

THE ALPINE FLAX.

I AM a great lover of the blue Flax. I forgot to grow this little alpine Flax,

The Alpine Flax (Linum alpinum).

which is free in habit, though dwarf, and delicate in colour. A gem among rock plants I call it, and it appears to be easily grown. Native of Austria. W.

Calceolaria polyrrhiza.—This likes a shady situation, not too dry, and when in congenial quarters spreads quickly by means of underground stems into a large clump. I grow it low down in the rock garden under the shelter of a big rock, where it gets the early morning sun and is shaded for the rest of the day. It does very well in a light sandy soil with a fair proportion of lime in it. The flowers, borne profusely, are of a deep yellow with little brown dots over them, and are carried singly on stems about 5 inches or 6 inches high. It seems quite hardy.—N. L.

Erodium corsicum.—I think this is one of the best of the genus. It is of a dwarf, compact habit, with soft green, rounded leaves, and neat flowers of a pleasing shade of deep pink beautifully veined. Like most of its relatives, a hot, dry position seems to suit it best, in sandy, limy soil.—W. O. C.

Erodium trichomanefolium.—I am not very fond of the Erodiums, but they are useful for a hot, dry situation, and this species has very pretty, finely-cut foliage. It blooms freely, and the flowers are beautifully veined, but of a rather hard shade of pink. It seeds freely and can easily be raised in this way.—W. O.

FRUIT.

EARLY PEACHES.

The fine, sunny weather of the past week has been welcomed in these times, when it is imperative to economise—particularly in regard to fuel—by all fruit growers, as not only can the structures be liberally ventilated and suitable temperatures maintained, but sufficient sun-heat can be bottled up, so to speak, in the afternoon to render the employment of fire-heat during the night superfluous. If the temperature should fall lower than is perhaps desirable, at night or early morning, such leeway can always be made good in the day-time by keeping the temperature ranging between 80 degs. and 85 degs. and closing in time to ensure a rise of 3 degs. to 5 degs. more. Accompanied by a liberal syringing, the fruits, when this method of treatment is pursued, swell rapidly and soon reach the ripening stage, indication of which is given by the skins of the fully-exposed fruits beginning to put on colour. When this becomes general a gradual modification of treatment is necessary. Overhead syringing has first to be dis-

effected. Pegs made from the twigs of worn-out Birch brooms, or Bracken, or galvanised wire for holding the runners in position until rooted should, to the required number, be made ready beforehand. When young plants are not set out purposely for supplying runners, the needful quantity should be obtained from the youngest, preferably those set out last autumn, of the fruiting plants.—G. P. K.

FRUIT TREES FOR NORTH WALLS.

Will you be good enough to let me know what fruit-trees, apart from the Morello Cherry, are best for a north wall?—A. S. E. SEDGWICK.

[In most gardens walls having a northern aspect are used for the cultivation of the Morello Cherry, which, we think, is a pity, as in many parts of the country other fruit trees, such, for instance, as choice, late dessert Plums, succeed admirably on north walls, to say nothing about Red and White Currants and dessert Gooseberries. Where Morellos are in demand as late as they can be had, it is then necessary to accord the trees a position where they will be shaded from the sun during the hottest part of the day, and such a position with the necessary amount of shade they experience when grown on a north wall. For the earlier supply, Morellos may just as well be grown as bushes as not, for they bear heavy crops grown in this form, while the individual fruits are quite as large, and they hang for a long time if netted over. If this is done, the space they would otherwise occupy on the walls can be utilised for the growing of Plums as indicated above. Those who have to provide a large and varied dessert through the autumn months know full well the value of having a few trees of choice kinds of dessert Plums to fall back on when indoor fruits other than Grapes begin to become scarce. Such kinds as Coe's Golden Drop, Jefferson's, and Ickworth Impératrice will hang in good condition quite as long as the Cherries if covered with coarse muslin or very thin tiffany as a protection against birds, wasps, and flies while they are ripening.

No special culture is needed for growing Plums on such a position, and, as a rule, owing to their flowering later than those out in the open and those on walls having warmer aspects, they escape the spring frosts and invariably set good crops of fruit. Where north walls are of considerable extent, and the climate suitable, we would strongly recommend that a portion of the same be devoted to the growing of dessert Plums for late autumn supply. Gooseberries are also a very profitable crop when grown on north walls, and the fruit may be had much later than when grown on bushes. The best way to grow these is as cordons with from three to five branches, which should be trained perpendicularly in the same manner as upright cordon Pears or Plums. Currants of both Red and White varieties bear most profusely grown in the same way, and come in useful after the fruit on the bushes out in the open garden has been gathered. Where autumn-fruiting Raspberries are grown, these late Currants are doubly useful, as they can then be utilised for tart-making in addition to being useful as an adjunct to the dessert. We do not reply to queries by post.]

Summer pruning.—Continue summer pruning at short intervals, pinching some shoots, and tying in others to the trees, to replace worn-out branches. On no account retain superfluous shoots to the detriment of those intended to bear fruit next season. Some shoots almost invariably take an undue share of the sap, but by timely pinching with the finger and thumb the proper balance may be maintained.

pensed with, the requisite amount of moisture being obtained by the damping of the paths and surface of the borders. This, in turn, must be reduced to a minimum as the maturation of the fruits progresses, and finally withheld when an aroma is given off, which indicates that the finishing stage has been reached. Warm, dry air is essential for both finish and flavour to be satisfactory, and a chink of air should be left on at the top of the house throughout the night. The approach of the colouring stage is the signal to give the last stimulative watering. After this, plain water, if a further supply is needed, is given. For home consumption the fruits should be allowed to become ripe, not dead ripe, before gathering them. A. W.

Layering Strawberries.—Preparation for layering the required number of runners for forcing and for making new plantations should now be made. Layering into 60-sized pots filled with loamy compost which has been enriched with spent Mushroom dung or well-rotted manure is really the best method. The pots can be prepared on wet days, and when the runners are sufficiently advanced in growth the layering can be quickly

THE WEEK'S WORK.

SOUTHERN COUNTIES.

Tomatoes.—These have made a good start and require all side growths pinching back close to the stems. Now that new roots are pushing out in all directions a little liquid manure will be added to the water to stimulate and tide the plants over the next week or two while chilly nights are likely to be encountered.

Autumn Cauliflowers and Broccoli.—Advantage should be taken of the ground being moist to get both of the foregoing planted. Ground in good heart is necessary, particularly for the first-named, and good heads must not be expected from poor soil. If liquid is plentiful, amends can be made in the latter case by a free use of it after the plants start growing. From 2½ feet to 3 feet is none too great a distance for the rows of Cauliflowers to stand asunder, and the plants may be from 2 feet to 2½ feet apart in the rows, according to the fertility of the soil. Broccoli may be planted from 2 feet to 2½ feet apart each way.

Cabbage.—Plants to supply heads for cutting at the end of the summer should at once be planted. Any of the main crop sorts answer for planting at this date, Enfield Market being a good one if good-sized hearts are required. The plants should be set out at least not nearer than 18 inches each way.

Savoy.—Some do not care for Savoy Cabbage until the heads have been subjected to the influence of frost, but the small-hearted early varieties form a welcome change in late autumn, and are by many much appreciated. They do best on firm, heavy ground, and these early sorts can be planted from 15 inches to 18 inches apart all ways.

Early Cauliflowers.—These are now turning in. As soon as the crop is cleared, the site, if lightly dug with a fork, will do for Celeriac without any further preparation. Celeriac, unlike Celery, is planted on the surface. Lifting with a good ball is essential, and a good soaking of water should be given prior to lifting, and again when planting is completed. Afterwards water must be applied unstintingly during dry weather. A surface mulch of some description, though not imperative, lessens the need for watering frequently.

Endive.—Seed of both the Green Curled and Broad-leaved Batavian varieties should now be sown in the same way as for Lettuces. Both are in much request for salad-making in autumn.

Flower beds.—The hoe should be run through the surface of the soil both to aerate it and to destroy weeds in an incipient stage. Owing to the heavy showers of rain there has been no necessity for artificial watering, and the plants, as a result, will start away all the quicker. Unless necessary to have plants in bloom as early as may be, all flowers for the present should be picked, which will strengthen and induce them to grow more strongly. Heliotropes, Petunias, Verbenas, etc., should be pegged down at once, so as to cover all bare spaces.

Specimen plants for lawns.—These, having been thoroughly hardened off, will now be stood in the positions they are to occupy during the summer. When arranged, the surface of the soil will be mulched with old Mushroom dung after it has been passed through a ½-inch sieve. To maintain the plants in a free-flowering condition judicious feeding is necessary, liquid manure and Clay's fertiliser being two excellent stimulants for the purpose. In hot weather watering needs to have attention daily—i.e., in the morning and late afternoon.

Herbaceous borders.—These require looking to frequently, otherwise wind and rain soon spoil their appearance. Spray saved when trimming Pea sticks will be used as far as possible for supporting all subjects for which it is suitable, as a much more natural appearance results than when a quantity of stakes is used. If carefully worked in among the plants, it is quite unobtrusive, and forms a most effectual support. All bare spaces should

be well hoed and the roots kept well supplied with water in dry weather. Single Asters are most effective in autumn, and look best when planted in a border by themselves, arranging the colours so that a harmonious whole is secured.

Border Chrysanthemums.—These are growing vigorously, and promise to make very fine plants by the end of summer. Their chief requirements for the present are to keep the soil frequently stirred and not to let the roots feel the want of water.

Michaelmas Daisies must now be looked over, when the weakest and surplus shoots should be pulled out, as it is a mistake to allow all growths which push up to develop.

Show and fancy Pelargoniums.—As these pass out of flower the plants should be stood outdoors in full sun for the wood to become thoroughly ripened. When this has taken place, propagation can then be effected by cuttings made from the best ripened growths. These should be potted singly into thumb pots, using a sandy compost and placing a dash of sand at the base of the cuttings. They strike quickly in a Cucumber frame. When a sufficiency of cuttings has been secured, the plants should be pruned back, placed in a cold frame, and kept on the dry side until they begin to break freely, after which they should be shaken out and put into pots one or two sizes smaller. To enable this to be done a certain amount of root reduction is necessary. A later batch now in bloom requires careful attention in regard to watering, in keeping the house cool, and the flowers shaded from direct sunlight.

Indian Azaleas.—These, having completed their growth and set their buds, will now be moved outdoors and plunged in a bed of ashes, which is partially shaded from the mid-day sun by a wall some 10 feet in height. However carefully the syringing may be done, some few thrips are almost sure to be present, and these are best dealt with when the plants are moved to the open. For this reason their presence was no longer desirable in the vinery, where they were put to complete their growth. A. W.

MIDLAND COUNTIES.

Apricots.—Chiefly owing to the inclemency of the weather while the trees were in bloom the Apricot crop in these gardens is a very thin one. This condition of the trees is accompanied by a stronger wood growth than usual, which is not favourable for the prospects of a good crop next season. All strong shoots, especially those which form a right angle with the wall, are pinched at the fourth leaf from the base, and such of the strong shoots as it is necessary to retain are pinched at the point in order to check development. All superfluous ones are removed entirely, leaving only those for which there is space—at 4 inches to 6 inches apart. An occasional syringing with clear water in the early morning or evening will keep the trees in good order. Where a good crop of fruit has been secured the final thinning should now take place.

Peaches and Nectarines opened their flowers later than those of the Apricot, and thus escaped the severe weather, and the trees are carrying a bountiful crop. The final thinning of the fruits will shortly be carried out. Tie in and regulate the shoots as they increase in length and pinch the laterals. The trees have been afforded a copious watering. Poorness of the soil and dryness at the roots are often the cause of the trees being badly attacked by insects or causing them to be unhealthy.

Fig-trees on a south wall will now be freely disbudded to prevent the shoots becoming overcrowded, and in order that the fruits may be fully exposed to the light and air. Remove the extra strong shoots and retain those that are short-jointed, as these will ripen better and prove most fruitful. Remove sucker growths from old trees and thin the fruits if necessary, but do not stop the shoots. Fig-trees out-of-doors require very little, if any, syringing.

Early Peach-trees.—As soon as all the fruits are gathered the trees will be relieved of

useless wood by cutting away such as has produced fruit and can be replaced by young shoots. By so doing the wood retained for next season's crop is given a better chance to develop and ripen. Give the trees a thorough soaking of clear water, also well wash the foliage every afternoon with the hose-pipe or garden engine to keep it clean. If the trees are badly affected by red-spider, syringe them two or three times with an approved insecticide. It is essential to keep the foliage healthy as long as possible. All ventilation possible should be admitted night and day. Trees in successional houses where the fruit is swelling must be well supplied with water, and where the trees are carrying a heavy crop give liquid-manure. Make free use of the syringe as long as possible to keep down red-spider. As the fruits approach ripeness, ventilate freely, leaving the top ventilators open a little all night.

Early Vinery.—All the Grapes having been cut, the border, if dry, should be given a thorough watering and the foliage should be syringed two or three times a week with clear water. Should red-spider be present on the leaves, spray with insecticide late in the afternoon. Early Muscat Vines on which the fruit is ripening require a good amount of fire-heat on dull, cold days. Attacks of red-spider must be checked, but insecticides must be used with great care as the foliage of Muscats is more easily injured than that of other Vines. The leaves are also subject to scorching after a period of dull weather. The glass may be shaded by spraying a little whiting over the roof. The inside border must be watered if necessary, but extremes of either wetness or dryness must be avoided, especially at the present stage when a check would be highly injurious to the crop.

Dianthus, for a display next summer, should be sown now in an open situation, covering the seeds lightly and shading till the seedlings appear.

Gladioli are apt to get injured by rough winds. When the growths are about a foot high staking must be attended to. When planted in groups on the borders it is best to give each a separate stake, but if planted in rows a stake placed at each end with two rows of soft twine carried across, to which the flower-spikes may be secured, will be sufficient.

Early-flowering Chrysanthemums.—Plants which were put out in May are growing freely. The roots are kept well supplied with water, and a mulch of short manure afforded. A vigorous syringing occasionally with clear water encourages strong, clean growth. Should aphides appear on the plants they must be syringed with an insecticide. I spray the plants at regular intervals with Quassia extract as a preventive of this pest.

Broad Windsor Beans.—Late sowings should be heavily mulched and kept well supplied with water or the yield will be poor. Stop the growths of mid-season sowings immediately a fair amount of bloom can be seen, as the majority of the flowers will fail to set if the shoots are not stopped.

Beetroot.—The main crop should be thinned to 9 inches apart. Hoe the ground frequently between the rows, taking care not to injure the roots. A sowing of Egyptian Beet made now will provide good-sized roots for use during the winter and spring.

Endive.—Seedlings from the first sowing will be transplanted into rows, and another sowing made. If the ground is dry give the drills a good soaking of water before sowing the seed.

Lettuce.—Tie up the varieties of Cos Lettuce as they become fit, as this will greatly improve the hearts. Continue to plant out at intervals for succession. Mustard and Cress are sown every week or ten days in a shady place, covering the seeds with a double thickness of mats until they have germinated.

F. W. GALLOP.

SCOTLAND.

Flues, etc.—Following the usual custom now that fires are not wanted, all the heating apparatus has been examined. It always pays to overhaul the boilers, etc., at this time, as any deficiencies can much more readily be detected and put right than when the fires are

kept on. All flues, soot-boxes, valves, and so forth were seen to, the water run off, and the boilers refilled. Afterwards, towards night, the fires were lit, and the water driven fairly rapidly through the pipes in order to ascertain that everything was in proper working order and ready for immediate use when required. One detail is at times overlooked. I refer to the chimney cans, which are sometimes almost closed up with sooty deposits. If these are scraped off a good draught is ensured, and there is no danger of back draughts.

Hard-wooded plants.—The time has now arrived when hard-wooded plants—not now so popular as their merits deserve—can be safely removed to the open air to mature their growth. Naturally, they ought to be placed in a sheltered and sunny spot, protected from winds which might yet do damage. If possible, these plants should be assembled in one place, and, if the watering is in reliable hands, there is no reason why they should not be partly plunged. Should any of the plants need repotting, now is the time to attend to it. These plants, however, after having been repotted may with advantage be put for a time into a cool house or pit until the roots get to work. Any pinching or pruning necessary to aid or to induce symmetrical form can now be attended to as required. Keep the syringe at work among Azaleas, as the leaves are apt to suffer from the attacks of thrips.

Roses.—A look round was given to all Roses in the course of the week. Although the spring was cold and inclement, yet the recent weather conditions have evidently suited Roses, the growths being exceptionally clean, healthy, and vigorous. The surface of beds and borders, rather beaten down by the recent rains, was again stirred up with the hoe. Previously the soil received a dressing of bone-meal, superphosphate of lime, and sulphate of ammonia, the last being added at the rate of one part to two parts of the others. This makes a very useful mixture. Roses on south walls are numerous, these being chiefly Gloire de Dijon, Rêve d'Or, and Mme. Berard. A number of young plants of Thalia, Dorothy Perkins, and Hiawatha intended for forcing next spring have been attended to. These are very useful varieties for the purpose mentioned, and they can be well done in 6-inch pots.

Planting out.—After the bulk of planting out has been done there usually remain a few odds and ends which require places. Such things as *Aloysia citriodora*, the Apple-scented Sage (*Salvia rutilans*), and similar things may now be put into their summer quarters. Fortunately, owing to the dripping weather lately experienced, there has been no need for artificial watering.

Cucumbers.—In whatever manner Cucumbers are grown—in houses, pits, or frames—abundant ventilation will be necessary. It is quite safe to allow the thermometer to run up to 100 degs., but copious damping down must be allowed when this temperature is reached. The moisture so obtained, combined with the heat, results in rapid growth, and, apart from that, it keeps down insect pests.

Stove.—One of the most charming things for winter flowering is *Gesnera cinnabarina*, and some of its varieties. If not already attended to, let the corms be shaken out, repotted, and started. It is usually understood that peat is needed to ensure the successful cultivation of the *Gesnerads* generally. It is a wrong theory, as I have grown them all well without peat. My compost is loam, well rotted leaf-mould, and well-decayed Mushroom-bed manure in equal proportions, with sufficient sea-sand to make the whole porous. The occasionally trying *Saintpaulia ionantha* succeeds well in that mixture. Cuttings of *Poinsettias* can be taken as they become available. I may, of course, be wrong, but I think that *Poinsettias* are not at all worth the trouble which they entail. Fires are now stopped, early closing being resorted to in order that the heat may be conserved as far as possible.

Tomatoes, now making rapid progress, are being attended to from day to day. Artificial fertilisation is being given to the later plants in bloom under glass. The earlier lots have been top-dressed with a mixture of loam, bone-

meal, and superphosphate of lime in equal proportions, with the addition of a little soot.

Orchard-house.—The trees must be well nourished. Any niggardly feeding now may result in an unsatisfactory crop, not only in bulk, but in finish. The syringe is indispensable, and if, as will happen, aphids appear, I find nothing more useful than Tobacco powder. Ventilate freely both by day and by night.

Cold frames.—Where these can be moved they may now with advantage be turned so that they will face the north. Such a position will be found useful for *Cyclamens* and *Primulas* especially. Ferns of the *Pteris* family are at home under such conditions, and *Cinerarias* will appreciate such a situation.

Hardy fruit.—Occasionally, black aphid attacks Morello Cherries, and in such a case no delay ought to occur in disposing of the pest. When such an outbreak occurs in normal times, I believe in douches of clear water through the syringe, but when, as at present, labour is scarce—skilled labour, that is—I find that a mixture of Fowler's nicotine and carbolic soap, with the addition of a small proportion of flowers of sulphur, acts well. The same formula will dispose of pests on Peaches, Plums, or Nectarines. Blister on the last-named is more than ordinarily prevalent.

Standard Pears.—A look round the old standard Pears in the grounds—planted chiefly for their effect when in bloom—shows that the set is very heavy—beating, indeed, that of the finer varieties on the walls. One in particular which shows up well is the old Moor Fowl's Egg, the crop of which will be very heavy. All trees which promise a good return are being mulched in order to give the young fruit a fillip.

Melons and Cucumbers.—The final planting of these has been made on specially prepared hotbeds. The material was not all that could have been desired, but, as there are hot-water pipes in the pits, no misgivings are felt as to the ultimate success. W. McGurrog.

Balmæ Gardens, Kircudbright.

ROYAL HORTICULTURAL SOCIETY.

JUNE 20TH, 1916.

HARDY flowers dominated the fortnightly meeting held on the above-named date. The *Pæonies* from Somerset have probably never been surpassed for fine quality or richness of colouring, the flower being also worthily represented from many other sources. The *Delphinium* was also in considerable force, though this fine border flower had not attained its best. Pinks, too, were charming, and for their fragrance alone are worthy of far more attention. The hybrid *Primulas* from Messrs. Bees attracted everybody, and demonstrated great progress as well. The finest thing among *Roses* was the brilliant *R. Moyesi*. It is a great gain. Neither greenhouse flowers nor *Orchids* were present on a large scale. Several important novelties received recognition.

HARDY FLOWERS.

The most imposing exhibit of these was that of *Pæonies* and *Delphiniums* from Messrs. Kelway and Sons, Langport, Somerset, the whole occupying two entire oppositely-placed tables. The *Pæonies* were much the best, and rarely have these sumptuous June border flowers been more finely displayed. Single-flowered and semi-double flowered varieties were very good, and of these we select *Mafeking* (crimson), *Queen Alexandra* (white, lemon centre)—of this there was an exceptional display—*Columbus*, and *Countess S. Palle* (pink shades). The finest of all, however, was *King of England* (satiny-rose with a mass of scarlet and gold petaloids in the centre). Of *Delphiniums*, *Rev. E. Lascelles* occupies a pedestal of its own, a fine contrast in rich purple and white. Other good ones were *Effective* (sky-blue), *Lovely* (of the same tone with bronzy

tinting), *Dorothy Daniels* (rich blue, white centre), *Opal*, and *Zinfandel* (imperial purple).

Messrs. Bunyard and Co., Maidstone, showed many good *Pæonies*, the finer and more distinct being *La Perle* and *Mme. Roussilon*, both of pink shade and double flowered. Of *Delphiniums*, *Queen Mary* (lovely sky-blue with white centre) and *Rev. E. Lascelles* were the best. *Iris intermedia* was a notable plant here. It is of the *I. ochroleuca* set, not far removed, probably, from *I. ochraurea*, and very handsomely proportioned. It is ivory-white and yellow. The bank of hybrid *Primulas* from

Messrs. Bees, Limited, Liverpool, was something to remember. Hybrids chiefly of *Beesiana* and *Bulleyana*, and possessing the fine vigour and garden value of both parents, they embrace every conceivable shade of orange, orange-scarlet, flame-red of many shades, and not least, delicate lilac tints on the border line of mauve that are quite new among hardy *Primulas*. The beauty of the whole, and their exceptional vigour, appealed strongly to hardy plant lovers.

Mr. G. W. Miller, Clarkson Nurseries, Wisbech, arranged a considerable variety of hardy flowers. Largely of *Delphiniums*, the group contained *Campanulas*, double white *Rockets*, *Heuchera*, *Pæonies*, *Potentillas*, and much besides. *Pæonies* were the chief of a large exhibit from

Messrs. T. S. Ware, Limited, Feltham, many of the best garden and commercial sorts being staged. *Duchess de Nemours* (a magnificent double white), *Alba sulphurea*, *Charles Leveque* (beautiful pink), *W. T. Ware* (soft pink), and *Water Lily* (blush-pink) were some of the best. The single crimson, *P. lobata*, was also on view.

Messrs. Dobbie and Co., Edinburgh, showed a remarkably good lot of *Canterbury Bells*, more particularly of the cup and saucer forms, which doubtless are the more showy and popular. These were in pink, blue of several shades, and pure white, similar colour shades being staged of the single varieties. Obviously a strain of much excellence was represented.

Messrs. R. H. Bath, Limited, Wisbech, filled a double, low-placed table with the choicest *Pæonies*, *Spanish Irises*, and *Delphiniums*. Of the *Pæonies*, *Marshal Oyama* (rose-coloured guard petals and gold and scarlet petaloids) was of outstanding merit. *Solfaterre* (creamy-white), *Philomele* (rose), *Mme. Charles Leveque* (soft pink), *Zarina*, and *Duchess de Nemours* (an indispensable among double whites) were among the best.

Mr. Amos Perry, Enfield, contributed a group in which *Pæonies*, *Irises*, and *Delphiniums* played a part. *Pæonia* *Duchess de Nemours*, *Iris Richard II.* (*Award of Merit*) (a fine contrast of white and purple), *I. Snow Queen* (an indispensable of the *I. orientalis* set), and *I. Caterina* were notable things. Most attractive, too, was a mass of the sky-blue *Delphinium Belladonna* semi-plenum, a lovely plant of 2½ feet high.

Mr. G. Reuthe, Keston, showed many alpine and choice shrubs, chiefly rare *Rhododendrons*, *Ozothamnus rosmarinifolius* (a mass of white blossoms), the brilliant *Erica cinerea pygmaea*, *Olearia dentata vera*, and *Coronilla cappadocica* (yellow) being some among them. An inflorescence of *Gentiana lutea*, 3½ feet high, was also remarked.

Messrs. Barr and Sons, Covent Garden, W.C., staged some good *Irises*, notably *I. ochroleuca Innocence*, the royal purple-coloured *I. chrysographes*, and *I. fulva* being of the number. Of *Spanish Irises*,

Twilight (light blue and buff) is one of the most distinct we have seen. Garden Pinks constituted the chief of an exhibit from

Mr. B. Ladhams, Shirley, Southampton, a considerable collection being staged. Elsie and Nellie are of rose colour, very striking and distinct; Inchmery (pale pink), Mrs. Pryor (white, crimson base), Aurora, and Salmon Queen being others of note. Handsome vases of cut sprays of *Abutilon vitifolium album* and *Carpen-teria californica* were also on view.

ROSES.

Much the most interesting item in this section was the striking group of *Rosa Moyesi* staged by Mr. J. C. Allgrove, Middle Green, Langley, Slough. This remarkable species was found in Western China by Mr. Wilson. Gaining an Award of Merit eight years ago, the higher award of a First-class Certificate was now granted it. Single-flowered, the coppery-crimson colour produces a most brilliant effect in the sunlight, and with golden anthers and elegant leafage the picture is complete.

Messrs. Chaplin Brothers, Waltham Cross, staged the H.T. Rose Mrs. A. W. Atkinson, one of the certificated varieties at this meeting. The colour is a fine ivory-white, the full, handsome flowers lightly perfumed. Old Gold in the bud state was lovely. Lord Kitchener, a new, highly-fragrant red, was very fine. Mrs. C. E. Pearson was also good.

Messrs. W. Paul and Son, Waltham Cross, had a capital exhibit of Paul's Scarlet Climber, also Cordelia (a large white-flowered seedling climber which is full of promise).

Messrs. B. R. Cant and Sons, Colchester, had several good single Roses, Cupid, Irish Glory, and Una, the last named not strictly single flowered. Lady Hillingdon, very rich in colour, was also on view. The new climbing *Wichuraiana Rose*, Nancy Williams, was shown by

Dr. Williams, Harrow-on-the-Hill. It is of rosy-peach colour, flowers large, and said to be a most vigorous grower.

GREENHOUSE PLANTS.

Nothing new was observed among these plants. *Streptocarpus*, of an excellent strain in the cut state, were daintily set up by

Mr. E. Beckett (gardener to Hon. Vicary Gibbs), Aldenham House, Elstree. White, pink, blue, violet, and other shades were observed. A group of growing plants of these and *Gloxinias* was staged by Messrs. John Peed and Sons, West Norwood, S.E., the latter particularly good. Messrs. W. Cutbush and Son had a group of the recently introduced Ivy-leaved *Pelargonium Radiaunce*. It is of a distinct scarlet shade.

Messrs. H. B. May and Sons, Edmonton, filled a table with groups of *Verbenas*, *Hydrangeas*, and an interesting variety of *Ferns*. *Fuchsias*, *Heliotropes*, Ivy-leaved *Pelargoniums*, and *Lantanas*, standard-grown all, were arranged throughout the group. Mr. J. C. Jenner, Rayleigh, Essex, and Messrs. Stuart Low and Co., Enfield, were the only exhibitors of *Carnations*, the latter showing well of *Princess of Wales* (pink), *Nell Gwynne* (white), and the Hon. Charlotte Knollys (scarlet) of the *Malmaison* section.

SIRUBS.

The Donard Nursery Co., Newcastle, Co. Down, showed *Tricuspidaria lanceolata* (*Crinodendron Hookeri*), the same firm showing the *New Zealand Olearia semidentata*, a lovely plant with bluish-lilac florets and purple disc.

Messrs. Paul and Son, Old Nurseries,

Cheshunt, received an Award of Merit for *Deutzia crenata magnifica*, the best of its class, the snow white, semi-double flowers being most effective.

Messrs. J. Cheal and Sons had, among others, bunches of *Abutilon vitifolium*, *Cistus salviifolius corbariensis* (very pure white), and *Philadelphus Bouquet Blanc*.

ORCHIDS.

Messrs. Sander and Sons, St. Albans, received a cultural commendation for a finely-grown example of *Laelio-Cattleya Gottoiana*, var. *Imperator*. L.-C. *Aphrodite albens* and L.-C. *Martini* were also remarked.

Messrs. Flory and Black, Slough, showed a pretty group of *Disas*, D. Blacki, D. B. Langley variety, and D. Luna being the chief. In shades of rosy-scarlet they were very fine. *Miltonias* were a feature in the group from

Messrs. Charlesworth and Co., Haywards Heath, the more conspicuous being M. *Charlesworthii* and M. *vexillaria Lyoth*. There were also good *Cattleyas*, *Odontiodas*, and *Odontoglossums*.

A complete list of the certificated plants and medals awarded will be found in our advertisement columns.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Soil for Cyclamens (*Essex*).—A good potting soil for *Cyclamens* is two-thirds loam, one-third leaf-mould, with a little mortar rubble and silver sand. In winter they should have a temperature of from 50 degs. to 60 degs.

Roses with green centres (*Fred Freeman*).—The green centres in the *Roses* you send are usually caused by a check of some kind, such, for instance, as a spring frost. Where it is possible to detect these malformed blooms it is a good plan to remove them early and so encourage the smaller buds. Another cause may be that the soil is exhausted, in which case a mulch of rotten manure and frequent heavy waterings would do much good. Some *Roses* are liable to suffer in this way more than others, and all such should be discarded.

Scale on Ferns (*One in Difficulty*).—The fronds of *Nephrolepis* you send have been so badly attacked by brown-scale that the best thing you can do is to cut off all the fronds and at once burn them. Encourage the plants to start afresh, and watch closely for any scale on the new fronds. If any appear, lay the plant on its side on a table, then well wash each frond and stem with soapy water, using a soft brush, taking care that the scale is removed. Afterwards syringe well with clear water. This pest can only be kept in check by constant cleansing in the way advised. There is also white-fly on the fronds, but the cutting off of the fronds and burning them will clear this off.

TREES AND SHRUBS.

Cutting down Rhododendrons (*Mrs. F. Otway Johnson*).—As the *Rhododendrons* are so old there is considerable risk if they are cut back into the hard wood of their not breaking out in a satisfactory manner. Without seeing them it is difficult to advise as to how far they should be cut, and we can only say, do not cut them back farther than is necessary to ensure a shapely plant. The first half of the month of April is a very good time to carry this out. When cut back and the spaces between the plants are clear, after having given them a good soaking of water, lightly fork in a liberal top-dressing of leaf-mould or peat, as this will not only afford fresh rooting material for the active surface-roots, but also act as a mulch during dry weather. Young *Rhododendrons* may be planted at any time during mild weather from October to April.

VEGETABLES.

Manuring Asparagus beds (*A Grower*).—Salt is all very well as a manure, but it should be used very sparingly. A light dressing of 3 lb. to the rod is ample if strewn amongst the

stems a little later. If sown on the ground too early it makes the ground cold, and, should frost come late, may do much harm. We prefer an occasional dressing of sulphate of ammonia, given about twice during the season, and even one good dressing of soot. Guano, also, is helpful if well washed in. The great object of these dressings must be to promote strong summer growth, as the stronger this is the finer will be the crowns and stems the following spring. You must leave your beds to perfect all their stems or growths this season, then next spring you may cut some of the earliest heads for about a month. Then in succeeding years you may cut up to the end of June at least. Do not touch the *Asparagus* growths to cut them down until late in the autumn, when they have turned quite brown.

SHORT REPLIES.

Novice.—The best way would be to burn them, unless you are trenching the ground deeply and can bury them in the bottom of each trench as the work goes on.—*Miss J. R. Fraser.*—Your Sweet Peas have been evidently sown far too thickly, while their poor condition also shows that the plants have been dry at the roots. Give the row a good soaking or two of water and apply a mulch of rotten manure.—*R. Owens.*—Let the *Gladioli* remain in the soil until the foliage has ripened off properly, then they may be lifted and hung up to dry. When the foliage has decayed remove it and store the corms until planting time again comes round. Yes; the *Violas* may be propagated at the time you mention, but be careful not to use the flowering shoots. Only those that spring from the base of the plant are of any value as cuttings.

—*F. Otway Johnson.*—The phenomenal *Loganberry* resembles the ordinary *Loganberry*. The common *Loganberry* should succeed in a cool house if given the treatment detailed by Mr. W. Allen in our issue of June 17th, page 293.—*Glemsford.*—The empty chrysalis of green-fly.—*J. C. Rags.*—Are you quite sure that the woodlice are the cause of your *Cucumber* plants failing? From what you say, we are inclined to think that the plants have been attacked by gangrene. If you would kindly send a complete plant, then we could probably help you.—*B. J. D.*—Without seeing your plants, it is very difficult to say what is the cause, but we should, from what you say, imagine that dryness at the roots is the cause. Did you prepare the ground for the plants by deep trenching and mixing some lighter soil with the staple?—*Mrs. Allgate.*—We should say that *Hobday's "Villa Gardening,"* from this office, price 2s. 6d. net, would answer your purpose.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*Thos M. Skinner.*—1, *Erigeron speciosus*; 2, *E. Roylei* probably, specimen not in good condition; 3, *E. Coulteri*; 4, *E. philadelphicus*.—*A. M. L.*—A, *Veronica spicata*; B, *V. Teucrium*, var. *dubia*; C, *V. prostrata*. Only three specimens came to hand.—*R. Fieldhouse.*—*Rosa rugosa* blanc double de Coubert.—*Glemsford.*—*Syringa Emodi.*—*J. Mann, Symington.*—1, *Coronilla Emerus*; 2, *Spiraea flagelliformis*.—*Fernside.*—1, *Saxifraga umbrosa serratifolia*; 2, *Lychnis Viscaria flore-pleno*; 3, *Helianthemum coccineum flore-pleno*; 4, *Helianthemum vulgare album*.—*S.*—Please send better specimens, as all the blooms had fallen.

The National Rose Society.—The great summer show of the National Rose Society is to be held in the Royal Botanic Gardens, Regent's Park, on Friday, June 30th, and the takings at the gate on that occasion will go to the funds of the British Red Cross Society. A large attendance is anticipated, and the Society hopes that a very substantial sum will be secured for this excellent object which appeals to all at the present time.

THE WILD GARDEN AT MIDSUMMER.

It is forty years since Colonel Baskerville, then a young officer, began a modest trial of a wild garden. Now, after forty years, I have had the pleasure of seeing the result. As at close upon the longest day the early spring flowers had all passed away—Crocus, Grape Hyacinth, Daffodil, and many welcome spring flowers—and with them the great flush of spring beauty, I saw the summer flowers only. Best of these was the beautiful display of the old Lupins so common in borders. For many years one has known this plant in mixed borders, but its flowering season was so short that it became a nuisance there, whereas scattered in the wild garden in large groups under trees the beauty of it is extraordinary. There is much variety in the flowers, the bi-coloured forms and different shades. The plant could not have looked better in its native home. The effect of these plants as seen between and under the trees was heightened.

In the same way the Oriental Poppies were at their best. These plants are so strong in growth that they take up much room in mixed borders and when their short bloom is over are in the way there, but in woodland their effect is splendid; when they pass out of bloom they are not missed among the other vegetation.

The ground occupied by this wild garden was not the result of any set or paper design, simply of making use of some woody places. In many country seats where the woodland comes near the house we often see Brambles and other weeds forming an undergrowth, when, by making a wild garden, we might get a fine growth of handsome plants and at the same time effects not to be got with the ordinary border or garden. No design is needed, it is merely a case of taking advantage of a likely place. Easy turf walks run through the wild garden, and plants of climbing habit like single Roses and Clematis have their full sway. In these days, when labour can hardly be spared for the garden, this aspect of gardening deserves attention. There is little labour required besides the first planting. This year tall Grasses and weeds have had their own way, and, to my mind, the beauty is all the greater for it.

W. R.

NOTES OF THE WEEK.

A giant Poppy.—A giant *Papaver nudicaule* is flowering here. The stems are just over 3 feet 3 inches in height, and the flowers over 3 inches across.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed*.

A graceful yellow Honeysuckle (*Lonicera villosa*).—The best yellow Honeysuckle I have seen, pretty soft yellow buds and blooms, with soft velvety leaves. A free grower on pergola at Friar Park.—W.

Blue flowers.—You write about blue flowers. I rejoice every year in the wonderful liquid blue of *Phacelia*, which does very well here. Sometimes we have had a second bloom in the autumn from self-sown plants. Our great *Wistaria* has flowered splendidly, and in spite of the inclement weather many things in the spring garden have done remarkably well.—A. F. KIRKPATRICK, *The Deanery, Ely*.

The war and the garden.—Labour, especially in some districts where vast munition works are in progress, is practically unobtainable, and many things are being perforce left undone in the garden. It is strange in large gardens to see beds and borders which for long years have been brilliant with summer flowers now devoted to Potatoes and other vegetables to serve a double purpose—food production and labour economy.—S. M. D.

Habranthus pratensis in the west of Scotland.—*Habranthus pratensis* has been grown for years in one of the borders in the garden of the Marquis of Ailsa at Culzean Castle, Ayrshire, where it is hardy and flowers annually. The flowers are bright and effective in their season, and quite as brilliant as any grown in the south. It has not yet been extensively tried in the south of Scotland, but evidently prefers—indeed requires—specially favoured gardens.—S. ARNOTT.

Clantheus puniceus in Sussex.—This climber has (until heavy thunder showers damaged the blossoms) been a mass of bloom on the south wall of this house. It has passed through two winters protected only by a mulching of stable manure over the roots. The border is very dry. I note your correspondent Mr. H. H. Worthington mentions his plant as being in "sandy soil." Probably the failures in Sussex have been caused by the cold, damp nature of the subsoil in so many parts of the county.—M. W., *Fir Tree End, Haywards Heath*.

Geranium anemonæfolium Lowei.—A vigorous, tall *Geranium*; rosy-purple flower; a good rock and border plant. In the same garden I saw a little *Geranium* named *Traversi*, a distinct kind with leaves like those of a little Mallow. Very dwarf plant with pretty rosy flowers. Rock garden, Friar Park.—W.

Pentstemon heterophyllus.—This, with its Gentian-like hue, is the most attractive of those American plants which we have. The plant varies a little from seed, and the finest form we have seen is in the rock garden at Friar Park, a large colony well set in rocks, as it might be in its native mountains. The plant is so distinct as well as beautiful that it deserves to get a good place in the flower garden. Where of doubtful hardiness it should be raised every year.

The Spanish Furze (*Genista hispanica*).—Set well up among other dwarf shrubs on the elevated parts of the rock garden, this, when one is a little away, looks like a ball of gold. Only once, in a winter of almost arctic severity, a number of years ago, has it been much injured by frost. Then it was cut to the ground, but sprung again from the base, and in a year or two was as fine as ever. The flowering shoots are unarmed, but lower down, the branches are covered thickly with sharp spines. So freely covered is the bush with bloom that in many years no green is visible on the top of the plant. In gardening books its height is given as 1 foot, but under favourable conditions it grows higher. *G. hispanica* may be kept in bounds by cutting it hard back after the flowering is over.—S. A.

Habranthus pratensis.—I was pleased to see Mr. Allan's note about this fine *Amaryllid*, which is not admitted to the "Kew Hand List" of 1902. I believe it is now classed in the genus *Hippeastrum*. Like so many Chilean herbs and shrubs, it agrees well with the climate of the west coast. One should plant it thoughtfully as regards its neighbours, for the vermilion blossoms are of so vehement a tone as to accord ill with most other flowers. When it first came here I happened to plant the bulbs next to an Austrian Copper Briar, whereof the rich hue was made to appear dingy alongside of the newcomer. But I have now hit upon a perfect companion for the *Habranthus* in the shape of *Pan-cratiium illyricum*, which, flowering simultaneously, and with an equal relish for a sunny exposure, affords a grateful contrast with its snowy bloom to the volcanic

flames of the other. A few seeds of *Nemophila insignis* scattered round the place provide a suitable carpet. — HERBERT MAXWELL, *Monreith*.

The Bladder Pod (*Vesicaria utriculata*) is flowering well this season from plants now in their second blooming season, while many self-sown seedlings show how readily it comes from seeds. The yellow flowers, borne on rather arching heads, last for a long time. Plants after a few years become bare towards the base, so that it is as well to replace them with younger stuff. Cuttings may be struck or old plants cut back after flowering, but seedlings are more vigorous and are really best. — S. ARNOTT.

Antirrhinum Asarina.—I saw three distinct plants under this name, all with large flowers of the Snapdragon form, each beautiful; two kinds with narrow leaves and one with roundish, heart-shaped leaves. Falling over rocks, each gives a good effect, and they deserve the attention of a man with a botanical turn of mind, who would determine the names of the three which seem to me to be distinct. All three were seedlings from the same plant. At Friar Park (mid-June). — W.

The weather in June.—June weather has been the most severe experienced in the Sheffield district for thirty-one years. Six degrees of frost were registered at High Green on Saturday, the 17th, and the lakes were frozen over with ice half an inch thick. In the agricultural areas scores of acres of early Potatoes were cut down by the frost, and farmers have no option but to plough them up and replant the ground with vegetables. Enormous damage has been done. A violent north-easterly wind and spells of frost in the Lothians during the last few days have caused enormous damage to fruit gardens and vegetation as a whole. Crops which at one time promised well have been seriously affected.

Tree Lupins.—In the north of England Tree Lupins do not seem to do well, but they revel in the soil of this district. They do not mind however dry they get, and grow very quickly into large bushes, which are, at the time of writing (June 14th), covered with bloom. Down here the soil is warm and sandy; indeed, an outlier of so-called "green-sand" caps the clay on this hill, and as the outlier is as much as 40 feet thick, water drains away very quickly, making some of the beds extremely dry. Tree Lupins stand the winter here, but in Sheffield they invariably die. I have tried them many times, but they have always perished. In this district they have to be pruned after flowering to keep them tidy, otherwise they get out of hand. They can also be raised from seed sown now. In height they vary. Catalogues say "2½ feet to 3 feet," but this must surely be a mistake, for established plants get up to 5 feet or even more. — E. T. ELLIS, *Brumcombe, Foxcombe Hill, Nr. Oxford*.

Rosa sericea pteracantha.—In the article on "Roses for winter effect," which appeared in the issue of GARDENING ILLUSTRATED for June 17th, no mention is made of this very distinct Rose. The main feature is the enormous spines with which the stems are armed. When young they are of a rich red, translucent character, which gives to a bush of this Rose a very striking appearance. The second year these spines become grey and woody. The typical species is native of a large tract of country in northern India, Burma, and China. In a state of Nature it shows a certain amount of variability in the

flowers, which are white, and each nearly a couple of inches across. In direct contrast to *R. sericea pteracantha* there is a form (denudata) totally devoid of spines. First raised by M. de Vilmorin, at Les Barres, France, *R. s. pteracantha* aroused a great deal of attention when shown at a meeting of the Royal Horticultural Society on September 26th, 1905. A first-class certificate was then awarded it. The spines form such a notable feature in winter, as well as in summer, that it is well worthy of mention among Roses for winter effect. It is now generally distributed, and can be obtained from most dealers in Roses. — K. R. W.

Cooks and Food.—The French have a saying about cookery which has often amused me. I asked Mons. F. Morel, of Lyons, what was the source of it, and he has replied as follows:—"Le cuisinier a fait beaucoup de mal à la cuisine" est simplement une phrase populaire pour dire que les professionnels maladroits nuisent souvent à leur profession. Combien de jardiniers, et surtout ceux qu'on appelle *paysagistes*, tuent le paysage qui leur est confié aussi irrémédiablement que certains médecins tuent leurs malades!

Notes from Berkshire.—Despite the recent inclement weather plants here are nearly a month more forward than those in our Sheffield gardens. The borders are gay with *Anchusas*, *Aquilegias*, *Campanulas*, *Corydalis*, *Erigerons*, *Geranium argenteum*, *Geums*, *Heucheras*, *Iris*, *Lupins*, *Lychnis*, *Nepeta*, *Pæonies*, *Pulmonaria*, *Pyrethrums*, *Trollius*, etc., many of which were only just starting to bloom when I left Sheffield a short time ago. In this district *Polemoniums*, *Doronicums*, and several other early-flowering plants are practically over, but in our Sheffield garden these do not come to their best till about now. In several gardens round about here there are fine mixed borders now gay with *Calendula*, *Pinks*, *Pansies*, *Honesty*, *Marguerites*, *Canterbury Bells*, *Sweet Williams*, early *Pentstemons*, *Oenothera*, *Clarkias*, *Godetias*, *Poppies*, etc. In the rock gardens there are *Armerias*, *Aubrietias*, *Alyssum argenteum*, *Asters*, *Campanulas*, *Erigerons*, *Phloxes*, *Pinks*, and *Primulas*; also *Gentians*, *Hellianthemums*, *Saxifragas*, *Saponarias*, *Sedums*, *Veronicas* in variety, etc. — E. T. ELLIS, *Brumcombe, Foxcombe Hill, Nr. Oxford*.

Saxifraga Elizabethæ.—Of this free-growing, free-flowering sort "Ess," at page 299, writes: "I find there are two distinct plants bearing this name." Your correspondent might almost multiply the "two" by three, since this year Messrs. Waterer, Sons, and Crisp have shown five varieties, each good in its way and quite distinct enough for garden purposes. The greater value, however, of this unusually long procession of varieties of *S. Elizabethæ* lies in the fact that they so succeed each other in their flowering as to afford an almost unbroken chain for several weeks, No. 5 being the latest of the set. This has flowers of a more orange-yellow tone than the rest, and was exhibited by the firm named in splendid condition before the Royal Horticultural Society in mid-April, a specimen I secured lasting to the end of the month quite well, a very late date in the south for any of the set. Other good attributes of No. 5—it and three others have not as yet, I believe, received distinctive names—are its sturdy stems and spreading flower-clusters, both inherited, doubtless, from *S. sancta*, one of the parents of *Elizabethæ*, one of whose varieties it should be noted has been erroneously distributed as *Cherry-trees*. — E. H. JENKINS.

FRUIT.

PLUMS IN COTTAGE GARDENS.

THE spells of frost we had earlier in the year came, so far as this neighbourhood was concerned, before the expansion of the Plum bloom and after it was set, and so there is every sign of a good crop. This, in the majority of seasons, would be both useful and lucrative, but at the present price of sugar there is hardly likely to be much jam-making or opportunity for disposing of the surplus supplies. The receptacles, too, that might be used for bottling, in the way of jars and bottles, have all largely increased in price, especially the glass bottles, and so unless on hand they would mean an additional outlay where a fair quantity of fruit was to be dealt with. Few cottagers, however, seem at present to have gone in for bottling, despite oft-repeated advice in different journals, and the fact that it is a very economical way of securing a supply of wholesome fruit between the last Apples and the advent of Rhubarb. It is interesting to note in some seasons the effect of what might be termed unconsidered protection towards securing a crop. Many of the cottages have a Plum tree on a portion of the wall, and the enormous eaves projecting from the thatched roof keep off several degrees of frost. They have their drawbacks, however, later in the season, for they also keep off the rain, and trees suffer here more than in the open from the attacks of aphid and red-spider unless precautionary measures are taken. They are, unfortunately, often allowed to get into such a bad state, especially so far as red-spider is concerned, that the foliage is ruined for the season. Some growers, however, realise the necessity for anticipating such attacks, and the contents of the wash-tub are saved for a weekly application. *Victoria* and the old *Green Gage* are the two favourite varieties, and a sort that appears to be *Cox's Emperor* is also rather largely grown. — E. B. S.

Hardwick.

Strawberry runners.—If specially good runners are wanted for autumn planting or for forcing, a very good way to secure these is to suppress the blooms of a few lines of the desired varieties and permit the earliest runners to develop the embryo plants upon them. Such plants will not only be early, but very vigorous, and may be relied upon to give a good account of themselves in the season after planting. It is too often the case that Strawberry runners are selected in a haphazard way from plants which have carried a more or less heavy crop of fruit; and it stands to reason that such plants will be weak and quite unfitted to withstand the vicissitudes of our capricious winters. — KIRK.

Fruit-trees in pots.—Stimulants may now be freely given to trees in a cool-house, and syringing is practised twice a day. Formerly, syringing was done in the afternoon round about four o'clock; but the alteration of the time means that this must now be delayed until the watch indicates 5 p.m. For a few days the habit was difficult to overcome. The same tendency had to be guarded against in the case of the closing of the stove and of Melon pits.

The Wonderberry (*Leon Fonteneau*).—The Wonderberry as grown in this country cannot be distinguished from certain forms of *Solanum nigrum* (Linn.), a cosmopolitan weed whose fruits are said to be edible in some countries and poisonous in others (including Britain).

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

TREES AND SHRUBS.

RHODODENDRON DECORUM.

ALTHOUGH *Rhododendron decorum* flowered in this country upwards of fifteen years ago, it is only of late that it has been grown much, for plants were few in number until seed was sent from China by Mr. E. H. Wilson. It had, however, a very near relative amongst the older species, for it has much in common with the fragrant-flowered *R. Fortunei*. *R. decorum* is a native of Yunnan, and is distinguished from *R. Fortunei* by its more vigorous habit, stronger branches, with fewer branchlets, glaucous-green or

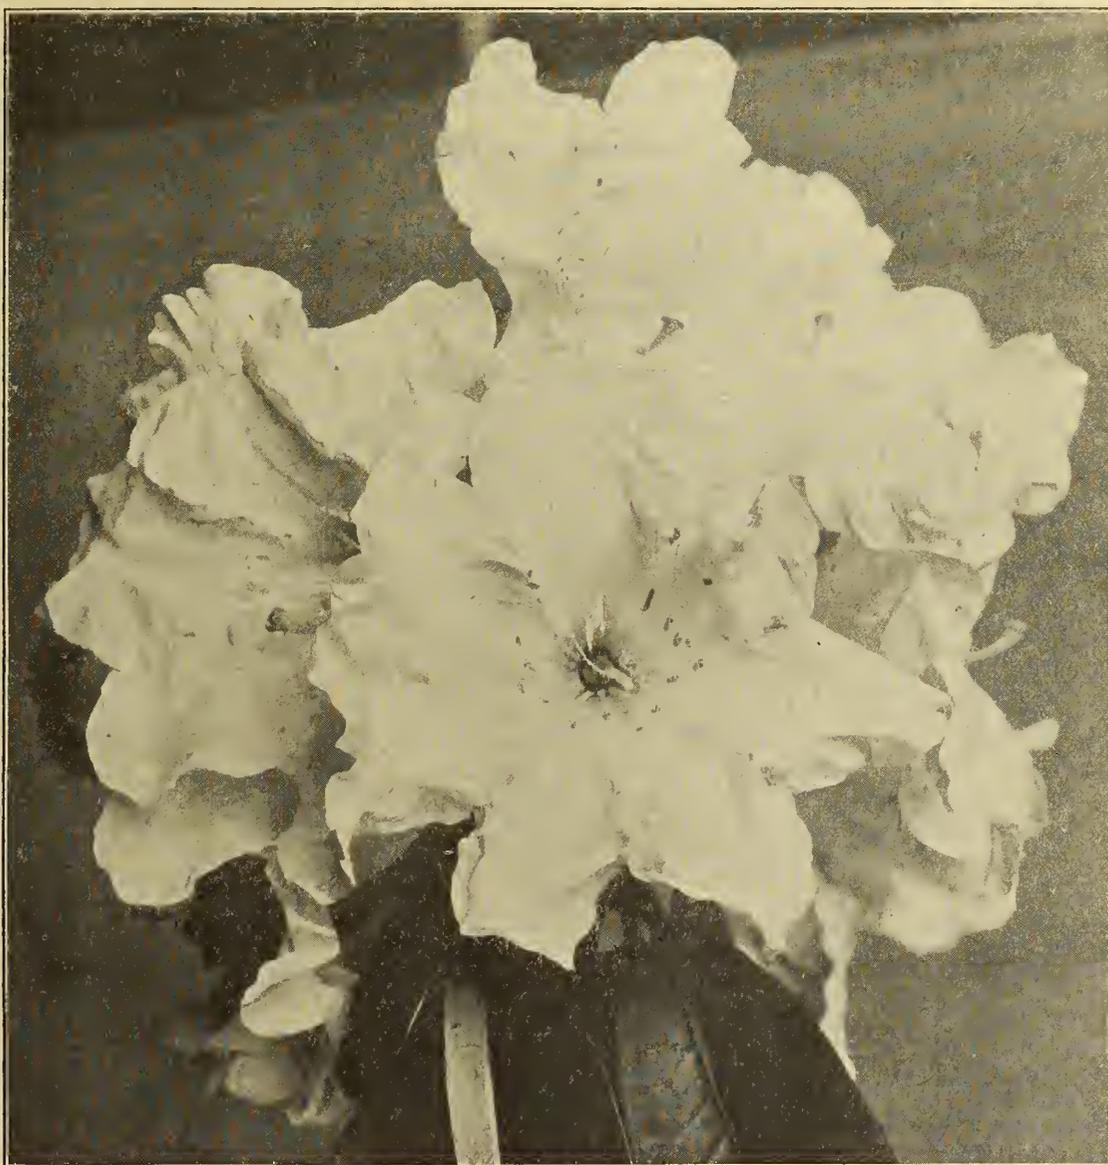

other parts of the same plant less than half that size. The heads of flowers are large and shapely, and suggest that it would make a useful form for crossing with various *R. catawbiense* varieties or hybrids. D.

NOTES AND REPLIES.

Increasing Lilacs.—A neighbour has a splendid double white Lilac-tree. He offers me twigs to root as cuttings. Would they strike at this season of the year in a cool, shady position? What would be the best time for putting them into the ground?—RIDUNA.

[Lilacs do not root readily from cuttings out of doors; in fact, they are more generally increased by layering. Your greatest

Chelsea Show one was previously honoured. They were all shown by Messrs. Waterer, Sons, and Crisp, Bagshot. The variety shown at Chelsea was Bagshot Ruby, an exceedingly free-flowering form with large, rich, crimson-red blooms dotted in the upper part with black. It was shown at the international exhibition by Messrs. Waterer, but did not then receive any award. The varieties selected for awards on June 6th were Donald Waterer, pinkish-white with a deeper-coloured border. The upper segment is dotted with brownish-yellow. Duchess of Teck has a fine cluster of pale rose flowers edged with a deeper tint. In Diphole Pink the blossoms are of a clear

A flowering shoot of Rhododendron decorum.

grey-green young shoots and leaves, and rather later blooming. The flowers are white tinged with pink, each one being about 3 inches across. The leaves are usually larger than those of *R. Fortunei*, those of specially vigorous shoots being 8 inches or more long. The flowering time is late May and early June. Another closely related species is found in *R. discolor*, whose flowers, each 3½ inches to 4½ inches across, white suffused with rose, and slightly fragrant, open about the middle of June. The leaves vary a good deal in size, for while those of specially strong shoots may be 10 inches long and 4 inches wide, there may be leaves on

chance of success will be to take cuttings of the mature shoots during the latter part of August and insert them firmly in a cool, shady spot, mixing some sand freely with the soil. They must then be covered with a hand-light or frame, which should be left on till they are rooted. This will be seen by young shoots being pushed out freely the following season.]

New Rhododendrons.—In 1914 no less than two first-class certificates and five Awards of Merit were given to Rhododendrons, and not one gained recognition in 1915. During the present year three received awards on June 6th, while at the

rose-pink of a distinct and pleasing shade, with yellowish dots on the upper petal. All are of good habit.—W. T.

Dyers' Greenweed (*Genista tinctoria*).—In many parts of the country this showy Broom is found wild, usually as a prostrate or semi-prostrate plant, but sometimes from 6 inches to 1½ feet in height, its rich golden blossoms for the greater part of summer brightening up many a common and hillside, where it often grows amongst short Grass, giving the flowers the appearance of being borne by the Grass. It is distinguished by its small, dark-green, simple leaves, and by its flowers being borne from the points of the

current season's growth. The flowers are in good-sized panicles, which, in the variety elatior, sometimes exceed 1 foot in length. That variety, by the way, is of vigorous habit, growing 2 feet or 3 feet high, and it is improved by an annual pruning in spring, the shoots of the previous year being cut back to within 1 inch or 2 inches of the base. It is not, however, a very long-lived plant, and should be renewed from seed every few years. Of several other varieties, *G. t. flore pleno*, with double flowers, is one of the best for garden planting. Growing a few inches high, it forms a dense carpet and blooms with great freedom. It is increased by cuttings. One defect attaches to this variety, however, for it is often attacked by aphides, which, if not destroyed at once, soon detract from its beauty. The type is an excellent plant for dry, sandy, or stony soil. In such a place seeds may be sown broadcast and the young plants allowed to develop naturally.—D.

Azalea roseiflora.—It is too frequently imagined that this is not hardy, but tests by various people in different parts of the country have proved the contrary. I have grown it in the rock garden for twenty years or more, and it has never suffered in the least.—S. ARNOTT.

PLANTS AND FLOWERS.

CHRYSANTHEMUMS.

CHRYSANTHEMUM NOTES.

SOME time during June the plants should be placed in the pots in which they are to flower. I am rather in favour of a simple compost; at any rate I have seen many mistakes made with various mixtures. Good loam—rotted turf—is the principal item, and if this be naturally light and sandy the addition of bone-meal at the rate of a couple of pounds to a bushel will answer its purpose well. If the loam be heavy then mortar rubble and rotted manure will be helpful. In this case rather more than two-thirds of the whole may be loam, and the bone-meal is added here too. Chop the soil or pull it to pieces with the hands, so that no fibre is wasted. It is not advisable to get it very fine, because the rougher portion can be used in the bottom of the pots over the drainage. Broken pieces of flower-pot should be placed with care over the drainage holes, and the soil rammed down tightly with a blunt stick before putting in the plant. Pots 9 inches in diameter are the more useful generally, although some growers use a size larger for the stronger-growing kinds, and a size even smaller than that first named may be employed with advantage by amateur cultivators who may not desire exhibition blooms. Err on the side of small pots, and ram the soil firmly is not bad advice.

When repotting at this time of the year an item, simple, but of much importance, is to thoroughly soak with water the plants that are to be shifted. This not only helps the ball of earth to come from its old pot without damage to the roots, but it prevents later the old ball becoming dry whilst the fresh soil is wet, thus deceiving the grower and perhaps throwing the plant out of health. For a few days after potting sprinkle the leaves twice daily, but do not do this at mid-day, when the sun is powerful. If these little things be attended to the plants will hardly feel the disturbance, and they can be placed in summer quarters. I like an open spot on a firm ash bottom, and also plenty of room between each plant. It is convenient to stand the plants in rows because later on it will be necessary to

provide wire supports to keep the wind from toppling them over. Of course, each will be provided with a stick, and to this stick the growths should be loosely tied as they lengthen. Bamboo-canes are neat as well as strong. The training should be done in accordance with the wishes of the grower. If a few large flowers to each plant are desired then reduce the stems to three, and so on up to a bushy plant that shall carry a dozen or more. But do not interfere with the upward direction of the shoots, nor is it necessary to "pinch" them to obtain a number. The Chrysanthemum is naturally branching. Routine work in summer is exacting—that is to say we cannot neglect the plants for a single day, unless, indeed, the weather helps us in the matter of moisture. We should look through our plants at least twice a day, and water them only when water is needed. To help in this, tap the pots, and if they give a ringing, hollow sound it is pretty certain that moisture at the roots is required. I always like the soil of my plants in pots to be on the dry side rather than on the wet side at nightfall. The roots are thus kept sweeter when there is moisture in the air to help the leaves. Some gardeners are never satisfied unless they are pouring water into their pot plants—especially Chrysanthemums. It is doubtful, however, if such can be termed successful growers. Nor do I think it good practice to be continually syringing the leaves. It may be beneficial during a spell of very hot weather. In dull times this does more harm than good, inasmuch as it causes mildew. Damping the leaves, if done, should be in the morning and early evening, when the sun has either not gained or lost its full power. For a month or six weeks after potting anything in the way of stimulants will not be desirable.

Disease and pests may include mildew and green-fly. A dusting on the undersides of the leaves with flowers of sulphur in the case of mildew, and either dusting with Tobacco powder or syringing with some insecticide when the latter appears, should be useful remedies. H. S.

NOTES AND REPLIES.

Hardy Chrysanthemums.—A good trio of hardy Chrysanthemums may be found in *Mme. Desgranges* and its two sports, *George Wermig* and *Nellie Blake*. *Mme. Desgranges* is pure white, while *George Wermig* is of a good shade of yellow. *Nellie Blake* is equally good in its colour—a dark red; and as these three varieties are identical in habit and flower simultaneously, their value is obvious. Here, naturally, they bloom later than further south, but they are more appreciated for that very reason. After the ordinary run of hardy Chrysanthemums is over, the display is prolonged by the use of these varieties. It is sometimes necessary to protect them, in the event of early frosts, by tiffany or scrim over the blooms, but it is well worth going to this trouble, as the interval before the earlier greenhouse Chrysanthemums become available is bridged over.—W. McG.

Pompon Chrysanthemums.—The notes of your contributor "E. G.," re "Early or semi-early Pompon Chrysanthemums," in the issue of December 11th, page 742, are very interesting, and may reasonably be expected to create a desire to possess some or all of the varieties he mentions. But it is not easy to get on the track of these varieties. It appears that very few of the advertising Chrysanthemum specialists grow Pompons, and the list of a firm which does grow them contains among the score or so of varieties there named not one of "E. G.'s" varieties.—F. J. B., *Barnet*.

A late white Chrysanthemum.—Market growers on the look out for a white to produce high quality flowers late in the year should try *Enfield White*. It is excellent, and invariably commands high prices. It is a capital grower and a very free bloomer. Probably we shall see a great deal of it during the next few seasons.—S.

INDOOR PLANTS.

PHYLLOCACTI.

To one whose horticultural memory extends back for twenty years or more the neglect into which these showy-flowered Cacti has now fallen is very noticeable. After having been generally grown for many years they were taken in hand by Messrs. Veitch, who raised a great number of charming varieties. Some idea of these may be formed by the fact that during the years from 1893 to 1899 no less than seventeen varieties of Messrs. Veitch's raising received Awards of Merit from the Royal Horticultural Society. For several seasons, too, a group of these Cacti formed a very noticeable feature of Messrs. Veitch's group at the Temple Show. Among them were flowers of widely different tints, from pure white or nearly so through various shades of pink to deep scarlet. Some of the subtle shades of violet, purple, and orange, which in their metallic lustre appeared to be of different tints when viewed from different standpoints, were very interesting and attractive. Within the years named these Phyllocacti enjoyed a period of popularity, but they soon began to decline in favour, and they are now very little cultivated. This is a pity, as they can be well grown by the amateur with but a single greenhouse, as well as in more pretentious establishments, and they are extremely showy when in bloom. Probably their decline in favour is due to the fact that the individual blossoms do not last long, and they are not at all adapted for cutting, which is the standard by which most flowers are judged nowadays. As a set off, however, they are of easy culture, give but little trouble, and, treated reasonably, can be depended upon to give a good display of blossoms. They are very easily propagated by cuttings of the branches taken off at a joint to a length of 4 inches to 5 inches and put into small pots of sandy soil. The cuttings do not need to be shaded; indeed, except during the flowering period the plants should be fully exposed to the sun. Repotting, if needed, should be done as soon as possible after the flowers are over, a most suitable compost being made up principally of loam, lightened according to its consistency with a little sand, broken brick rubble, and leaf-mould. Effective drainage is, of course, necessary. The plants may be freely watered during the summer, lessening the supply as autumn advances, while in winter they must be kept moderately dry, but not parched up. A thorough ripening by exposure to full sun in autumn is very essential to the formation of flower-buds. W. T.

NOTES AND REPLIES.

Zonal Pelargoniums to flower in June.—Would you please be kind enough to inform me when is the best time to take Pelargonium cuttings so that I may have them in bloom about the third week in June, and what is the best compost to use for potting.—LANCASHIRE LAD.

[You should lose no time in taking the cuttings of Pelargoniums which you require to form good flowering plants by the third week of next June. It is, in the first place, essential that good, sturdy shoots are selected for the purpose, as weak and attenuated ones, though they root readily enough, will never lay the foundation of good plants. If your cuttings are put into pots or boxes these must be effectually drained. A suitable compost for the cuttings may be made up of two parts loam to one part of leaf-

mould and nearly one part of sand. It should be pressed down moderately firm. The cuttings may at this season be stood out of doors. As soon as they are well rooted they must be potted singly into pots 3½ inches to 4 inches in diameter, using much the same compost as that for cuttings. Directly the roots take possession of the new soil the tops of the plants should be pinched out in order to induce a sturdy-branching habit. A second or even a third pinching may, in the case of some, be necessary later on. During the winter the plants should have all the light and air possible in order to prevent them becoming drawn. For the spring potting the soil should be of a more holding nature, and consist mainly of good loam with a sprinkling of sand, bone-meal, and well-decayed manure. If there is any doubt about insects in this last it should be sterilised or omitted altogether. Should the loam be of a very heavy nature a little leaf-mould will be beneficial.]

Imantophyllum miniatum.—For the decoration of greenhouses, conservatories, or windows this is one of the finest plants

they may be able to ramify the more freely. To winter the *Imantophyllum* well and safely, a higher temperature than that of an ordinary greenhouse is required, but where this cannot be afforded it should have the warm end, and be kept a little drier than usual. In order to get plants to flower freely, the point is to treat them well through the spring and summer by supplying them liberally with water and liquid manure, as then they are sure to make strong growth.

Camellias on walls.—For covering the back walls of conservatories or plant houses nothing is equal to Camellias, for the partial shade that is so detrimental to many other plants seems to quite suit the Camellia. We have seen a back wall of a conservatory covered with Camellias, and a lovely background they make; for even when not in bloom their deep green foliage is always pleasant to look at. The single and semi-double varieties are equally, if not more, effective than the very double sorts, and the colouring is so brilliant that I believe they will be rather more popular than hitherto. For covering walls a good

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

WAHLENBERGIA.

(SYN. *EDRAIANTHUS*.)

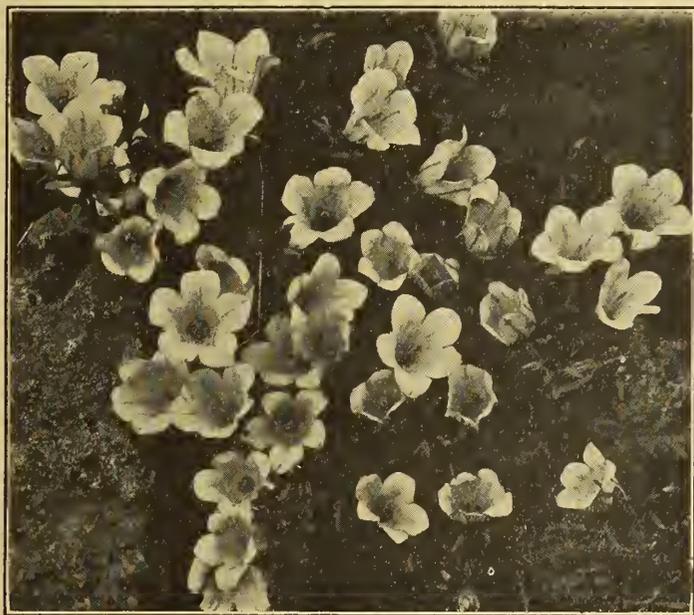

In nurseries and in catalogues of hardy plants this pretty genus of the Bell-flower order is usually found under the synonym given above. Essentially rock-loving, some special provision is necessary if we would realise, so far as this is possible in lowland gardens in England, a little of the wealth of beauty and colouring afforded by the best kinds when rightly placed and well grown. These *Wahlenbergias* dislike much soil about them, indeed, it is not too much to say that, apart from such a pest as the slug, soil and soil damp are among the chief drawbacks to their successful cultivation when the ordinary methods of growing them are indulged in. Failures may be turned into successes, however, by planting in rocky crevice or fissure, or in those instances where the rock garden is not of an extent to admit of such being done, the rougher surfaces of rock walls may be turned to good account by sowing seeds or planting seedlings freely in suitable positions. One of my earliest successes was the outcome of introducing seedlings into a rudely-constructed wall. The idea was quite successful, and, moreover, on the rock wall these choice plants rarely suffered from the attacks of slugs. If, however, it is desired to create a colony of any one of the species on a sloping rock bank, the best plan will be to excavate the soil to certainly one-half, replacing the portion removed by small stones, old mortar, or limestone chippings. In this way, and with the plants fairly dry at the ground level, there is every hope for success, more so where a soil very light and sandy, and with a little peat mixed, is prepared for their reception. Firm planting about the collar of the plant and an elevated position should not be overlooked by the planter.

All the species are low-growing, not more than 4 inches or so in height, and, composed of a chief central rosette of leaves, send forth their trailing or procumbent flower-stems in many directions. Seeds form the best means of increase, some care being necessary to prevent damping in the early stages, plenty of grit and crushed limestone being as important as soil to these plants. Manure should on no account be employed. The following are the best kinds:—

WAHLENBERGIA DALMATICA.—Blossoms of a rich purple or violet, in clusters not unlike a Campanula, each cluster containing from six to a dozen flower-stems. This is one of the easiest to cultivate, and at the same time one of the most vigorous of the genus. By reason of the nearly prostrate habit of growth the plants in grouping should be kept well apart. Native of Dalmatia and flowering in June.

W. PUMILIO.—A small-growing and compact habited plant. The solitary blossoms are erect and of a purplish-blue tone, which is variable in seedling plants. A characteristic of the species is the covering of minute hairs on the upper surfaces of the leaves, giving it, when in a rather dry position, a silvered appearance. May and June.

W. SERPYLLIFOLIA.—This, here figured, to my mind is the most beautiful of the genus, producing handsome, erect bells of a royal purple colour on trailing wiry stems. I know of no alpine that is calculated to give greater satisfaction, than this when well grown. Flowering period May to June.

Wahlenbergia serpyllifolia in the gardens at Lilford Hall, Oundle, Northants.

that can be grown, as it sends up numerous heads of orange-scarlet Lily-like flowers that last a long time in perfection. In habit and general appearance it greatly resembles the *Agapanthus*, but has stiffer and darker foliage, and blooms resembling those of the *Vallota purpurea* in size and colour, so that anyone acquainted with the latter may easily imagine what a fine effect they produce. The *Imantophyllum* makes a fine window plant, as it stands the treatment well, and, being fond of water after it gets in a pot-bound state, it is never injured by standing in a pan or being kept wet. Dust is the great enemy to most window plants, but as the *Imantophyllum* has thick, shining, leathery leaves there is no difficulty whatever in keeping them clean, as they may be easily washed without injury. In order to increase this plant take off any suckers which it shows, if possible with roots attached to them, as then they are sure to grow if placed in a pit or house where they can have a little heat for a time. The soil that suits them best is fibrous loam and sand, but as the roots are very large and fleshy, the loam should be rough and lumpy and the potting loose, in order that

border of at least 5 feet or 6 feet in width should be made of good fibrous turf, peat, and sand, and enriched by means of top-dressings of cow or sheep manure, and the plants should not be stiffly trained to the wall, but allowed to spread out in large masses. We surface-dress the border every year with the richest manure we can get, and the plants are always loaded with blossoms, the foliage very deep green; and although the double whites, pinks, and crimsons are extremely handsome, the semi-double sorts are, as I have said, quite as effective from a decorative point of view.—T.

Arum Lilies.—In the course of the week *Arum Lilies* have been planted out. Diversity of opinion exists—and will always exist—as to the relative value of drying off and planting out these Lilies. Good results can be attained either way, and circumstances must decide which practice it is better to follow. In planting out, I always use a place fully exposed to the sun, and of rather a poor nature. There the foliage speedily ripens off, and the crowns are to all appearance, and certainly judging by results, equal to those which have been sun-baked in their pots during summer and autumn.—K.

GARDEN FOOD.

SPOILING GOOD VEGETABLES.

WE see in the *Queen* an article by Mrs. Peel on preserving vegetables mostly by using quantities of salt. Physiologists of the day tell us of the bad effects of using much salt, and vegetables so treated may be anything but wholesome. In the case of Cucumbers the markets are now well supplied through the year, so what can be the object of preserving them? We give two of the recipes here, merely remarking that it is a way of spoiling good food.

PRESERVED CUCUMBER.—Choose small and young Cucumbers, put them into jars, pour a brine over them, and cover down. When wanted, remove the rind, and use them in the same way as fresh Cucumbers. For the brine: Take 2 pints of water to 1 pint of vinegar and 1 lb. of salt, put it all into a pan over the fire till the salt is melted, let it stand to settle, then pour it off clear before using.

TOMATO CATSUP.—Take half a peck of sound, ripe Tomatoes and wipe them well, quarter them, place on dishes, and scatter over them $\frac{1}{2}$ lb. of salt. Leave for twenty-four hours, drain the juice through a clean tammy or hair sieve into a pan. Add two dozen small Capsicums and ten Shallots, or, if not to hand, 2 oz. of whole Pepper and four tablespoonfuls of Onion juice. Simmer for half an hour and then add the Tomato which has been pulped through a fine hair sieve. Cook for thirty minutes more. Bottle, cork, and seal.

UNLEAVENED BREAD.

I HAVE now the pleasure of eating bread that is really natural and good. I get the flour from the Artox Mills, Rotherham, and the bread is made by my cook. We shall never have a good bread until yeast is got rid of altogether. The following is the recipe:—

Put 1 lb. of wholemeal into a basin, with a pinch of salt, if liked. Work well into the wholemeal a piece of butter the size of a Walnut. Then gradually stir in a $\frac{1}{2}$ pint of cold water using a fork for the purpose. When well mixed, turn out on a well-floured board, or slab, and knead from five to ten minutes; form into little rolls, and place on a baking sheet or in American patty-pans, and bake in good oven from twenty minutes to thirty minutes.

Those who know the effects of salt will omit its use in bread. W.

NOTES AND REPLIES.

Strawberries.—Although tons of Strawberries are annually consumed with apparently little harm to the majority, it would appear there are a few people on whom they act with a very prejudicial effect, and the recent notes on the subject in GARDENING ILLUSTRATED lead to the inference that the ill-effects might be considerably obviated if raisers of new varieties would eliminate all the acid, watery sorts. One of the worst in this direction in bygone days was Trollope's Victoria, and in a less degree Kitley's Goliath, a huge fruit not so acid as Victoria, but decidedly watery and with very little flavour. Noble, a sort much in request for a time on account of its earliness, was very little better from a flavour standpoint. I thought it inferior to Goliath. River's Royal Hautbois, Lady Suffield, and Doctor Hogg might be tried by those anxious not to forego a treat of Strawberries if difficulty has been experienced with other varieties. Probably one of the worst of the present day, so far as acidity is concerned, is Sir Charles Napier. One of the older sorts that was always favourably received and from which no after ill-effect (or, at any rate, very little) was experienced was Myatt's Eliza, but I have

not seen it for many years, and believe it has been superseded by River's Eliza, but whether this has the rich flavour of its predecessor I am unable to say. I suppose few remember a later Strawberry season than the present one. The spell of cold weather experienced in late spring is doubtless responsible for this, but once expanded the blossom in the majority of cases came through safely, and so, although late, the crop is likely to be a good one.—E. B. S., *Hardwick*.

Turnips boiled in milk.—A very appetising vegetarian dish may be thus prepared. Wash and brush some Turnips in cold water, and pare away the thick skin. Cut the pared Turnips into oblong pieces and let them remain in cold water till they are to be cooked. Then put them into boiling water with a little salt, and boil them till they are slightly soft; drain off the water and nearly cover the Turnips with milk. In this milk let them boil till quite tender, but the pieces must not break, or they would look unsightly. When cooked, place them in a vegetable dish, add a piece of butter to the milk, and thicken with flour, seasoning with pepper and salt. Boil for another few minutes and pour over the Turnips, or, better still, return the Turnips to the sauce, leaving it at the side of the fire to keep hot until required for use.

Parsley.—When sowing Parsley to stand the winter a plain-leaved variety will be found superior to the curled or mossy sorts. The latter, no doubt, are the handsomer, but the leaves retain both snow and rain, and when frost follows, the plants soon succumb. On the other hand, a plain-leaved Parsley is far hardier and will survive even a severe winter. It certainly is not so attractive for garnishing as the curled variety, but for cooking, what signifies appearance if flavour be correct? Double the trouble is experienced in obtaining a supply of Parsley during winter, when only the curled-leaved varieties are grown.—Kirk.

The best gingerbread I know.— $\frac{1}{2}$ lb. brown sugar, $\frac{1}{2}$ lb. fresh butter, $\frac{1}{2}$ pint of milk, 1 lb. flour, 1 lb. black treacle, 1 dessertspoonful of ground ginger, 1 dessertspoonful mixed spice, $\frac{1}{2}$ teaspoonful carbonate of soda, 4 eggs, a little finely-chopped citron peel. Mix all dry ingredients together, warm the milk, dissolve the butter in it, beat up the eggs, then add the milk, and treacle. Bake three-quarters of an hour in a square cake tin, not very deep, or flat saucepan. The mixture should be quite a running consistency before baking; add a little milk if necessary. This is a moist, black ginger-bread.—S.

Grape Mrs. Pince in April.—It is doubtful if we have another late Grape with so high a flavour as Mrs. Pince. Early in April a friend sent me a bunch—about a pound. I do not remember ever having seen any late Grape so well preserved and having so much flavour. Lady Downe's is good, but it is eclipsed by Mrs. Pince in flavour. The Mrs. Pince was grown in a house with Muscats, allowing six or eight eyes to remain and not depending on spurs.—J. C. F. C.

Egyptian Coffee.—The Coffee berries must be freshly roasted, then pounded to a powder, not ground. About a dessertspoonful of the powder is used to two tablespoonfuls of water. The powder is put into the Coffee-pot, which is nearly filled with water, and put over a slow fire and brought to the boil. As soon as it begins to boil draw it off the fire, then replace it and bring to the boil again; repeat this, and it is then ready to serve. In Egypt they seem to drink the grounds with the liquid, but we generally prefer to let it stand a minute to let the sediment settle before pouring it into the cups. It should be drunk without sugar and milk.—*Queen*.

[It should be added that the Coffee is the true Mocha, a kind not always to be had in the shops.]

W. S. DINARICA (syn. *W. Pumiliorum*) is a less beautiful plant than the type, having large, purple, bell-shaped blossoms. It is of easy culture and a very desirable plant.

Other members of the genus include *W. Kitabeli* and its variety *W. K. croatica*, *W. graminifolia*, and *W. tenuifolia*.

E. H. JENKINS.

—Mr. F. W. Gallop, to whom we are indebted for the photograph from which the illustration was prepared, writes as follows:—

"This is one of the most beautiful of this family, and is in every respect an ideal plant for the rock garden, producing a perfect sheet of purple-violet cups. Deep fissures of gritty loam and a rather sunny aspect on a ledge in the rock garden so that its creeping branches of Thyme-like leaves may spread over the rocks suit it well."

WATER LILIES IN TUBS.

CAN you kindly give me advice about Water Lilies in tubs? I wanted to grow these in this way in the rock garden in four round tubs, about 2 feet 6 inches wide and 18 inches deep. Good kinds of Lilies were put in in May, and they came away all right, but went back after making a fair growth. So as not to lose them, I took them out and planted them in a shallow pond. In tubs, ought the water to be constantly changed or only filled up. In two of the tubs it became a thick, green, smelling filth, and in the other two, in which the Lilies did better, it remained fairly clear. I simply planted the Lilies in baskets in good loam and set loam all round the baskets, about 6 inches to 9 inches, and then filled up with fresh rain-water, and kept them full. As they began to look so bad, I took them out this past week. The tubs are old barrels, and I am not sure what they had been used for. Two (the ones the water went very green in) were tarred in winter, but have stood with water in them ever since, and it was changed constantly in all till the Lilies were planted.—C. A. HOPE.

[The growing of Water Lilies either in tubs or shallow receptacles of any kind is not infrequently attended with both difficulty and disappointment. The water question is a difficult one, and unless there is a supply arranged, and tubs connected with each other, so that a certain amount of circulation is set up, not much success is assured. Tub s are best set in the ground—sunk nearly to the brim—open zinc or other gullies conveying the water. Starting with the first raised a few inches higher than the rest, the arrangement would present no difficulty, and sides of the tubs could be easily shrouded by plants. The water in isolated tubs invariably quickly becomes stagnant, and often evil smelling to boot. All tubs before being used for this purpose should have been first burned—i.e., charred. No tarring is necessary, indeed, it is a mistake. Good loam surrounded by clean gravel stones or pieces of limestone is all that is necessary in the way of soil. Manure should not be used, as it favours, during the process of decomposition, the formation of green scum and other like matter. Rain water, if you have a good supply, is best, and adding sufficient to cause a considerable overflow of the tubs once weekly should keep it fairly clear. The varieties of *Nymphaea odorata* would be best for your purpose. In future, when sending queries, please write on one side of the paper only.]

Phujopsis stylosa.—This is very useful for bare places at the top of the wall garden or banks, and may be used in the rock garden or border, where it soon spreads. It flowers very freely from May to August if the soil given it be fairly light. The flowers are of a rose colour, rather pale, but quite pretty.—E. T. ELLIS, *Wetwood, Ecclesall, Sheffield*.

OUTDOOR PLANTS.

LONGLEAT.

At this season of the year, when Rhododendrons and the hardy Azaleas are in full bloom, Longleat, with its well-kept roads, affords pleasure to thousands of visitors, who come from long distances attracted thereto by the beauty of this vast tree-clad estate, which its owner, the Marquis of Bath, throws open to everyone on foot or on wheel. "Heaven's Gate" has been made famous by the poet Crabbe, whose centenary has just been celebrated. This beautiful spot is on an elevated ridge overlooking the park and many square miles of distant country. Nothing, however, one could write could even vaguely express the natural grandeur of Longleat. Our purpose was not so much to write of these natural pictures,

ones. Owing to the war only the elder workmen and quite young lads are employed, but despite the shortness of labour the condition of the gardens in their several departments is well maintained, and quite a varied lot of plants occupies the glass department. Melons, once largely grown, have naturally fallen behind. We can remember years ago Melons grown on the extension system showing fruit in every stage from the flower to the matured fruit, numbering, perhaps, two dozen on a plant. This extension system has fallen into abeyance of late years, and the more orthodox custom followed. Cucumbers and Tomatoes are now, as in past times, grown freely and well. Among the Peaches are some very old trees that have borne good crops of highly-coloured fruits for, it is said, over eighty years, and yet are as vigorous and fruitful as at any time in their long history. This speaks

R. F. Felton, Lucy, Mary Allwood, and a nice border variety named Lady Hermione, which has a Clove fragrance, were remarked. Malmaison Carnations are grown, but their propensity to disease may lead to their non-cultivation, since labour shortage allows of no margin for special treatment. Salpiglossis sown in late autumn has been remarkably effective and highly prized for decoration, the varied and beautiful colour markings making it much more desirable in early spring than outdoors in late summer. These remarks apply to other annuals that are adapted to pot culture. Another annual that has been much admired is *Asperula azurea setosa*, this doing well in comparatively small pots. *Schizanthus retusus* was bright and good, and *Humea elegans* appears to grow as freely as weeds. Harrison's Musk, *Primula malacoides*, Cyclamens, herbaceous Calceo-

Longleat, the Wiltshire residence of the Marquis of Bath.

but rather to renew an acquaintance with its gardens.

We distinctly recollect visiting these gardens more than thirty years ago. The man who made Longleat famous was Mr. Wm. Taylor, who still survives his three successors. He it was who gave Longleat Gardens their highest fame by the erection of the great vinery. This famous structure, once filled in three sections by twelve Vines, its length 220 feet and its width 30 feet, became a source of education to both old and young as to the extension system of training. The substitution of Palms, Bamboos, and other tropical plants for Hamburgh Grapes, to which a section has now been devoted, detracts from the dignity of the structure. The introduction of plants brought the dreaded Vine pest, mealy bug, its baneful influence contributing, no doubt, in a great measure to the debility of two of the four Muscat Vines, which have been replaced by young

volumes for the care bestowed on them and the fertile soil in which they are grown. There are, naturally, some occupants of recent time and some older trees that are destined for removal. The older trees are those which have been forced year after year, and they each cover considerable space with apparently no sign of branch debility, and the crop this year is quite a heavy one. Pot-trees afford early pickings. These are almost finished for this season, and Figs in pots occupy the same structure.

In the plant-houses Carnations occupy much space and are grown remarkably well in not over-large pots. Some 1,500 plants give an abundance of cut bloom at all seasons. We were impressed with the pure yellow of Improved Cecilia, its vigorous growth, and marked succession of buds. Salome, Mrs. Chas. Knopf, Carola, Scarlet Glow, Mikado, Mrs. Dutton, Circe, Washington, Colossus,

larias, Begonia Gloire de Sceaux, and B. Gloire de Lorraine, are other plants grown remarkably well.

About 700 Strawberries are grown in pots, and these at the time of our visit were in various stages of growth and ripening, while earlier batches were over. The fruit crops are variable on walls and in the open. Peaches appear to have set freely, and are swelling up very well. Plums also appear to give promise of a good yield, but Apples are thin and many Pear-trees carried no fruit. Strawberries are limited to four varieties. Newton Seedling appears to be a distinct late-fruited variety, Laxton's Latest is being tried, while Royal Sovereign and Vicomtesse supply the maincrop. Figs fruit uncommonly well on the walls and attain to a large size, Brown Turkey being the favourite variety.

The vegetable garden, enclosed by high walls, extends to about six acres. Large

plots outside, formerly cropped with Potatoes, have since the war been sown down, the depletion of the staff compelling this limitation. Much trouble is experienced with pheasants, which attack Peas, Broad Beans, and even Runner Beans, clearing sometimes whole rows completely.

The central walk of the kitchen garden is in summer gay with herbaceous plants, wide borders being of late years set apart for them, backed by espalier-trees, trained on wire. Apples, mostly, are thus grown, and, we believe, bear well. Quite a large area is devoted to flowers in the flower garden proper, and the preparation of summer bedding plants imposes a heavy tax on the resources of the garden.

Much credit is due to Mr. Barter for the upkeep of the garden, considering the limitation of the staff, particularly in the glass department, which is worked by young lads only. W. STRUGNELL.

HARDY FLOWER NOTES.

ALSTREMERIA AURANTIACA.—The cultivation of some hardy plants would puzzle the most experienced grower to explain. I had a bed of this Peruvian Lily which bloomed very freely annually and which had been undisturbed for some years. There came a demand for it, and the greater portion of the roots was lifted. As they had been growing in poor soil and not in a very good position I thought I would give the remainder a better chance, and transplanted on to good ground. Hardly a plant appeared, and the following year the same thing happened. I thought that I had removed all the roots, but this was not the case, for this season, nearly three years later, young growths have appeared quite plentifully. If a root here and there had started it would not be so strange, but that every root should refuse to push into growth for so long a period and then make a fresh start is very puzzling. Where this *Alstroemeria* is suited in the matter of soil it grows like a weed and is a very showy thing and very fine for cutting.

ROCKERS.—One advantage of a garden which is not conducted on very precise and tidy lines is that frequently natural conditions favourable to the continuous existence of some particular hardy plant without causing trouble to the owner are set up. The single Rocket is a case in point. In a border which is allowed to run a bit wild this Rocket has become naturalised. It was planted a good many years ago, but no effort at propagation has been made from that time until now. The plants seed, and young ones spring up, which in a general way are allowed to remain, and they bloom evidently with native vigour. This year they are very fine, the moisture and cool atmosphere having apparently suited them. A pleasing feature of it is that hardly two plants bear flowers of the same tint, as they vary from almost white to a mauve-pink. Where there is a demand for cut flowers the Rocket will help to fill the basket at a minimum of cost. The double varieties are fine, but they need good culture if they are to take up a permanent residence in the garden. In a heavy moisture-holding soil they are unhappy and pine; in a very light soil they are apt to suffer badly, the strain of producing a full crop of bloom bringing them into a semi-exhausted condition from which they never recover. Biennial transplanting into fairly rich ground with a mulch of rotten manure in summer will, however, maintain them in vigour. They should be planted in autumn, not later than mid-October, or

in early spring; never in the depth of winter.

CAMPANULA MURALIS.—What a valuable little hardy plant this is, so easily pleased, making no demand on the cultural resources of the owner. A little mound of soil studded with stones forms a happy home, where it will remain quite content for years.

SAXIFRAGES IN SUMMER.—The trying time for this large family of hardy plants is approaching. Some, such as *S. pyramidalis* and *altissima*, are able to bear much drought without flinching, but the majority are liable to injury during a period of heat and drought. Watering will, of course, counteract this, but there are always more things that need watering than can be properly attended to, and rock plants are apt to suffer. If they do not die the seeds of decay are sown, the wet and cold of the following winter completing the mischief. A top-dressing of leaf-soil is a fine thing at this time of year, and I do not know an alpine which is not benefited by it. In the case of the encrusted kinds it should be worked well in among the growths, this causing new roots to be made from the crowns. August is supposed to be the most trying month for vegetation, but July I consider the most dangerous time, for surface-rooting plants do not belong to the more robust-habited forms of vegetation. The days are long and the nights are generally dry, whereas in August the resting hours are extended, and it is characteristic of our climate that we get heavy dews in that month, and these are very refreshing.

J. CORNHILL.

NOTES AND REPLIES.

Planting herbaceous border.—I wish to make a new herbaceous border late this autumn of, or about, 10 feet wide and from 40 feet to 50 feet long. I want plan of same. This border will face almost due south, and I should like, if possible, to have a permanent coloured border from April to October. I have quantities of beautiful old-fashioned herbaceous plants which I wish to remove. What would be the best time and the best way of removing same?—BOG-CORTON.

*[It is much better not to work from a plan, as plans usually lead to stereotyped effects. Make the border to suit your taste and plant whatever you are most devoted to and have the best selection of. Many plants in mixed borders are quite unfitted for them, and should be excluded. Do not work to have things all in flower at the same time; that prevents some of the finest plants being used. Plants like *Acanthus* look well when out of flower. The soil should be at least 2½ feet deep. Avoid putting things in lines, and group the plants together—say, five to a dozen or more—and let greys predominate as much as you can. Give good place to the best plants of recent coming, like the *Azure Sage* (*Perovskia*) and the *Californian Tree Poppy* (*Romneya*).—Ed.]*

Lifting English and Spanish Irises.—Will English and Spanish Irises, if moved every two years, go on for ever, or will they deteriorate?—H. T. SHAWCROSS.

[If the Spanish and English Irises are being grown in the heavy soil referred to they would be best if lifted and rested annually, though the English kinds often improve in the second year in suitable soil. The lifting should be done at the end of July, the replanting in October, resting the bulbs meanwhile in an airy and dry place sheltered from sun, and cleaning them before replanting.]

The Basil-leaved Soapwort (*Saponaria ocyroides*).—This does not always stand the winter, but I think this is largely owing to the soil and exposure. I have

observed that the plants most liable to perish are those in the lower parts of the garden and not fully exposed to sun and air. A dry soil with free drainage is the most suitable. I have not lost a plant during the past winter, and now quite a number of large specimens is in full bloom, giving sheets of warm pink. Self-sown seedlings appear in considerable numbers, and from among these may be selected some good forms to be propagated from cuttings, although seedlings make the more vigorous plants.—S. ARNOTT.

Primula Bulleyana.—This, one of the moisture-loving species, is now blooming freely, the wet winter and spring which we have had having suited it very well. It is quite hardy and does well in my London garden in a shady border made up of gritty leaf-mould mixed with well-decayed garden refuse, though it is, perhaps, not so fine as when grown in a wet spot. I find, however, that a deeply-dug soil with the surface kept well hoed does much to help those plants which need moisture, and pieces of stone buried about the roots still further assist. The flowers of *P. Bulleyana* are borne in tiers, as in the case of *P. japonica* and *P. pulverulenta*, but, unlike those species, the colour is a sort of ochreous yellow, the unopened buds being of a deep orange-red. It grows freely from seed, especially if sown as soon as ripe in a shaded, moist place.—NORTH LONDON.

Plant losses in the winter of 1915-1916.—It is rather strange that the losses among many things considered hardy should have been much heavier as the result of the winter of 1915-1916 than is usually the case, especially when up to the second week of February of the present year hardly any exceptionally cold weather had been experienced. It was before this that the mischief was done, because, looking through the border at quite the beginning of February, I found the majority of the *Antirrhinums*, *Chrysanthemums*, and several *Fuchsias* had succumbed, and this, too, in a fairly sheltered position. It is specially strange in the case of the *Antirrhinums*, as they have been in the same quarters many years, and hitherto invariably broken away strongly. It was a good strain, and there is, fortunately, a good batch of seedlings to take their place. I found it useless to leave *Lobelia cardinalis* outside through the winter, so plants of this did not share the fate of other things, and are now making nice headway in association with Pinks.—E. B. S., Hardwick.

Geum Mrs. Bradshaw.—Groups of this pretty border plant have made a gorgeous show for some weeks past. Seeds should now be sown to furnish plants for flowering next spring. The seeds should be sown in boxes filled with light compost, and the soil watered with a fine rose-can. Stand the seed-boxes in a cold frame and keep them shaded until the seeds have germinated. When the seedlings are large enough pot them singly into 3-inch pots and plunge in ashes in a cold frame, where they may remain for the winter. If another sowing be made in the autumn it will furnish plants for flowering later.

Gaillardia grandiflora.—I consider this one of the best of all *Gaillardias*. The flowers are of orange, yellow, or red, and are beautifully marked. This plant will soon be in bloom now, but it comes to its best here in July and August. It is grand for cutting, and with good treatment grows into a small bush 2 feet to 4 feet high. I find it does best in light shade, and it must have plenty of water in hot weather.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

Veronica amethystina.—This is hardly suitable for a small rock garden, as it grows about a foot high and makes a big, spreading clump. The spikes of flowers are of a brilliant deep blue, similar to those of *V. Teucrium dubia*, but larger. It grows rapidly and is quite an easy doer in a sunny position, and can be increased readily by tearing the clump to pieces and planting the rooted pieces.—W. O.

ROOM AND WINDOW.

PYRUS FLORIBUNDA.

THIS is now well known, but its flowering in the open air is, as with so many plants of the Apple tribe, rather apt to be short and interfered with by storms and other accidents. It is well, therefore, to gather the handsome shoots of this and others of its allies before the flowers are fully open and use them in the house, where they are very effective, as in this case.

ORCHIDS.

NOTES AND REPLIES.

Odontoglossum citrosimum.—This produces its drooping racemes of rose-pink coloured flowers during May. When the spikes are removed the plants will be in

spikes are seen, then the supply can be increased gradually. The pseudo-bulbs will shrivel slightly during the resting season, but no anxiety need be felt, as they soon recover when the time arrives to water the roots freely.—SADOX.

Miltonia vexillaria.—During May and June the various forms of this showy Orchid are in bloom. After flowering, a short period of rest should be allowed, placing the plants in the cool-house, and giving only sufficient water to keep the soil just moist. After this treatment has continued for six or eight weeks they may be repotted in a mixture of Osmunda-fibre, Polypodium-fibre, and Sphagnum Moss in equal parts, while a few partly-decayed Beech leaves may be added if the plants are not thriving. Fairly deep pans may be chosen, and, as *Miltonia vexillaria* is more or less a surface-rooting subject, they must be filled to one-half of their depth

mountains in 1899, and last year I had some lovely varieties of *C. ventricosum*, which is much more vigorous and striking. But at present I do not know how to treat them, or where to plant them, and it seems very much a matter of chance whether most of these *Cypripediums* live or die. Mr. Irving, however, has got *C. ventricosum* established on the top of the Kew rockery facing north-west, where its white form was, to my mind, the choicest thing on the whole rockery recently, and I have got a fine form of *C. Calceolus* which I brought from Arctic Norway in 1905 still flourishing. — H. J. ELWES in *Gardeners' Chronicle*.

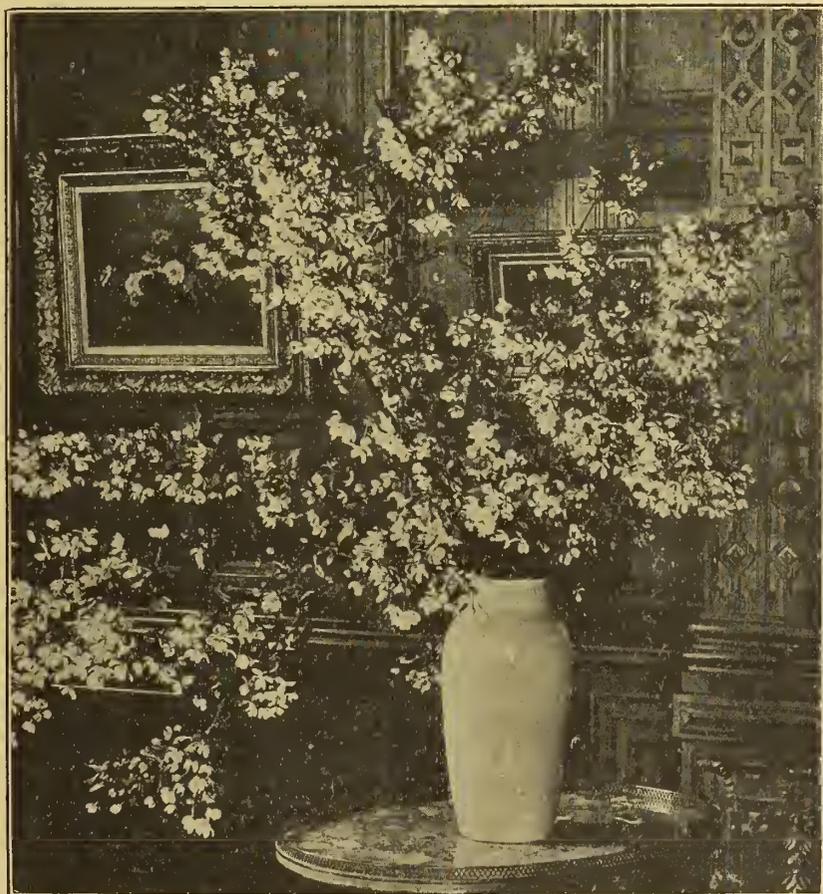

VEGETABLES.

SUMMER CARROTS.

I HAVE for some time abandoned the extensive cultivation of the big Carrot, and instead maintain a supply of small, tender roots by frequent small sowings. The seeds in showery weather germinate quickly, and soon develop into edible roots, and even in winter one may pull these from the open ground and thus preserve the sweet and delicate flavour of the summer Carrot. For flavouring and for garnishing, for which the Carrot is largely drawn upon in many households, probably a small sowing of the larger type may be economical, because these may be lifted and stored in a dry shed and be handy for daily use. It may be argued that the Short Horn is just as well adapted to this purpose as the larger root: I know this is quite possible, but there is undoubtedly a considerable amount of waste when large Carrots are sent to the kitchen.

Carrots are sometimes seriously injured by the garden slug. I have known instances where Carrots which had germinated well, the lines being distinctly seen, suddenly disappeared. Soot scattered over the bed thinly and frequently makes the leaves distasteful, and a good dusting of dry road-sweepings is helpful in warding off an attack if threatened. In the clearing of the ground of summer crops, Peas or Potatoes, for instance, there is ground quite ready for the reception of Carrots at any time up to the month of September. In this way ground that in the ordinary way would be given over to Carrots could be more profitably devoted to Potatoes, the early varieties of which would be cleared in time to sow successional batches. There are several kinds of the short-rooted Carrot, Early Nantes being a very general favourite. Carter's Golden Ball and Long Forcing I find early maturing. Early Gem and Summer Favourite are other good stocks of a quick-maturing character. Young Carrots are so much appreciated in many households that gardeners devote much time to forcing them in order to get them in early. No one will deny they are well worth this extra labour. In the market young Carrots find a ready sale, but to keep up a good supply it is necessary to make frequent sowings. Short Horn Carrots will become coarse and lose their flavour if allowed to get overgrown, hence the necessity for frequent sowing. W. STRUGNELL.

Turnips.—As Turnips are soon over after they become ready for use, especially during the early part of the summer, seeds must be sown frequently, and in small quantities. During July and the early part of August it will be necessary to sow in larger quantities and greater variety, because from these sowings the autumn and winter supplies will be obtained.

Sprays of Pyrus floribunda in a jar.

a fit condition for repotting if the compost is at all decomposed. Teak-wood baskets or pans are the most suitable, and a wire handle should be attached whereby they may be suspended near the roof-glass of the Cattleya-house. Each basket or pan should be filled to one-half of its depth with drainage material, over which is placed a thin layer of rough compost to secure a free outlet for water. The compost should consist of three parts Osmunda fibre and one part Sphagnum Moss, both cut up fairly fine. Press the soil moderately firm. Throughout the growing period afford liberal supplies of moisture at the root, but when the pseudo-bulbs are fully developed very little water will suffice. To obtain a full complement of scapes it is essential that the pseudo-bulbs be thoroughly ripened. When the plants commence to grow in the spring, water must be nearly withheld until the flower-

with drainage material. The soil should be made moderately firm about the roots, and it ought not to be raised above the rim of the pan. Arrange the plants near the glass of the intermediate-house. Give sufficient water to wet the whole of the soil, and then just sufficient to keep the compost moist. When root-action increases, water may be given more liberally.—SADOX.

Hardy Ladies' Slippers.—Hardy terrestrial Orchids are usually supposed to be difficult to grow, and still more so to keep, but if people would give them a little of the care and skill that they give to hot-house Orchids we should soon find out the secrets of their life-history. I have managed to keep alive for sixteen years and to flower several times one of the rarest and prettiest of the hardy *Cypripediums*, namely *C. guttatum*, which I found in the pathless forest of the Altai

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM JUNE 28TH.—*Aubrietias* (in variety), *Mossy and Encrusted Saxifrages* (in variety), *Antirrhinum Asarina*, *A. glutinosum*, *Ethionemas* (in variety), *Alyssums*, *Androsaces* (in variety), *Andromeda polifolia*, *Aster alpinus* (in variety), *Aquilegia* (in variety), *Armerias*, *Onosma tauricum*, *Convulvulus Cneorum*, *Globularia nana*, *Lewisia Howelli*, *Suponaria ocyroides*, *S. cæspitosa*, *Campanulas* (many varieties), *Dianthus* (in great variety), *Ramonda pulegioides*, *Alpine Phloxes* (in variety), *Primulas* (in variety), *Cheiranthus* (in variety), *Lycnis Viscaria splendens*, *Veronicas* (in great variety), *Oralis cneaphylla*, *Heeria elegans*, *Lithospermums* (in variety), *Helianthemums* (in variety), *Cistus* (in variety), *Mecanopsis*, *Geums*, *Erinus*, *Mule Pinks*, *Dryas octopetala*, *Silene alpestris*, *Sempervivums*, *Thalictrum aquilegifolium*, *Thymes* (in variety), *Ourisia coccinea*, *Tradescantia virginiana rubra*, *Asperula nitida*, *Sedums* (in variety), *Arenarias*, *Gypsophilas* (in variety), *Omphalodes cappadocica*, *Incarvillea Delavayi*, *Heucheras*, *Gladiolus byzantinus*, *Eremurus robustus*, *E. Bungei*, *Delphiniums*, *East Lothian Stocks*, *Liliums* (in variety), *Pyrethrums* (in variety), *Lupinus arboreus*, *L. polyphyllus*, *Nepeta Mussini*, *Iris* (many varieties), *Drimys Winteri*, *Tricuspidaria lanceolata*, *Schizophragma hydrangeoides* (Climbing *Hydrangea*), *Solanum crispum*, *Clematis* (many species and varieties), *Roses* (many species and varieties), *Senecio Greyi*, *Olearia macrodonta*, *O. Gunniana*, *Ozothamnus rosmarinifolius*, *Deutzias*, *Abutilon vitifolium*, *Grevillea rosmarinifolia*, *Philadelphus*, *Rodgersia podophylla*, *Romneya Coulteri*, *Anchusas*, *Cypripedium spectabile*, *Nymphaeas*, *Butomus umbellatus*, *Aponogeton*, *Spiraea Aruncus*.

WORK OF THE WEEK.—Where watering has been necessary, the ground has been gone over and the surface-soil stirred to break the crust, afterwards mulching where practicable with decayed leaf-soil. *Phlox Drummondii*, *Verbenas*, and trailing plants generally have been pegged down. Staking is an important item at present. All plants are staked in as natural a manner as possible, displaying as little of the supports as is practicable. Tall-growing herbaceous plants must be supported before the growth is too far advanced. Climbers are given an occasional look over to prevent the young growths becoming entangled or the strong shoots getting broken, at the same time thinning out weak spray where too thick. Late-sown annuals have been finally thinned, and a further sowing of *Mignonette* made on a shady border. Many alpine which are passing out of flower have been cut back, except in cases where seed is required. The propagation of various plants is carried out as cuttings become ready. Cuttings of most plants root readily in a bed of sand placed in a cold frame. The sand is kept constantly moist by sprinkling with a rose-can three or four times daily. The frame is kept quite close, and no shading whatever given. On no account must the sand be allowed to become in the least dry. Cuttings of the following have been put in during the week:—*Aubrietia* (in variety), *Dianthus* (in variety), *Phlox subulata* vars., *Phlox Laphami*, *Onosmas*, *Saxifrages*, *Frankenia laevis*, *Malvastrum lateritium*, *Pentstemon Scouleri*, *Ononis fruticosa*, *Daphne Cneorum*, *Rosmarinus prostratus*. F. W. G. *Northants*.

SOUTHERN COUNTIES.

Shrub-pruning.—Whatever pruning early-flowering shrubs may require should be done now, and not left till the winter, as this occasions much loss of bloom. *Lilacs* and *Mock Oranges*, as soon as they pass out of flower, *Gelder Roses*, etc., come under this heading. The seed vessels should also be removed from the choicer varieties of *Rhododendrons*, *Azalea mollis*, and their hybrids; also *Ghent Azaleas*. *Wistarias* need to have their young growths stopped at this season, not only for appearance sake, but that flower-buds may set on the lower portion of the spurs. The young growths on the *Virginian Creeper*, where they would lead to an obstruction of light, should

be cut away from around windows, otherwise they should be left for the sake of the effect produced by the foliage when it changes colour in autumn. As soon as the leaves fall these superfluous growths can then be removed. The strong growths should be cut out from summer-flowering *Jasmines*, as these do not bloom and are not needed on established plants. Vigorous growths on *Tea* and other *Roses* trained against walls should be looked after and fastened back before they get blown about and broken by rough winds. *Hedges of Tree Box* are best clipped at this date, when they will retain a neat and tidy appearance throughout the remainder of the season. The clipping of *Box* edgings to walks, though best carried out in May, can yet be done. The common *Laurel*, where grown to shut out unsightly objects, should have the young growths cut back to keep them within bounds as well as furnished at the base. This is best done with a knife.

Early Peach-house.—Directly all the fruit has been gathered the trees should be looked over and the old bearing wood, as far as possible, cut out. This will allow of more space being devoted to next season's bearing wood, which should at the same time be regulated and tied to the trellis. The admission of a greater volume of air and light which results from this mode of treatment is always reflected in the character of the young wood when autumn arrives, inasmuch as it is always more perfectly ripened and studded with fruit-buds than when this little extra amount of trouble is omitted. The house must also be ventilated to its fullest extent, and as it is essential that the foliage be allowed to die a natural death, so to speak, it must not be allowed to fall a prey to insect pests. The worst of these is red-spider. If this has already gained a footing, sulphur mixed with soft-soap and water should be applied. After this a vigorous hosing or syringing of the trees will keep this foe at bay. The border, as heretofore, must be regularly attended to in the way of watering, and old trees may have an occasional soaking of liquid manure.

Second house.—The colouring of the fruits is the signal to commence modifying the treatment by gradually diminishing the amount of atmospheric moisture and substituting warm, dry air for it instead. After so much dull weather *Nectarines* must be carefully looked after, as intense sunlight will damage the exposed portions of the fruits. Some varieties are more susceptible to scalding than others, but it is always wise, especially when the houses are of modern construction, and the trellis situated no great distance from the glass, to apply a light shade as soon as the fruits commence to colour.

Late house.—Unless necessary to forward the crop in order to have the fruit ripe by a certain date, the house should be freely aired, reducing the amount of ventilation only in dull weather and at night when damp and chilly. On bright days the paths and borders should be frequently damped and the trees subjected to a good washing every morning and afternoon. Border watering must have regular attention and stimulants afforded according to the age and vigour of the trees.

Frame Melons.—Plants showing a good number of female flowers should be kept rather on the dry side until more than sufficient have opened and are set. Syringing, too, must be suspended for the time being, as a perfectly dry atmosphere is necessary to ensure success. Fertilisation will occupy a few days, and as soon as a good set has resulted a soaking of tepid water will swell out the fruits. As they gain size leave four of the most promising on each plant and elevate them on pieces of slate laid on inverted flower-pots. To concentrate the full vigour of the plants on fruit production alone, all lateral growths produced beyond where stopping is done at the time of setting should be kept closely pinched in. The mounds of compost must be added to the margins, but not round the stems of the plants, to keep the roots active and the fruits swelling. Settle the fresh compost into place with a free supply of tepid water. Syringing must be carried out in accordance with weather conditions, and the frames closed sufficiently early to secure a temperature of 85 degs. to 90 degs.

Cucumbers.—Plants growing in frames need a look over twice weekly, when thinning and stopping of growths should have prompt attention. Avoid over-cropping, and remove all deformed fruits before they have time to develop. Top-dress the roots on the little-and-often principle to encourage the production of quantities of new roots and to maintain the plants in a vigorous condition. As with *Melons*, syringing must be regulated according to the weather, and closing for the day done as early as is compatible with safety, always remembering that no harm will result even if the thermometer registers a temperature of 90 degs. provided the plants are syringed at once with tepid water.

A. W.

MIDLAND COUNTIES.

Strawberries.—Strawberries are ripening very slowly. No Strawberry plantation should be retained after the fourth season of cropping. The most satisfactory method of renewing the Strawberry beds is to plant a given number of rows each year, and destroy a similar number of the old ones as soon as the fruits are gathered. As soon as strong runners are procurable they should be layered. A convenient method is to layer them into small pots, which enables them to be removed from the bed at an early date. The compost for layering may consist of good loam mixed with a little manure from a spent Mushroom bed. It is not necessary to crock the pots, some of the rougher particles of loam placed in the bottom being all that is necessary. Pegs may be used for layering or the runners may be kept in position by placing stones on them. The ideal runner is one with a stout single crown, moderate leaf stalk, and a good root system. Such plants ripen their crowns well in the autumn and fruit well the following season. Keep the layers growing whilst attached to the parent plant, and when well rooted transfer them to their permanent quarters. Only a few runners should be secured from each plant and the others cut off.

Bush fruits should be adequately protected from birds. Where they are planted in squares and not permanently protected by wire netting it is a good plan to fix stakes all around and across, about 6 feet high, with long poles or cord to fasten all together at such a distance that the net when stretched over them will not bag too much. This method gives easy access to the fruit, and the net also dries quicker after rain. If useless shoots have not been cut away, as formerly advised, it should be done before netting the bushes.

Herbaceous borders.—Everything possible should be done to make the flower borders neat and tidy. Remove the old flower-stems and any unsightly shoots. Stake where necessary, and secure any shoots that need tying. Keep down weeds, and promote a fine tilth on the surface by means of the Dutch hoe. Where the hoe cannot be employed, hand weeding must be practised. Plants that are dry at the roots should be given a thorough soaking of water and afterwards a mulch. The present is a suitable time for dividing the *Fritillaria* or *Crown Imperial*. *Fritillarias* grow well for a number of years undisturbed, but it is sometimes advantageous to thin them, and division is one of the easiest means of increasing the stock. *Herbaceous Pæonies* may also be divided at the present time.

Pinks.—It is advisable to raise a fresh stock of *Pinks* each season or the clumps become weak and straggly. This may be done now either by layering the Grass in the same manner as *Carnations* or by striking cuttings. I prefer the latter method. The cuttings should be pulled off the old plants, and, after trimming off the lower leaves, inserted in boxes of sandy soil and placed in a close frame for a week or two, shading from bright sunshine.

Roses.—Many of the climbing varieties will shortly need overhauling. All faded flowers should be removed. Any that have finished blooming should have the old flowering shoots cut out and the young growths trained in their places. Be careful not to injure the stout basal growths, as these will form the flowering branches for next season. In the

case of Hybrid Perpetual Roses, the appearance of the Rose garden will be enhanced if the plants are gone over once a week and the petals of faded blooms removed before they fall.

Azalea indica.—Plants that were forced and which after flowering were put into heat to complete their growth have now matured their buds sufficiently to allow the plants to be gradually hardened and placed out-of-doors. They will be placed in a position that is partially shaded during the hottest parts of the day, plunging the pots in ashes to keep the roots at an equable temperature and to prevent them drying quickly. Water with care and syringe the plants thoroughly every fine evening, using occasionally some clear diluted soot water, this serving to ward off thrips and other insect pests.

Calanthes are now growing freely. Extra care in watering is necessary for these plants during dull weather, as the compost will not dry through so quickly as it otherwise would, and if kept in a saturated condition without sunshine the bulbs and leaves will become spotted. Keep the plants as near to the roof glass as is convenient, and as the season advances gradually accustom the most forward plants to a greater degree of light. Very little syringing or damping between the pots is done during dull weather. Where a number of young roots appears on the surface of the compost a thin layer of fibrous loam should be placed lightly over them, into which the roots will quickly penetrate.

Broccoli.—Plants intended for furnishing a supply in late spring will be put out as soon as the ground is ready, choosing an open situation where the soil is not excessively rich, in order to promote the growth of hardy plants to withstand the winter. The ground must be made very firm before the plants are put out, as more failures are due to planting late Broccoli on loose, rich soil than to any other cause. Sufficient space must be allowed between the rows to prevent the plants becoming drawn. If the weather is dry at the time of planting a good soaking of water must be given to each plant.

Carrots.—A good sowing of stump-rooted Carrots will now be made on a south border previously occupied with early Potatoes. Last year the best and cleanest roots for use in winter were obtained from a sowing made early in July. The drills are drawn at 9 inches apart and one inch deep. Thin the plants as soon as large enough, leaving a space of 4 inches between each plant. Give an occasional dusting of soot, and hoe the surface-soil frequently between the rows.

Celeriac (Turnip-rooted Celery) needs abundance of water, and, where practicable, manure water should be liberally afforded. Keep the foliage well dusted with soot and the surface-soil stirred frequently. All side shoots should be removed.

Shallots have done well, and are now ready for lifting. They will be spread out thinly in full sunshine to ripen, and should the weather be wet and unsettled they will be placed under cover where plenty of air can circulate about them. When perfectly dry they are stored, selecting the hardest and best matured bulbs for keeping until spring.

Onions that were raised in heat and planted out for furnishing extra large bulbs are making rapid progress. The surface-soil is kept hoed and free from weeds, and an abundance of water and liquid-manure is afforded to the roots.

Vegetable Marrows should be watered frequently, and all weak growth removed. Cut the fruits before the skins become hard. Further plantings may be made in some sheltered spot in order to keep up a supply of young Marrows as late in the season as possible.

Parsley should be thinned to a distance of from 8 inches to 10 inches apart. The surplus plants may, if required, be transplanted to a sheltered part of the garden. Stir the surface of the soil frequently and apply a dressing of soot. Make another good sowing now on a south border, where protection can be given in severe weather.

Radishes should be sown in a cool situation, and water afforded frequently. The best place

to grow Radishes in summer is in frames behind a north wall. The soil should be light and rich. Sow the seeds thinly.

F. W. GALLOP.

SCOTLAND.

Vegetable garden.—Favoured by suitable weather, further successional plantings of the various Brassicas were made in the course of the week. Frequent showers fell, and the young plants were got out under the best of conditions. Taking further advantage of the moist soil, more Celery was planted, the varieties put out being Grove Pink and Major Clarke's Red. The latter, if not one of the largest, is very hardy, firm, and solid, has a good flavour, and keeps well. Second-early Potatoes have now been moulded up. Both these and the earliest plantings are more than usually promising, growth having been rapid during the past few weeks. During the week a dressing of soot was given to Carrots. For some reason germination has been poor in the case of the maincrop varieties, and resowing will be necessary. On the other hand, the Early Horn sorts are coming away freely. In the Onion beds good progress is being made. During the present season there will be no striving after exceptionally large bulbs; but, at the same time, a little artificial manure will be applied from time to time. The quarter intended for Leeks was levelled in readiness for the reception of the young plants. This particular quarter was occupied by Celery last season, and is, therefore, in excellent heart. A supplementary sowing of Parsley was made, more Lettuces were put out, and another sowing was made. Birds are at times troublesome in respect of germinating Lettuces, and it becomes needful to protect them by netting until the seedlings are out of danger. Glohe Artichokes were mulched to keep the roots cool and to check evaporation.

Sweet Peas.—The flowers on the earliest-planted clumps are now showing colour—at about the usual time. The hlooms are always useful, and endure a long journey, when cut, exceptionally well. The stems are cut at their full length, and when possible the hlooms are taken just when they are on the point of expanding. Close picking is necessary if the display is to be prolonged. During the week the clumps in question were given a light dose of sulphate of ammonia, and, as they are in a position where they can be reached by the hose, the sulphate was well watered in. It is surprising how quickly Sweet Peas respond to a little feeding. Later plantings and sown-out lines are equally promising, but as they are in a more exposed situation, some bud-dropping has been noticed. This, however, is in no way alarming, being merely the result of the somewhat cold nights which have been rather frequent of late.

Fruit-trees in pots continue to make satisfactory progress. The syringe is being used twice a day, and this will continue until symptoms of ripening are noticed. Figs, allowed to come away naturally, are very encouraging, and now they are being freely fed, a change of stimulant being given from time to time. Nothing, I think, seems to suit them better than liquid from the tank given in a well-diluted state, and at frequent intervals. The surface of the pots, however, must be kept stirred up, for this liquid appears to clog the pores of the soil. Stopping is practised when the sixth leaf is developed, and when the first crop is picked, if the temperature be kept fairly high and moist, a very useful second crop may be expected.

Plant-houses.—Some promising pieces of double-flowering Begonias have been moved from 6-inch to 9-inch pots, in which they make very showy and massive specimens. Begonias, generally, I think, do not much appreciate stimulants, experiment showing that tubers which have been fed with chemical manure in solution do not keep so well in a dried state as those which have received nothing but soft water. Gloxinias, now on the point of flowering, will presently make a good display, and if it is necessary to increase the stock, leaf-cuttings taken now and inserted in a close propagating-case will soon root and form

useful little tubers. The final lot of Geeneras has been potted up. The corms are, meantime, put in threes into 5-inch pots, and if necessary they can be broken up at a later date. Shade is now a necessity, for not only does shading prolong the display, but, in addition, it certainly reduces the amount of water required. A good batch of Zonal Pelargoniums is now being permitted to flower. These will probably be at their best about mid-July. There is not, however, the same interest taken in flowering plants under glass at that period of the year—the attractions out-of-doors being preferred, and I think rightly so.

Winter-flowering plants.—Provision is being made for a sufficiency of winter-flowering plants, and in the course of the week a good number of different things was planted out. These include the various kinds of Salvias—*S. splendens*, *S. rutilans*, *S. lactiflora*, and a few plants of *S. Pride of Zurich*. The last is used to some extent for summer bedding, but a small number is usually reserved for pots, chiefly for providing cuttings in spring. Eupatoriums were also planted out, as was a number of late-struck Chrysanthemums. All these are put out on a south border with a sunny exposure, and, in a general way, make large and massive plants when the time comes to lift them at the end of September. If the roots are cut round with a spade a week or ten days before the plants are to be lifted for potting they experience no visible check, and are very useful over a long period. Cinerarias for early-winter flowering make good progress. If these can be plunged to the rims of the pots in a cold-frame with a northerly exposure the sashes may with advantage be entirely removed except during prolonged wet. Some year-old pieces of *Primula obconica* and *P. sinensis* were planted out in a comparatively shady place. These, lifted in late autumn and put into 6-inch or 7-inch pots, make very useful stuff, and if the hlooms are not so large as those from seedlings, they are much more freely produced, and throughout the summer the plants give no trouble whatever, a fact not to be lost sight of under the present condition of affairs.

Blooms for cutting.—Very useful just at the present time are various subjects to which reference has been made from time to time. These include the early-flowering Gladioli—*G. Colvillei albus*, *G. Ackermanni*, and a variety known as Blushing Bride. *Ixia* and *Sparaxis* are likewise available, and the Spanish Irises are turning in at a very useful time, and will be succeeded by the English varieties. As all these things are grown thickly in cold frames a large quantity of bloom can be secured with the expenditure of but little labour. I find it unnecessary to lift and replant these subjects annually. They do perfectly well if left undisturbed for four or five years if the heds are given an annual top-dressing of good, sifted leaf-mould.

Hardy fruit.—Thinning and disbudding are being attended to among Peaches and Nectarines, this work being spread over a considerable time. It has not been found possible to devote so much time as usual to the hardy wall fruit, and a slight outbreak of aphids in the case of Peaches was noticed during the week. This was promptly dealt with by dustings of Tobacco powder, and the hose is being used upon the infected trees. Some small amount of watering was done in the case of Pears and Plums protected by a wide glass coping. This coping, while advantageous in some respects, has its drawbacks during the summer, for if these trees are not watered from time to time and inspected occasionally, vermin of one kind or another is almost sure to obtain a footing. Pears in the open give indications of heavy crops, and while many of the trees are carrying a full load, it is noticeable that in some cases Apples will be scanty. This is more evident on trees of some age, younger specimens, more especially those on dwarfing stocks, being full of fruit. Morello Cherries have set very well, and from their position are not so liable to be attacked by any of the various pests which at times are apt to worry fruit-growers.

W. McGUIFFO.

Balmie Gardens, Kirkcudbright.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.

Naming plants.—All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.

Naming fruit.—Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.

PLANTS AND FLOWERS.

Lily of the Valley planting (Bog Cotton).—Early autumn is the best time to make a fresh bed. When preparing the fresh site, have the ground deeply trenched, adding as the work goes on plenty of manure and leaf-soil, if you can get it. Do this in good time so as to allow of the settling of the soil before planting. Keep the crowns well below the surface, and plant firmly. A mulch of manure is very beneficial during the winter.

Sedums and Crassula (Sedum).—Sedum glaucum, unless grown in large pots or in pans, would not be very effective, though in the small pot plants it is pretty enough. It is of the easiest cultivation in very gritty, perfectly drained soil, and in past days was largely used in carpet bedding arrangements. If the soil in the pots is made rather firm the surface could be covered by pricking single bits of the Sedum all over it, so that when grown together a dense growth would result. The plant is perfectly hardy. Crassula perfoliata is a tender or greenhouse sub-shrub, and does best in loam freely charged with old mortar. Not much water at the root is required. If you know Crassula coccinea, similar soil conditions suit the above. Mesembryanthemum falciforme is not an annual, but an evergreen greenhouse shrub having sub-erect, woody, and somewhat rigid stems. It grows 1½ feet or so high and bears pink-coloured flowers.

Asparagus plumosus, treatment of (Belgian).—You say nothing as to the treatment your plant which has been cut down has previously received, hence we can only assume that it has been grown in a pot in the greenhouse. If so, it would be an advantage to place it in a warmer structure to encourage the production of new shoots from the base. If you have not such a place available, put it in the warmest part of the greenhouse, and keep the soil fairly moist, but not too wet. With this treatment it will in all probability throw up shoots from the base, but it would have been much better had the cutting down been done in March or early April, a considerably longer growing season being thus ensured. The first part of your question refers to large roots of Asparagus plumosus. That would almost seem to imply that they are perhaps imported ones, lifted from the ground. If so, they should be potted in a mixture of loam, leaf-mould, and sand, and placed in the greenhouse. Large masses of roots may sometimes be divided before potting, and in this way the stock can be increased. Strong plants of this Asparagus, if

planted out in a prepared border in the greenhouse will grow freely, and in this way are useful for clothing a wall; pillar, or part of the roof of that structure.

Scarlet Lobelia in winter (R. Owens).—In some heavy and retentive soils the Scarlet Lobelia will pass through even severe winters unharmed in the border without the slightest protection. In other gardens herbaceous Lobelias are found to winter well in the border undisturbed if mulched with an inch or so of leaf-mould or Cocoanut-fibre, but in the majority of cases it will be found necessary to lift the clumps in the autumn, after the flower-stems have been cut off, placing them in boxes or pans and afterwards shaking a little fine soil into the interstices between the clumps. Treated in this manner they will pass the winter safely in a cold-frame from which the frost is excluded, requiring but little moisture until they are starting into growth in the spring, when they may be separated and planted out in the border. Single shoots which form after the flower-spikes have been removed may be taken off in the late autumn when they have formed their first leaves, placed in small pots, and grown on in the greenhouse.

TREES AND SHRUBS.

Leaf soil (F. M. G.).—The best of all leaf-soil is that made from Oak leaves, as these seem to be of a more woody nature than are larger leaves. Next to Oak come Spanish Chestnut, Beech, and Elm leaves. The evergreen Oak leaves will also be useful. The best of leaf-soil is that which has taken two years to thoroughly decompose.

VEGETABLES.

The Tree Onion (Miss Ross).—Instead of a cluster of small bulbs of a brown-red colour, from which the plant is propagated. When planted in the spring these small bulbs form large ones by the end of the year, but do not produce any bulblets till the following year. The flesh of the Tree Onion is agreeable, but rather deficient of delicacy of flavour. The bulbs soon decay, but the bulblets keep very well.

SHORT REPLIES.

Lancashire Lad.—If you can get sheep-manure and immerse it in a bag in a tub of water, when using diluting it to the colour of pale ale, you will find nothing better for Chrysanthemums.—**Riduna.**—The tipping of Broad Beans has two advantages. One is that the tipping clears off the black-fly that congregates on the points of the shoots, and the other is that by so doing the energies of the plants are thrown into the pods that are already formed.

NAMES OF PLANTS AND FRUITS.

Names of plants.—A. S.—Limnanthes Douglasi.—M. B.—1, Limnanthes Douglasi; 2, Iris sibirica; 3, Phacelia tanacetifolia.—D. R.—Campanula glomerata dahurica; 2, Centaurea ragusina; 3, Cerastium tomentosum; 4, Veronica Andersoni.—A. S.—1, Diplacus glutinosus; 2, Astrantia major; 3, Oxalis floribunda; 4, Centranthus ruber.—H. D.—1, Tradescantia virginiana; 2, Geum coccineum; 3, Helianthemum vulgare var.; 4, Arenaria balearica.—W.—1, Malva moschata; 2, Nepeta Mussini; 3, Epilobium angustifolium; 4, Astrantia major.—G. J.—1, Sedum Sieboldi variegatum; 2, Lychnis Viscaria fl.-pl.; 3, Heuchera sanguinea; 4, Lycopodium formosa.—F. B. Harvey.—1, Hemerocallis flava; 2, Saxifraga granulata fl.-pl.; 3, Enothera Fraseri; 4, Polygonum Brunonis.—A. M.—1, Thalictrum flavum; 2, Lihertia formosa.—W. J. N.—1, Lychnis chalcedonica; 2, Boccia cordata; 3, Dictamnus Fraxinella albus; 4, Euphorbia Lathyris.—Frank Wynne.—Arabis petraea (a weed)—F. F., Leamington Spa.—Syringa Emodi.—D.—Probably Symphytum caucasicum. Should like to see better specimen.

City of London Rose Society.—We have been asked to state that, owing to the exceptionally cold weather we have been having, this annual show has been postponed to July 7th.

BIG SUMMER CLEARANCE.

200 BEDDING PLANTS.

12 varieties, packed separate, for continuous display, 2s.
12 EARLY CHRYSANTHEMUMS, 1-
 Strong plants, double and single varieties, some of the newest and best varieties. Carriage paid, 1s. 3d.

12 EARLY MORN TOMATO PLANTS, 1-
 Very finest and best for outside heavy crop.

300 AILSA CRAIG ONION PLANTS, 1-
 Just right for present planting; strong.

250 VEGETABLE PLANTS, 1-
 25 Onions, 6 Tomatoes, 50 Cauliflowers, 50 Cabbage, 50 Kale, 50 Sprouting Broccoli, 25 Lettuce, 1s.; with extra 25 Beet, 25 Beans, 3 Marrows, 3 Cucumbers, 300 plants, 1s. 6d.

LOVELY NAMED ANTIRRHINUMS

6d. dozen. Strong, bushy plants.
 Amber Queen, Vesuvius, Coral Pink, Pink Beauty, Carmine Queen, Yellow. Stock limited.

12 BEAUTIFUL ROCKERY PLANTS, 1-
 All grown in pots, turned out, and paped.

Achillea tomentosa, Sedum spuriun rubrum, S. Middendorffianum, Acena soribifolia, Linaria aquitri-loba, Iberis Little Gem, Saxifraga in six varieties, Aubrietia Richards, A. I., Huteubiana, alpina, Linaria pallida, Arenaria balearica, Thymus coccineus lanuginosus, Thymus carnosus, Veronica rupestris, V. Balfouriana, V. Bedwelli, V. silifolia, V. trebane. All strong flowering plants, 8 dozen, 7s. 6d.

W. H. CLARKE,
 29, Royal Hampton, Middlesex.

SWEET PEAS
A BLAZE OF BLOOM.

From their earliest days when only a few inches high to the time when they are a blaze of bloom, Carmona Sweet Peas are a triumph of growth—health, vigour, and beauty.

CARMONA PLANT FOOD

is recommended by most Seedsmen.

Scaled bags—14 lbs. 4/6, 28 lbs. 7/6, 56 lbs. 12/6,

112 lbs. 20/- Tins—6d., 1/-, 2/6

ROBINSON BROS., Ltd., WEST BROMWICH.

ADVERTISEMENT RATES.

Scale of Charges for Advertisements in "GARDENING ILLUSTRATED."

Line Advertisements.—Single insertions, 9s. per line, minimum three lines (about twenty words fill the first three lines, and nine words each additional line). Front page, if guaranteed, 1s. per line. No reduction for series.

Terms for Display Advertisements, 10s. per inch (reduction for series).

Advertisers not having a regular account at the office must accompany their orders with remittance. Orders and advertisement copy should be addressed—

MANAGER,

63, LINCOLN'S INN FIELDS, LONDON, W.C.

GARDENER WANTED for 2½ acres; in sole charge; fully competent to take charge of oil engine, electric plant with accumulators, and sewage with septic tank, and good knowledge small chicken farm with incubator and foster mother. Apply—Headlands, Berkhamsted, giving experience and salary required.

GARDENER.—Experienced person to take charge of hot-houses; single preferred. Cottage on premises. State age and salary required.—OAKES, Knockwood, Shortlands, Kent.

GENERAL SIR HORACE SMITH-DORRIEN requires a GARDENER (man or woman) who can harness and feed a pony; good wages; a boy kept. Address—Cell Farm, Old Windsor.

GARDENER'S WIDOW (38, no children) requires light position of trust where she can furnish two rooms. Salary required—Apply, Mrs. G., care of Mrs. WAUN, Broadham Green, near Oxted, Surrey.

A TRUE ECONOMY IN GARDENS.

A TRUE economy would be to stop altogether the clipping and distortion of trees and shrubs which are done to a vast extent in our gardens without the slightest reason, artistic or other. It is a wasteful expenditure of energy; injurious, too, in that it teaches young men that that sort of false form is right. As I go from the country to the "wen" I pass acres of disfigured Cherry Laurels sometimes shorn down without any reason except to get these trees to a dwarf state. If a shrub is wanted of that height why not plant the evergreen Barberry or other low-growing shrub, which would give one a free outline and natural grace without which everything worth having is lost?

But whatever it is, whether the Cherry Laurel, or the true Laurel, or the Yew, in our country seats there are these monuments of misdirected activities, sometimes miles of them, and imagine the thoughts of the men who are put to do this degrading work. Some places where men of scientific attainment are in charge are as much disfigured by this clipping as any others.

Look at the shrub garden against the Palm-house at Kew. It is disfigured with trees cut into the shape of billycock hats. The idea of wishing to break up the surfaces of gardens with shrubs taller than the flowers is right, but why not choose shrubs for this purpose that are of the right size to make distortion unnecessary? Many evergreens, from the true Laurel to the nobler Rhododendrons, have fine forms, which are easily destroyed by those who do not see true form. It is not unusual to see forest trees put under this indignity, but why plant a forest tree in the garden? The wood is the place for Yew, Beech, and Hornbeam, and these trees are wrongly placed in a garden, and can only torment the hapless gardener by spreading their roots where they should not be.

Another point of some importance is the loss of the beauty of form which trees and shrubs take in a high wind, and which is very striking in the Yew and the Cedar of Lebanon, and, indeed, almost any natural form of evergreen tree or shrub. One does not see this when such trees are cut into shapes and walls. Thus an enormous amount of labour is wasted. In one garden in Surrey I know there are several millions of Yews all cut down to the height of 6 inches or less, and this is done every year in order to carry into effect

some fantastic idea of an architectural gardener.

The hard lines of Yew hedges are most offensive to the artistic eye. Who can make a picture out of such deformities? And this distortion is not really an old English practice; much of it was brought on by Dutch William, and it then became the fashion to plant Yews to an inordinate extent in many gardens, such as Levens. The Yew is one of the hungriest of forest trees we have; it is impossible to grow flowers under it with any effect. If we look into the old Dutch books we find the whole idea of the Dutch gardener was to clip and shave everything into line, even forest trees were so trained into hideous examples.

Our most beautiful native trees are distorted in this way. Holly, Yew, Fir, and Box are trees which have their most beautiful form and colour in winter, and this is destroyed. Even the Ivy does not escape. I have lately seen a large and costly garden in which immense beds are almost entirely given over to an ugly variegated yellow form of the common Ivy. This has been planted with the misguided view of affording some colour in winter, but the result is indescribably hideous. In the same garden there are many variegated Yews cut to a shape. Many miles of Yew hedges have been planted of recent years by men who clearly did not know anything of the poisonous nature of the Yew and its fatal effects on horses and cattle.

Now we have another gift from the Dutch nurseries in the shape of Yews and Box clipped to many shapes—e.g., corkscrews, lambs, pheasants, and foxes. A garden with a stock of these must be well supplied with skilled labour to keep the abortions in "shape." Such labour might well be applied to the growth of beautiful flowers and shrubs. W. R.

NOTES OF THE WEEK.

The Silvery Geranium (*Geranium argenteum*).—After many years' acquaintance with this plant I doubted its health and good effect as a garden plant until I saw it at Friar Park—a silvery cloud of it happy between two bold rocks. It was a pleasure to see it after so many failures, including my own. It grew on the cool side of the rock garden, the raised position keeping it dry. Among the Cranesbills there are various good border and rock plants, this being a gem of the alpine species.—W.

Nierembergia rivularis.—It is curious to read the experience of one of your correspondents as to growing this in a shady and damp position. I have grown it here for years, and without success, in just such a situation, misled by the name *rivularis*. Now I succeed splendidly by growing it near large stones, in a distinctly dry position, and in hot sun.—RICH. H. BEAMISH.

Iris sibirica does well in a shallow tank sunk in the ground and filled up with ordinary loam. No drainage seems to be necessary for this or other marsh-loving Irises, and the stagnant conditions appear to suit them. They are a mass of bloom now and look lovely, the large pure white form known as *orientalis* Snow Queen setting off the blue and purple forms. I find many marsh plants will grow and flourish under similar conditions without any of the drainage which seems so necessary for some of the moisture-loving species.—W. O.

The Lettenhall Rose.—Under this name Sir Herbert Maxwell kindly gave me a charming single Rose some years ago. It is an early bloomer, and flowered in May with me this season. The large blooms are of good substance, and may be described as of a warm, deep pink. The habit of this Rose is erect, and it appears to be a form of *Rosa alpina*. It resembles one which I saw at Barskimming, known there as "Pink Arches," and which seems to have more of a climbing habit. It is also early, but a little later than the Lettenhall Rose.—S. ARNOTT.

Rose Anemone in Kirkcudbright.—This, said to be a hybrid of *Rosa levigata* or *sinica*, does very well on walls in the garden of Mr. W. D. Robinsou-Douglas, Orchardton, Kirkcudbrightshire. Facing west or south-west it is again blooming freely this year and is exceedingly handsome. The flowers, almost as large as those of *Rosa macrantha*, resemble in colour those of the H.T. La Fraicheur, and are described pretty accurately as "silvery-pink, shaded rose." At Orchardton, close to the sea, *R. Anemone* growing on a wall blooms freely. It is not generally known that this Rose is excellent for cutting and lasts well.—S. A.

Bamboos.—With reference to E. Markham's interesting notes on Bamboos in your issue of June 24th it would be very interesting to know whether he or any of your readers has made a success of *Phyllostachys Henonis* for any length of time. It

has had two trials in this garden, and each time after about three years, when just getting into its greatest beauty, it has flowered and died. It certainly is one of the most beautiful of the Bamboos to be grown in this country, but, of course, if this habit is general it does away with its value. *Arundinaria palmata*, I should say, is a most valuable covert plant, besides being one of the handsomest of them all when planted in a bold group, and with canes quite 9 feet long here.—M. F. YORKE, *Hillbrook Place, Iwer Heath, Bucks.*

Gentiana verna in Grass.—I see someone talking of this in GARDENING ILLUSTRATED. It is impossible in our coarse Grass. A little bit of thin Grass on a mountain would be different. I think I passed many acres of it in bare, peaty soil without a bit of Grass. In our rich English Grasses it would not have a chance. The Willow Gentian, being a woody plant, and accustomed to grow in rank Grass, would, I think, succeed.—W.

Senecio Grayi.—The handsome shrubby *Senecio Grayi* is not quite hardy in all districts, but in some where it is cut to the ground it makes good growth and flowers well the following summer. At Orchardton, Castle Douglas, Mr. W. D. Robinson-Douglas's delightful garden close to the Solway, it is occasionally cut down, but this season, after a similar ordeal, it has been flowering with the greatest freedom. In the rock garden the other day a good-sized plant was almost covered with the yellow flowers. So freely, indeed, were they produced that but little of the grey foliage could be seen. Readers who find this *Senecio* badly injured in winter will be well advised to cut it back and give it a chance of recovery.—S. ARNOTT.

Onosma tauricum is looking very pretty now with its numerous pendent heads of quaint, tubular, almond-scented flowers of a deep yellow colour, hanging over a rock ledge. It is very impatient of winter wet, and my plants all suffered more or less from the excessive rain which we had last winter; indeed, one or two of them died. Those which did come through, however, are blossoming very freely, although the centres of the clumps are looking brown and I fear that another wet winter may finish them off altogether unless they are protected with a pane of glass. I do not like plants which have to be coddled in this way, but with such wet winters as we have had recently some protection is necessary for species such as this if the plants are to be saved.—N. L.

Primula helodoxa.—May we correct the misapprehension that may be caused by "C. R.'s" note in your issue of June 10th. The flower-spikes of this new Chinese *Primula*, for which we secured the Award of Merit at Chelsea Show, measured from 29 inches to 36 inches high (we do not see "the ordinary Maidenhair Fern" that height in the East), and instead of the flowers being in "whorls of three," whorls of twelve flowers are common, and we have counted seventeen in one whorl. These plants were pot grown, others are over 3 feet, and they will no doubt easily exceed this in the open. As quickly as a stock can be raised there is no doubt that *Primula helodoxa* will become equally common and more appreciated than *P. japonica* and *P. pulverulenta*. Mr. J. C. Williams wrote us a week or two back: "I put five small plants of *P. helodoxa* into the narrow Rose-bed, opposite the front door, last autumn. They now have thirty-seven separate spikes, the best of which is 40 inches high, and plenty of them 25 inches to 36 inches." "C. R.'s" Chelsea friend may perhaps be referring to *P. serratifolia* or a yellow

form of *P. Cockburniana*, both of which are new and grow only about 1 foot high, with two or three smallish whorls. These were staged alongside *P. helodoxa* in the group among Maidenhair.—R. WALLACE & Co.

Eupatorium Raffii.—When I saw this *Eupatorium* (which is figured on page 321 of GARDENING ILLUSTRATED) in flower at Kew I took it to be an old plant with a new name. As far as my memory serves me it appears to be much the same, if not actually identical, with that grown at Kew forty years ago under the name of *Hebeclinium atrorubens*. That and *H. ianthinum*, both of which were afterwards changed to *Eupatorium*, used to be employed for the decoration of the greenhouse. According to the Dictionary of Gardening *Eupatorium atrorubens* and *E. ianthinum* are both natives of Mexico, the latter having been introduced in 1849 and *E. atrorubens* in 1862. As *E. atrorubens* is named in the Kew Hand List of Tender Dicotyledons one is scarcely prepared to learn that it has been overlooked, and it may be that the two are distinct, though, as above stated, I have my doubts.—K. R. W.

The deadly Yew.—I must write to tell you of our sad experience of the fatal effects of Yew clippings. About the beginning of the year some Yew trees had to be cut, and some (not a large quantity) of the clippings were thrown on a rubbish heap in what we call the park. No one seems to have known the danger. A few weeks after, our tenant turned seven bullocks into the park, and four of the seven died. We have had to pay compensation for the act of our servant. The man did not know, and even a nursery gardener whom I had to see in connection with the matter was ignorant of the danger. You cannot emphasise too strongly the necessity of keeping Yew, alive or dead, out of the reach of stock and of horses, which I am told are even more easily killed. Sheep seem either not to touch it or to be immune.—A. F. KIRKPATRICK, *Deanery, Ely.*

[It is surprising that the deadly properties of the Yew are so little known, even to gardeners. They ought to be taught to every child. Designers of gardens are careless in scattering Yew hedges about the country house when there are so many other plants that would make good dividing lines.—ED.]

— Under the heading "The Poisonous Principle of the Yew," I have the following note made in August, 1892. Lieutenant F. J. M. Stuart Wortley, R.N., Agricultural College, Downton, Salisbury, in a letter to *The Times* says:—

"I believe the actual poisonous principle of the Yew has never yet been definitely determined. Some weeks ago Mr. E. P. Squarrey told me he was of opinion that the male Yew was poisonous, but the female harmless to cattle. . . . Professor Munro is of opinion that if the poison in the Yew is taxine, the experiments (made by Mr. Stuart Wortley) go to show that Mr. Squarrey's idea is correct. . . . It is plain that taxine, whether or not it is the poison affecting cattle, is contained chiefly or entirely in the male Yew, and that if that is the poison, the female Yew may safely be planted in parks and pastures where cattle are turned out."

This may be of interest, and explain undoubted facts on both sides of opinion as to the Yew and its poisonous qualities.—M. W., *Haywards Heath.*

FRUIT.

GOOSEBERRIES.

THE excellent recipes in a recent number of GARDENING ILLUSTRATED as to various methods of cooking Gooseberries are very opportune, the crop in the majority of cases being heavy. One is glad to know of different ways of utilising this wholesome fruit, coming in as it does before other small fruits are ready. It is advisable not to use sugar with an over lavish hand, especially when the fruit attains full size or the pleasant piquant flavour is destroyed, or at any rate not so perceptible. The Gooseberry being so easily grown from the cutting onward, if a little care and intelligence are employed, it is a pity to come into contact, as one often does, with trees crowded with useless wood and suckers, and occupying a lot of space that might be more profitably filled. Nor is the sucker nuisance a speciality of home-grown trees. I have seen more than one collection of cordons with stems throwing up suckers in great profusion. When one realises the little trouble necessary to secure clean-stemmed trees it is a pity so little care is taken.

The heavy crop of fruit will steady the growth of bushes, but on the closely-pruned cordons there will doubtless be the same exuberance, and the summer pinching may be taken in hand as time permits. As with bushes, there is often the tendency in cordon cultivation to have a superfluity of wood, this in the case of the latter being the result of leaving too many spurs on the uprights, a perfect thicket of shoots following as soon as summer growth commences. A lot of these have to be broken out and just one or two left on each spur to form the material for another season's crop. The fruit on the cordon, being easily netted, is generally left for dessert, and after pruning, and before netting, it is well to give the trees a good dousing with the garden engine to free them of red-spider and keep the foliage clean for the remainder of the season. Where ripe Gooseberries are appreciated it is just as well to have a stretch of the dessert kinds as cordons, and a sufficient number of bush trees to meet the demands of the kitchen.

It is advisable to be careful in the selection of the sorts for cordons, those of a fairly erect habit of growth being preferable to others of a more pendulous nature, also to have them varied so far as the time of ripening is concerned, and in connection with the later kinds those that hang fairly well after attaining that stage. The best results are obtained in this direction if the foliage is kept in a sound, healthy condition. We have not been troubled much with red-spider this season, an absence of sun and occasional heavy showers checking its development.

Hardwick.

E. B. S.

Pruning Apple-tree.—Some Cox's Orange Apple-trees, planted here in late spring, were scarcely cut back at all. Should they not have been cut back three-quarters of the length of the shoots to encourage spurs? What would be the best method of pruning them in winter? Will it do to cut back last year's growth?—B. D. J.

[All things considered, the best way of dealing with the Apple trees in question would be to cut the last year's young wood back, as you suggest, to one-third of its length, or approximately so. They will, or should, then grow away vigorously next season. As the planting was done late little or no pruning was required, but in all such cases it should not be omitted the following autumn, and performed directly the trees begin to shed their leaves.]

PLANTS AND FLOWERS.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

RAMONDIA.

LATELY, at Friar Park, I was pleased to see a handsome plant of *Ramondia pyrenaica* growing among rock shrubs, showing itself with fine effect. Although the place is quite different from what is believed to be the best for the plants, its growth is charming to see, showing the extended use of this handsome plant.

W.

past week, it has been in profuse bloom. Very large pieces on the broad tops of the walls are particularly handsome. Occasionally sports are found, varying in colour from the type, and white-flowered plants are, while not numerous, at times met with. *Centranthus ruber* does well in cracks in the walls, one of the finest pieces being on a west wall partly overhung by a large Chestnut-tree, in which rather shaded position it blooms freely. *Linaria Cymbalaria*, like the *Erinus* referred to, is especially numerous, so much so, in some instances, as to be rather a nuisance, owing to its habit of invading the branches of fruit-trees. It might be inferred that,

with the masses of flowers it is now bearing when I saw it lately in the rock garden at St. John's College, Oxford. In our Sheffield garden we cannot grow it. Perhaps it is because the atmosphere has always a certain amount of sulphur in it. The plants, which reach a height of about 6 inches, and are covered with deep blue flowers, do best when planted between pieces of limestone.—E. T. ELLIS, *Bramcombe, Foxcombe Hill, near Oxford.*

Dianthus neglectus.—I think this is one of the loveliest of the alpine *Dianthi*, but there seem to be two different forms of it, one having much smaller flowers than the other. It appreciates a good soil in an open position, but not too hot, and, like most of the *Dianthi*, likes lime. It comes into bloom at the begin-

Ramondia pyrenaica in the rock garden at Friar Park.

WALL PLANTS.

ALTHOUGH no proper wall garden exists, nevertheless, at the present time the plants in the walls are noteworthy. These walls are much higher and more extensive than in more modern gardens, at places approximating to 20 feet in height. The walls are built of the local whinstone in irregularly-sized pieces, and beyond question the progenitors of the plants now growing in them were originally introduced into suitable crevices. In the course of years these plants have increased from seeds until, as has been indicated, the display of bloom during early summer is very striking. *Erinus alpinus* is present literally in thousands, and, during the

in such cases, there would be some danger of insect pests. Such is not the case, as close observation has shown. In the course of the week the walls in the neighbourhood of fruit-trees were examined, and such pieces of *Linaria* as were inclined to encroach were rooted out. There are also in the walls many Ferns, chiefly varieties of *Asplenium*, which, too, tend to become rather too numerous. At the same time, as has been said, they and the other plants referred to make the walls not the least interesting part of the garden just at present. KIRK.

Campanula muralis.—This lovely *Campanula* is now in full bloom. I was much struck with the freedom of its growth and

ning of June, and can be propagated by cuttings or by seed—the latter being the easier and better way, as the plants seem more vigorous than when grown from cuttings.—W. O. C.

Æthionema schistosum.—In this we have a good hardy plant, which has stood the last two winters in the moraine, and which I saw doing well also in another garden a few days ago. It is about 9 inches or 10 inches high, with narrow, glaucous foliage, and numerous heads of bluish-pink flowers. The central head is longer and more conical than the others surrounding it, these being flatter and bearing fewer individual blooms.—S. ARNOTT.

Campanula Raddeana.—This species does not seem so easy to manage as some. I had several plants in various parts of the rock

garden in well-drained soil, but the wet winter was too much for them, and they all died off except those which had been planted in the moraine, and which came through very well and are now just coming into flower. I find that many species which are supposed to require moraine treatment do quite well in a retaining wall, but *C. Raddeana* does not seem to be one of them.—NORTH LONDON.

Helichrysum bellidoides has been in blossom for some time, and is quite pretty with its little white, Daisy-like blossoms, though I think its value is somewhat over-rated. I grow it in the moraine, but it spreads very fast and in a small moraine is hardly worth the room it takes up. It seems quite hardy and is easily propagated by division.—W. O.

ORCHIDS.

GROWING CATTLEYAS.

PROBABLY no Orchids are more largely grown than Cattleyas, and if we include the other genera that readily cross with the various species we have a formidable

any repotting or top-dressing is when new roots are about to appear at the base of the new growth. Turn the plant carefully out of its pot and then remove all decayed compost, dead roots, and useless back pseudo-bulbs, as three behind each lead will be ample. These back pseudo-bulbs may be used for propagating if it is desired to increase the stock of any particular variety. Ordinary flower-pots are chosen, and these are filled to one-third of their depth with drainage, over which is placed a thin layer of rough fibre to secure a free outlet for water. The plant is then placed in position and the compost, which should consist principally of *Osmunda* fibre cut up into inch lengths, removing all the finer particles, worked well between the roots and brought up level with the rim of the pot. The surface is then neatly trimmed off. If thought desirable a few live heads of *Sphagnum* Moss may be incorporated with the last layer of soil. See that the plant

if unnoticed, the whole pseudo-bulb will be lost. Scrape away the decayed parts and apply lime, sulphur, or powdered charcoal until all the moisture is dried up. B.

CHRYSANTHEMUMS.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

BORDER CHRYSANTHEMUMS do not require much attention, but they well repay regular care. Many varieties of recent introduction are dwarf and do not need elaborate staking. As all must economise in labour, all the staking requisite may be done by fixing a few branching Pea-sticks round and among the growing stems in such a way as to ensure the natural habit of the plants. Use the Dutch hoe freely in fine weather, and water if the soil is dry. When the roots are permeating the soil freely a good soaking of liquid manure will be beneficial. Repeat the dose every ten days or so, and always when the soil is moist. Liquid manure may be made by putting one peck of manure into a coarse sack and immersing it in a tub of water containing about twelve gallons. Move the bag to and fro several times each day for three days, then use the clear liquid at the rate of one quart to a gallon of clear water. Fowl manure, also sheep manure, may, where obtainable, be used in a similar way. Do not disbud the plants, but encourage a natural growth, and thus secure a fine display of blossom on healthy foliage.

BUSH PLANTS FOR THE GREENHOUSE.—

These, grown in pots, will provide flowers for furnishing the greenhouse and for cutting after the outside plants are over. Here, again, a selection of neat Pea-sticks will prove useful, generally, one in the centre and three round the sides of the pots sufficing. The plants always grow very rapidly during September and October, so that the staking and feeding now must be judiciously done. For these and plants to bear larger blooms liquid manure should be used, as advised in the case of border varieties. Surface mulching will also be essential, and for this purpose use a good fibrous loam soaked for twelve hours in strong liquid manure and then partly dried on the floor of a cool shed before putting it on the soil in the pots. Thin layers, put on fortnightly, will prove most beneficial. In the case of plants to bear large blooms it will be necessary to pinch out all side shoots while they are quite small, only retaining the main stems and main leaves in readiness for bud-taking in August and the early part of September. Bamboo or similar stakes must be used for the due support of these plants.

PLANTS FOR LIFTING must not be neglected. They will grow more rapidly than those in pots and must not be unduly forced. Simply stake the plants temporarily against wind and keep the soil free from weeds. G. G. B.

Chrysanthemum Parson's White.—I think if this variety were called *White La Triomphante* no injustice would be done to the plant. The blooms are exactly those of *La Triomphante*, only white; and the foliage has the hereditary tendency of that variety towards mildew. It is equally free-flowering, a good doer, and, apart from its liability to mildew, quite a good early *Chrysanthemum* under any form of cultivation.—KIRK.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

Ramondia pyrenaica in the Royal Gardens, Kew. (See page 343.)

lot which produces some of the most gorgeous of blooms. The most suitable house is a span-roofed one with both top and bottom ventilators, and it must be fitted with ample piping. The temperature should average 60 degs. Fahr., but in winter it could fall to 55 degs., and in summer it may rise 10 degs. or 20 degs. and no harm will follow if due attention is paid to shade and ventilation. The ventilators should be opened whenever the elements are favourable, the object being to create sweet, buoyant conditions without producing a dry, arid atmosphere in which no Orchid will thrive. Shade will be necessary the greater part of the year when the sun is hot, and blinds must be so fixed that they can be run down when required. A moist atmosphere is essential, and the house should be damped down at least twice each day. The atmosphere may be allowed to become fairly dry for an hour or so during mid-day.

THE TIME TO REPOT.—The ideal time for

is quite secure, and until it is re-established the pseudo-bulbs may require some support.

WATERING is an important factor in Orchid culture, and is governed in its extent and frequency by the growth of the plant. Newly-potted examples require great care, and only enough should be given to keep the soil just moist. As root action increases, water may be afforded more liberally until the pseudo-bulbs are fully matured. At this stage only sufficient water will be needed to keep the pseudo-bulbs in a plump condition. Cattleyas do not appreciate a lot of spraying overhead, but if done with discretion and only on hot days they will derive a certain amount of benefit from the practice.

During the autumn and winter, Cattleyas of the labiata section should have their flower-sheaths examined periodically to ascertain if any moisture has accumulated at the base. This soon sets up decay, and,

OUTDOOR PLANTS.

LIFTING SPANISH IRISES.

THE question of lifting and resting Spanish Irises has interested me for a number of years. Going through the gardens of Mr. W. A. Coats, at Dalseairth, Kirkeudbrightshire, I observed some handsome clumps of a blue and white Spanish Iris in the best of health and flowering very freely. These appeared to me to be established clumps, and, on asking the gardener, he informed me that they had been planted for a number of years and were never lifted and replanted. In many gardens the Spanish Iris (*I. Xiphium*) appears to become weakened by being left too long in the soil. A safe rule is to lift the bulbs when the foliage becomes weak, either from overcrowding or from the soil being ungenial. A good many years ago I saw a very fine exhibit of *I. Xiphium* from Messrs. Cocker, of Aberdeen, at a show in

soil. I believe that it is better to lift the bulbs as soon as the leaves become yellow and to replant them at once in fresh soil. I know a good many places where *Iris Xiphium* thrives for many years and forms great clumps, but the point is worth considering by those who have lost their Spanish Irises by leaving them alone.

S. ARNOTT.

SOLOMON'S SEAL IN ROUGH, GRASSY PLACES.

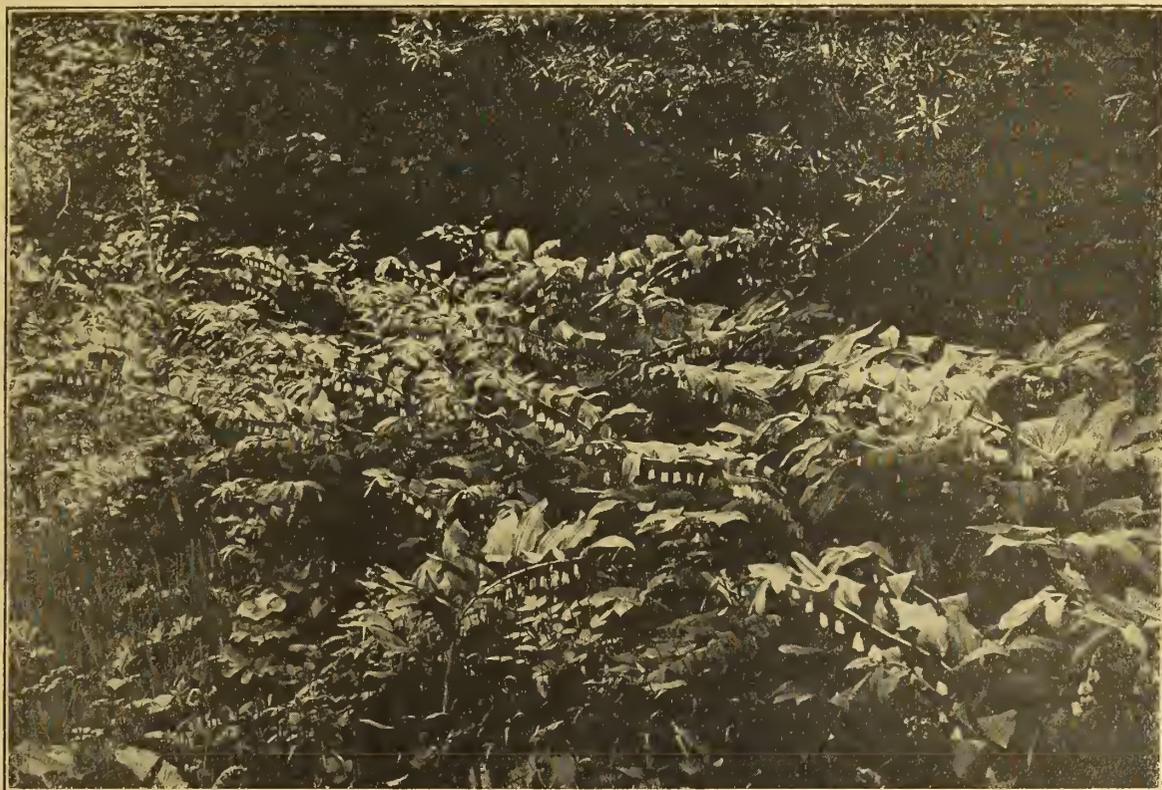

I HAVE seen many gardens in which no thought was ever given to such a plant as Solomon's Seal. It will not fit into flowerbeds, and should not, because the flowering is not long enough to justify its place in the flower garden. In places of any size there are often spots on the fringes of copse, shrubbery, or plantation in which this most graceful plant may be well grown. The colony figured has been growing for some years along a very little, rough bank, beside a streamlet in a spot

give a second crop of bloom, which, though, of course, considerably inferior to the first, will yet furnish a good display. Delphiniums, if they are not moved, do not exhaust themselves so readily as some herbaceous subjects. In proof of this I have some clumps which have been in the same place for five years continuing to increase in size and flowering well every year.—W. T.

PERENNIALS FOR HEAVY SOIL.

KINDLY give me a list of perennials that will do well on heavy clay? It is Wiltshire clay, and grows splendid Grass.—H. T. SHAWCROSS.

[It is only possible to give an approximately correct list of plants in such cases, experience of the peculiarities of local soils being necessary. There is, for example, a great difference between heavy soils that are constantly cool and moist and rarely contract, and those which, while heavy, contract badly in dry weather. Generally, however, you may

Solomon's Seal naturalised in old quarry.

Edinburgh. On discussing the point with Mr. Cocker I was informed that the flowers were produced by bulbs which had been three or four years in the ground without disturbance. "The English Flower Garden" is very emphatic on the question, and informs us that "The golden rule of not meddling over-much applies to the Spanish Iris." . . . "Plant the Spanish Iris in clumps on some rich, loose, friable plot where their bright colours may be shown to advantage, and let them stay there year after year until the dwindling foliage tells you that they have exhausted the soil." Mr. W. Rickatson Dykes tells us that "It delights in a warm, rich soil, and the bulbs should be lifted occasionally when the foliage withers, and separated before overcrowding occurs to diminish the size of the flowers."

In certain gardens known to me, where the soil is dry and poor, frequent lifting seems necessary, but the early growth from the bulbs appears to render it undesirable to keep them too long out of the

never mown, and where the plants can show their graceful bloom in May and fine colour in autumn without any care whatever. There are said to be some giant forms of this plant, but I have never been sure of getting them; the one we have is quite fine in form. W.

Delphiniums from seeds.—There is now quite a long list of named varieties of Delphinium, but where it is desired to have a good display at a cheap rate, seed saved from a good collection will yield a fine and variable lot of flowers. While the bulk of the flowers may not be the equal of those of the named kinds, they nevertheless make a grand display. Most seedlings, too, are characterised by a robust constitution, which is not always the case with those increased by division. From seeds I have obtained a great many delightful forms, varying considerably in colour. If the flower-stems of Delphiniums are cut off as soon as the blossoms are over many of the plants will

plant *Kniphofias*, *Acanthuses*, *Achillea Eupatorium*, *Anchusa italica* and varieties, *Michaelmas Daisies* in great variety, *Day Lilies (Hemerocallis)*, *Rudbeckias*, *Phloxes* if summer moisture is assured; such *Campanulas* as *grandis*, *carpatica* in variety, *latifolia* of sorts, the many good forms of *C. persicifolia*, *Heleniums*, *Erigeron speciosus*, *Monardas*, *Statice latifolia*, *Pæonies* in deeply-worked and rich soils, *Funkia*, *Lent Lilies*, *Lupinus polyphyllus*, *Everlasting Peas*, *Double White Rocket*, *Oriental Poppies*, *Eryngiums*, *Trollius*, *Veronica sub-sessilis*, *Doronicum*, *Lychnis chalcedonica*, *L. Viscaria rubra plena*, *Spiræa Aruncus*, *S. venusta*, *Pyrethrum uliginosum*, *Chrysanthemum leucanthemum* in variety, *Dictamnus Fraxinella*, *Galegas*, *Baptisia australis*, *Aconitum Wilsoni*, *Cimicifuga simplex*, *Astilbe Thunbergi*, *Thalictrum flavum*, *Spiræa filipendula*, and much besides. Had you stated for what particular purpose the plants were required we could have replied more definitely. Much

necessarily depends upon whether the plants are required for borders—narrow or wide—or for the rougher parts of the garden only. Much, too, depends upon the soil itself and how cultivated. Those given, however, are better suited to borders which, if well and generously cultivated, would grow many things well.]

NOTES AND REPLIES.

Growing Ranunculus.—Will you kindly answer the following queries:—1. When is the best time to plant Ranunculus bulbs—autumn or spring? 2. Also, best double kinds? My land is cold land, clay subsoil. 3. How deep to plant?—W. T. W., Gloucester.

[The situation should be open, but not exposed, and the soil a well-drained loam, to which has been added some well-decayed stable manure. About a month previous to planting, the bed should be prepared to a depth of 15 inches, and planting should take place about the last half of February; in some seasons it may take place in October, though such an early date is not the best. Drills about 5 inches apart and 1½ inches deep should be made with a small hoe; the claws of the roots should be placed downwards and pressed firmly into the soil, which should be raked over the roots, and a top dressing of about 2 inches of good loam given. If the surface soil is light it may be gently beaten with a spade in order to obtain a firm surface, and this may be repeated just before the foliage appears, say about a month or six weeks after the planting. As the Ranunculus delights in moist soil, water should be given if there is a scarcity of rain, and in no case should the roots be allowed to become dry. A light top-dressing of artificial manure or guano just as the foliage is above ground will do good. When the flowers are past and the leaves faded the roots must be taken up, dried, and stored in a cool place in sand till the next planting season, for roots left in the ground are injured by rains and never strong. It is useless to enumerate the different varieties, as they are usually sold according to colour, and are mentioned in nearly every bulb catalogue.]

Single Pyrethrums.—The new single Pyrethrum Pericles gives us another shade in these beautiful flowers, so that we now have them in crimson, pink, white, and yellow, besides intervening shades of a less distinct character. If not deemed advisable to purchase the best of the singles, an excellent selection can be obtained by sowing a packet of seed from a good strain any time early in spring. Prick off into prepared beds as soon as the seedlings can be handled, and let them remain there until they flower, so that the best can be selected for permanent planting. If not quite up to the form of the best-named varieties, these will make a good show and prove useful for cutting. Pyrethrums, being densely rooted and hungry plants, the ground for their reception should be well prepared, and if allowed to remain in the same quarters for several seasons, it may be found advisable to lift and replant annually. An association of these and Tufted Pansies makes a very effective bed.—E. B. S., Hardwick.

Calceolaria violacea.—This distinct and pretty Calceolaria is not much seen except in South of England and Irish gardens, where it often proves hardy. It is a quaintly pretty plant, with its helmet-shaped flowers of purple or violet, freely spotted, and always attracts attention. It needs shelter, however, in most places, and rarely stands the winter in the open north of the Tweed. At Culzean, the Marquis of Ailsa's garden, it is grown on a wall, and stands the winter.—A.

Dianthus Spencer Bickham.—This is a bright little hybrid Pink. It is only some 2 inches or 3 inches high, and forms a tuft of small, glaucous, spiny leaves. Above these rise, on short, erect stems, the bright-crimson flowers, which are effective, though so small. I find it thrives well on the moraine.—S. ARNOTT.

GARDEN FOOD.

THE HOME-GROWN APPLE SUPPLY.

JUDGING from the remarks of salesmen and from my own experience there would seem to have been a comparative slump as affecting the value and sale of home-grown Apples. It may be that fruit from the colonies arriving in a fresh state, and having such an attractive appearance, may to some extent account for the neglect of late keeping, British-grown fruit. We do not hear so much about growing late Apples now, possibly because it has been found a loss rather than gain to growers. Apples may be kept in suitable stores up to May and June if they have been purposely late gathered. If they are not carefully gathered, and the fruits left on the trees until the last moment, it is futile expecting good Apples even in March.

While the large growers at one time advocated the planting of late kinds, especially dessert fruits, there came a time when it was advisable to clear all stocks by the end of the year, because it was found once our markets were monopolised by the Colonial and American shipments then came a decline in the demand for home-grown Apples, though the imported fruits were dearer. I used to find a demand for good samples of such sorts as Reinette du Canada, Claygate Pearmain, Sturmer Pippin, Dutch Mignonne, Adam's Pearmain, and Bess Pool, but times have changed, and there is scarcely an inquiry for them at all now. This is my experience in the West of England, but whether such is the case in midland and northern markets I am unable to say. The tendency of our Apples is to become more or less shrivelled in the spring, and once this happens then their commercial as well as their edible value quickly depreciates. D'Arcy Spice has been referred to frequently of late as being among the very best of winter Apples. I have been the victim of mis-named trees. This has to be corrected by grafting or replanting, and thus time is lost. It is, I believe, not one of the showy kinds that find so much favour among purchasers, hence perhaps the reason why it has not become popular. Margil is another Apple of poor appearance, yet those who grow it set a distinct value upon it. Lord Burghley, where it succeeds, affords late dishes of plump, well-flavoured, crisp fruit. With me this cankered so badly it had to be discarded. King of Tomkins County, of American origin, generally keeps well, but, like the last named, is with me rather subject to canker, and the trees do not then remain long in a healthy bearing state.

The foregoing are all good Apples in a general sense, though soil influences are such that in some gardens some are unprofitable. It is in the market, not so much in the home provided with a good garden, where the influence of the imported fruit is felt.

W. STRUGNELL.

NOTES AND REPLIES.

Uses of Lettuce.—This vegetable, now so much grown, is too often, with us, thought of only as a salad. Welcome it is to all in that state, the more simply served the better. It should be borne in mind that its use in cooking is even more precious to us if we use it braised or otherwise prepared in the "conservative" ways now so often talked of and so often carried out in French cookery. It is often better in that way than any of the Brassica race in summer days. I was about to give recipes from a standard book on cookery, but drew back at sight of the needless things added to the dishes, nutmeg,

cayenne pepper, and salt, very doubtful aids to a good thing as a good gardener presents it. Adding such irritants to a dish is a British and a wrong way. French cooks use simpler means, and with good results. As the demand for salad may not lessen the stock, the cook should make good use of it in various ways. Here it should be said that the decoction called salad-dressing should be avoided. It must be bad Lettuce that would be made more palatable by it. For salad the best of all dressings are good olive oil and a squeeze of Lemon-juice, except for the epicure who prefers fresh Lettuce as it grows.—W.

Less Meat.—We quote from No. 4 pamphlet issued by the National War Savings Committee advice on this question:—"In ordinary times we get about half the meat which is consumed in this country from abroad. This is carried frozen in ships which have to be specially built for the purpose, and are, therefore, limited in number. Since the war began these ships have had to carry meat not only for our civil population and our own Army, but also for the French Army. It has, therefore, been a difficult task to keep up the foreign meat supply, and some shortage of this must be expected to continue. It is this shortage which has raised the price of meat, and may lead to our cows, which should be kept for milk, being killed for meat. This shortage of meat would disappear, the price of meat would fall, and our milk supply would no longer be threatened if everyone were to eat less meat than they have been accustomed to, especially during the summer and autumn months. Most people would not suffer in the least in health or strength by so doing, especially if they were to include in their diet a fair proportion of food which can supply the same kind of nourishment as meat."

A wholesome jam.—All those who wish to keep well should avoid artificial sugars in cookery, and take into the system only those contained in the fruits. This is quite practicable even for those wishing to preserve fruits for winter in the form of jam. I have experimented as follows on some fruit presented to me by one of my patients, with the result that all who tasted it considered it to far exceed the old-fashioned way. Here is the recipe:—To every pound of fruit allow ¾ lb. of Dates. First wash and drain your fresh fruit and throw into a clean enamelled saucepan; mash it down with a wooden spoon until you get some syrup, then throw in the Dates either stoned or not, after washing them in hot water; keep the fruit well stirred whilst cooking, and only allow it to simmer for about two hours; get the jars hot and dry, and pour in the preserves at boiling point; have ready some melted mutton suet or olive oil hot and pour over the top, tie down tightly at once and keep in a cool, dry place, and you can keep it any length of time.—MRS. MAY.

The high tea.—The typical North Country "high tea" will run through the whole gamut of cold meat or potted meat, Beetroot in vinegar, bread-and-butter, bannocks, scones, stewed fruit and sugar, milk pudding, cake, parkin, etc., all of which will be "washed down" with copious draughts of sugared tea. What is wrong with this meal? It has the fault of bringing together in unhappy digestive association the most unsuitable companions—sugar and vinegar, baking soda and potted meat, unripe fruit and soft starches, strong tea, and meat.—E. A. SAXON.

[With such coarse feeding, is it any wonder the Briton eventually blossoms out into a repulsive mass of gout or rheumatism?—Ed.]

INDOOR PLANTS.

ABELIAS.

THE Abelias form a small group of some five or six kinds, all mountain plants, and native of the hills of China and Japan, the uplands of India, and the mountain

Their pretty flowers are charming in drooping clusters, lasting long, and the good effect is continued after their fall by the coloured sepals, which retain their beauty far into the autumn. They may be increased by layers in spring, or by cuttings under a handlight during summer. Two Chinese forms known as

spot. The flowers, each about 1 inch long, are carried in clusters and are of a pale-blush colour, fragrant, and lasting for several weeks in early autumn. Even after the flowers drop the reddish sepals are still ornamental.

A. FLOREBUNDA.—This, which we figure to-day, is the finest of the group, but, save

Abelia floribunda in the greenhouse at Nymans.

in mild parts, must be grown under glass. Even in the south it is best as a wall shrub, when its evergreen leaves and drooping flowers are well seen. The flowers, coming in March and April as drooping clusters from every joint, are of a bright rose or rosy-purple, each about 2 inches long, and hang for many weeks upon the plant. It does best in light soil, and when grown in pots should be kept rather confined at the root. It is found in the mountains of Mexico up to a height of 10,000 feet.

A. SERRATA.—This species is found as a low evergreen bush upon dry and sunny hillsides in China and Japan. It is smaller in all its parts than the other Chinese species, growing little more than 3 feet high, with solitary pale-red flowers, which are large and sweet, appearing in March.

A. SPATHULATA.—This bears white flowers, marked with yellow in the tube, coming in pairs from every joint, and about 1 inch long. The leaves are rather long, finely toothed, with a pale-purplish edging.

A. TRIFLORA.—This is less hardy than the Chinese forms, needing the shelter of a wall. Being of robust growth it soon makes a fine object, of good habit, and branching freely. The flowers, coming in threes at the end of summer, are cream or pale-yellow flushed with pink, their beauty enhanced by the rosy colour of the unopened

buds. Grown in pots or tubs, it is a fine plant for the greenhouse, where it cannot be grown in the open.

Hydrangeas.—To have plants for forcing into flower early in the season the cuttings should be taken and struck in a propagating case now. An abundance of shoots of a suitable nature is now avail-

ridges of Mexico. Few of them are hardy in all parts of our country, though those that may be grown in the open air are beautiful and uncommon. In mild districts, with light soil, in sheltered corners on warm walls, they thrive in favoured parts. They do best and are hardiest in light, warm soils, enriched with peat or leaf-mould, and in well-drained spots.

rupestris and *uniflora* are not considered distinct at Kew, and are therefore united under the name of *A. chinensis*. The following kinds are in cultivation:—

A. CHINENSIS.—This is a pretty and distinct shrub, usually of dense growth, reaching a height of 3 feet to 5 feet. It is the hardiest kind grown, and to do well needs a warm, light soil and a sheltered

able on plants which have already been forced. They root quickly if taken and potted at once, singly, into small 60-pots filled with sandy compost, placing a little sand at the base of the cuttings and putting them at once into the case. With a good watering at the outset, but little will be required for some time afterwards, but the soil must, nevertheless, not be allowed to become dry. Shading from direct sunlight is necessary. Plants propagated in this way and shifted on afterwards into 5-inch and 6-inch pots throw up magnificent heads of flowers when forced the following winter.—A. W.

HELIOTROPE IN BAD HEALTH.

Will you kindly tell me with what the Heliotrope leaves sent herewith are affected, and the cure? It was badly infested with same thing last year. I pruned it back severely in the spring, and have several times fumigated with XL compound, which I find very successful with green-fly, but it does not seem to affect this white-fly. I also had the wall behind the Heliotrope limed in the spring, so am the more disappointed at the reappearance of this pest, as I do not know what else to try. Will you kindly tell me if fumigation is of any use in keeping Ferns free of scale and white-fly?—A READER.

[The white fly (Aleurodes), with which your Heliotrope is infested, is a difficult subject to get rid of. The fumes of hydrocyanic gas will destroy it as it will all other insect pests, but it is of too poisonous a nature to recommend. We have got rid of the white fly by persistently vaporising with the XL All vaporiser, in conjunction with spraying with paraffin emulsion or soft soap and quassia. A single vaporising is, however, of no use, as it destroys only the perfect insects, and even some of them drop to the ground and escape. Four or five vaporisings at intervals of about four days are necessary in order to effect a cure. Judging by the leaves sent, which are attacked by scale as well as by the white fly, we should say that your most satisfactory plan will be to do away with the Heliotrope and burn it, taking care to disturb the flies as little as possible before the plant is outside of the greenhouse. If this breeding place is not got rid of, the pest will spread to many other plants in the same structure. The plants most liable to attacks are those with leaves of a soft nature, which include, besides the Heliotrope, Abutilons, Fuchsias, and Bouvardias. Tomatoes, too, are very subject to its attacks. Fumigation, or rather vaporising, has little or no effect on scale, though it tends to check mealy bug. Once scale effects a lodgment on Ferns the badly-infested fronds should be cut off and burnt, and the others cleaned by hand.]

Unhealthy Gloxinias (P.).—The Gloxinias are, from specimens sent, simply eaten up with thrips, generally caused by too hot and dry an atmosphere surrounding them, just the condition under which yours were grown, as you say the house is a hot and dry one and has had but little moisture in it. No treatment will restore the plants to health now, as they are too far gone. Another season use more moisture in the house, and if any thrips are seen vaporise at once two or three nights in succession.

Chinese Primulas.—These are now at their best, and comparing the varieties now at the disposal of the grower with those of the late 90's and early years of the present century, the difference cannot fail to strike those who have watched the progress of the family. The stellata varieties grow more popular, while the rich range of colour in all classes makes the Chinese Primula indispensable in spring. The double forms, among which at one time there were some good things, are now rarely seen, with the exception of the useful Double White.—KIRKCOUBRIGHT.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM JULY 5TH.—*Ostrowskia magnifica*, *Eremurus Bungei*, *Tritomas*, *Delphinium nudicaule*, *Potentilla nitida*, *P. arbuscula*, *Dianthus* (in variety), *Gypsophila transylvanica*, *Hypericum* (in variety), *Achillea Huteri*, *Ononis fruticosa*, *Linarias*, *Saxifraga valdensis*, *S. Cotyledon pyramidalis*, *Tunica Saxifraga*, *Saponarias*, *Aubrietias*, *Viola bosniaca*, *V. lutea*, *V. cornuta*, *V. gracilis*, *V. Rothomagensis*, *Veronicas*, *Helianthemums* (many varieties), *Cistus* (in variety), *Thymus* (in variety), *Omphalodes cappadocica*, *Libertia formosa*, *Campanulas* (in great variety), *Pulmonarias*, *Valerians*, *Lupins*, *Thalictrums*, *Gysophilas*, *Sedums* (in variety), *Convolvulus althæoides*, *C. Cneorum*, *C. mauritanicus*, *Dryas octopetala*, *Gnaphalium trinerve*, *Heucheras* (in great variety), *Incarvillea Delavayi*, *Onosma albo-roseum*, *O. tauricum*, *Ourisia coccinea*, *Alpine Poppies*, *Ramondia pyrenaica*, *Cypripedium spectabile*, *Androsace lanuginosa*, *Astromerias*, *Lychnis Haageana*, *L. chalcadonica*, *Phlox subulata Vivid*, *P. s. The Bride*, *Lithospermum intermedium*, *L. petraeum*, *Galega Hartlandi*, *Eriogon speciosus*, *E. macranthus*, *Delphiniums* (in variety), *Achillea ptarmica* *The Pearl*, *Lilium croceum*, *L. candidum*, *L. Szovitzianum*, *L. Martagon*, *L. Hanson*, *East Lothian* and *Ten-week Stocks* (in many colours), *Carnations*, *Antirrhinums* (in many colours), *Gazania*, *Dianthus Heddebergi*, *Candytuft*, *Petunias*, *Salvia patens*, *Calceolaria amplexicaulis*, *C. mexicana*, *Heliotrope*, *Ageratum*, *Ivy* and *Scented-leaved Pelargoniums*, *Tufted Pansies* (in many varieties), *Pentstemons*, *English* and *Spanish Irises*, *Gladiolus The Bride*, *G. Peach-blossom*, *G. Ackermani*, *Sweet Peas*, *Clematis* (many varieties), *Colutea arborescens*, *Escallonia macrantha*, *E. Edinburgh*, *E. langleyensis*, *Viburnum Henryi*, *V. tomentosum Mariesi*, *V. plicatum*, *V. Opulus*, *Olearia Gunniana*, *Philadelphus* (in variety), *Weigelas* (in variety), *Stranvessia undulata*, *Daphniphyllum macro-podum*, *Tricuspidaria lanceolata*, *T. dependens*, *Schizophragma hydrangeoides* (Climbing *Hydrangea*), *Hydrangea hortensis*, *Abutilon vitifolium*, *Solanum crispum*, *Teucrium fruticosum*, *Carpenteria californica*, *Drimys Winteri*, *Per-nettyas*, *Cotoneasters*, *Raphiolepis ovata*, *Robinnias*, *Spiræa Douglasi*, *Fuchsias*, *Nymphæas*, *Carex paniculata*, *Ranunculus Lingua*, *Lysimachia vulgaris*, *Iris aurea*, *I. ochroleuca*, *I. Kamperfi*, *Rodgersia dodephylla*, *Primula sikkimensis*, *P. pulverulenta*, *P. Bulleyana*, *Senecio japonica*, *S. Greyi*, *Roses* (many species and varieties).

WORK OF THE WEEK.—The recent showery weather has been very suitable for transplanting seedlings. Wallflowers have been transplanted into rows 12 inches apart, allowing not less than 9 inches between the plants in the rows. If the sun is very powerful after they have been moved they are afforded a moderate amount of shade during the day, removing the covering at night so that the plants may receive the full benefit of the dew. Seeds of Canterbury Bells, Delphiniums, Potentillas, Foxgloves, and Pyrethrums have been sown on a south border, and the seedlings will be pricked out into nursery beds as soon as large enough to handle. Autumn and winter-flowering Cyclamens have been sown on a south border and the seedlings will be pricked out into nursery beds as soon as large enough to handle. Autumn and winter-flowering Cyclamens have been lifted and replanted where necessary. *C. europæum* and *C. neapolitanum* generally start flowering early in September, so there should be no delay in planting. *C. Coum* flowers during winter and early spring, and enjoys plenty of leaf-soil in a partially shaded position. Some choice varieties of Daffodils have also been lifted and replanted. Cuttings of *Æthionemas*, *Androsaces*, *Drabas*, *Linarias*, *Morieia hypogæa*, *Asteriscus maritimus*, *Ageratum oxylobus*, and *Saxifrages* have been put in during the week. Weigelas, as they pass out of flower, are given what pruning they require, this consisting in the removal of some of the older branches. Philadelphia will also be thinned out after flowering. Climbing Roses on arches and pergolas are throwing up strong basal growths which have been made secure to prevent their being

damaged by winds. Where more are springing up than will be required the surplus ones are removed early to strengthen those retained.

Northants.

F. W. GALLOP.

SOUTHERN COUNTIES.

Late Potatoes.—These now need to be cleaned, weeds being very abundant. This will be done with a scuffle, which is set so that it cuts just deep enough to get the weeds up by the roots. After these are cleared off, the scuffle is again used to work the soil between the rows and get it ready for moulding. Before this takes place a Potato manure applied according to directions is strewn between the rows. The moulding will be done by horse labour, a moulder being attached to the front of the scuffle for the purpose.

Early Potatoes.—These are lifting well, and as fast as the ground is cleared it is cropped with something which will turn in and leave it vacant for winter digging. The crop is very satisfactory in every respect, which, to say the least, is surprising when the weather experienced since planting took place is taken into consideration.

Celery planting.—The plants, with the exception of the latest, will be got out without further delay. Part will follow early Peas and part the earliest spring Cabbage. The trenches will be opened out wide enough for two rows of plants to be set out in each and manured at once.

Onions.—These are at last fit for thinning, and all gaps in the rows will, therefore, be made good. After this is done the soil will be well hoed and the plants encouraged to make quick growth and make up for lost time.

Carrots.—The plants from the second sowing of a maincrop variety are now ready for thinning to 6 inches apart, this, seeing the season is far advanced, being quite wide enough to leave them apart.

Sweet Peas.—Two long rows sown a few weeks ago have done remarkably well, the growth being very vigorous and healthy. Moulding and etaking of the same have been carried out, and good results in the shape of an abundant crop of flowers should follow.

Border Chrysanthemums.—Encouraged by recent rains, very satisfactory growth is being made. To further stimulate growth, a dressing of Chrysanthemum manure will now be applied, which will be mixed with the soil by well hoeing the surface with a draw hoe. Staking will soon require attention. This is best done before the growths become bent or fall over and the symmetry of the plants spoiled. Bamboo canes are more suitable for this purpose than anything else, as they are, if judiciously disposed and used as sparingly as possible, less obtrusive than ordinary stakes. Frequent hoeing of the surface lessens the need for watering, but at the same time the plants must not be allowed to flag.

Border Carnations.—These have been staked and tied, and the hoe run through afterwards to loosen the surface. In dry weather these need to be plentifully supplied with water.

Cinerarias.—The seedlings should now be put into small-sized pots and be grown in the cool atmosphere of a frame stood over a bed of ashes and facing north. Vaporise should green-fly put in an appearance, and should an attack be set up by the leaf-miner, which in some seasons is very troublesome, pick off and burn the infested leaves directly it is noticed. This is often the means of preventing any appreciable amount of damage being done. Young plants resulting from the second or last sowing should be pricked off either into pans or boxes, and as soon as large enough shifted into small 60-sized pots.

Primulas.—These need much the same treatment as the foregoing, both in regard to potting on and in giving them frame culture, only the frame is best kept rather closer than is advisable for Cinerarias.

Herbaceous Calceolarias.—The seed should now be sown if the plants are required to bloom in May next. Pans are the best in which to sow. They should be filled to within half an inch of the rims with fine, light, rich, sandy compost. This should be made quite firm and then thoroughly watered. After

draining for an hour, sow the seed and scatter a very small quantity of silver sand over it. Cover the pans with glass and keep shaded with paper or Moss until germination takes place, when it must be removed and the pans stood close up to the light to prevent the plants becoming drawn. A careful watch for slugs, etc., must be kept or many of the plants may disappear in the course of a night. It is a good plan to place the pans on inverted pots, which, in turn, should be stood in earthenware saucers kept filled with water. The seed may be raised either in gentle warmth or in a frame, one being as good a way as the other, the only difference being that the seed is longer in coming up in the frame. Afterwards cool-frame culture should be accorded the plants for some time to come.

Cyclamens.—The corms raised from seed sown in the autumn of 1914, having experienced a thorough rest, are now starting to grow anew. This is the best time to shake out and repot them. Care is necessary in doing this, as oftentimes great injury results through the corms being too severely denuded of the old roots. The pots should be clean and well drained, the compost consisting of good fibrous loam, leaf-mould, a little lime rubbish, some dried cow-manure rubbed through a fine sieve, and a liberal quantity of coarse silver sand. In potting keep the base of the corms just beneath the surface of the soil, make the latter fairly firm, and dredge a little sand over the surface afterwards. Place the plants in a frame or pit, which keep close and shaded for a time or until new roots are emitted and fresh leaves appear. Until they recover from being shaken out, it is a good plan to syringe the corms in fine weather two or three times a day.

Wallflowers.—The plants raised from seed sown last month require to be pricked out in lines 1 foot apart, with a distance of 9 inches between the plants. Cut off the tap-roots, as this ensures the plants becoming much better rooted than if left on. In addition to this, they also then lift with a good ball of soil attached to the roots. The soil should be firm and not too rich, as the firmer and more sturdy the growth the more likely are they to pass through the winter unscathed.

Sweet Williams.—Seed should now be sown to provide plants for setting out in autumn for blooming next June. A good-sized box will furnish an ample supply of plants for all ordinary purposes. A. W.

MIDLAND COUNTIES.

Strawberries need sunshine to ripen the fruits. As I write, the fruits have not been dry for several days, although very little rain has fallen. Slugs have increased to an alarming extent, and are spoiling many fine fruits even before they change colour. The late varieties look exceedingly well, and, as the weather is damp and cool, they are backward, many being only in bloom. Laxton's Latest, Givon's Late Prolific, and Latest of All are three reliable varieties for late fruiting in this locality.

Raspberries promise a bountiful crop. All suckers not required for next year's fruiting have been removed, and a soaking of liquid manure given.

The Loganberry.—The strong basal growths of the current season have been reduced to five or six of the more robust, and these secured to the wires, so that they do not become broken or twisted at their bases. The Loganberry resembles the Raspberry in that it requires plenty of feeding during the summer.

Apples are a very light crop in this locality, and many trees have not a single fruit on them. Pears appear to be a good average crop, and thinning of the fruits is necessary on many trees. Large trees which have filled their allotted space are kept closely pinched, whilst young trees, having further space to furnish, are allowed to extend. Even young trees require extra strong shoots to be stopped in order to preserve a proper balance of the tree. Continue to stop and thin the shoots on all fruit-trees as recommended in previous notes, especially all side and lateral growths not required for extending the tree.

Melons.—Plants swelling their fruits are afforded plenty of stimulants, liquid cow-manure being an excellent stimulant. Where fruit is ripening manure is withheld and clear water given only moderately. As soon as the fruits are cut another batch of plants will be placed in the same pit for fruiting in September. The young plants are in readiness and well rooted in 5-inch pots. All the soil from the old bed is removed and the house thoroughly cleaned with soft soap and water. The borders are made very firm, with new soil placed in the form of a ridge. The Melons are planted 18 inches apart on the ridge, staked and tied, and when all is finished a good watering with tepid water is given. The atmosphere of the house is kept close and damp, and the plants sprayed overhead both morning and evening. When the plants begin to grow freely more air is admitted in suitable weather.

Liliums.—As the various batches of these plants come into bloom they are removed from the house in which they have been gently forced to a cool and shady house, where the blooms last in good condition much longer than in a close and warm atmosphere. *L. speciosum rubrum* and *L. s. album*, for autumn flowering, are placed out-of-doors in a shady position, and are frequently fed with good liquid-manure, never letting the roots suffer from the want of water. Occasional sprays with Quassia extract keep them free from aphid.

Autumn-sown Onions which have not yet commenced ripening to the top growth should be broken down at once preparatory to their being harvested. As soon as the bulbs have attained to a fair size, and before any signs of splitting can be observed, they should be lifted carefully and well dried before putting them under cover. It is generally complained that these Onions will not keep well, but this is frequently because the bulbs are allowed to remain too long on the land before lifting.

Celery.—The earliest plantings are now growing away freely. Each plant should be carefully examined and all side growths and split leaves removed. Keep the soil constantly stirred on the surface, and give frequent small doses of artificial manure and soot. Damp overhead twice daily in fine weather and water freely at the roots. If not already done, no time must be lost in completing the planting of the latest sown plants. It is a good plan to arrange for the trenches to be got out between the lines of early Peas, the latter affording just sufficient shade to enable the Celery plants to get over their removal quickly. I prefer to plant double lines at this season. Lift the plants with good balls, shorten back the longest leaves if at all drawn, and plant very firmly.

Peas are very late this season. Owing to the absence of sun the pods do not fill, but there is every promise of an abundance later on. The latest sowings have been well thinned and securely staked.

Broad Beans.—Late sowings of these have to be kept well syringed with insecticide to keep them free from black aphid. Strong soft soap and water answers well and is both safe and effectual. Stop the growths in good time, mulch between the rows, and water freely in dry weather.

Coleworts.—Another good sowing of both Rosette Colewort and London Hardy Green will be made at once. These will stand the winter much better than the early sowings, and give useful supplies during early spring, when Cabbage is often very scarce. Continue to take every opportunity of showery weather to plant all kinds of green vegetables for winter use, filling every available piece of vacant ground. F. W. GALLOP.

SCOTLAND.

Hardy-flower borders.—From now onward a full display may be expected from hardy plants. Very vivid are the Oriental Poppies, although their display is a trifle fleeting. After flowering, the bed in which these are grown assumes rather an untidy appearance; but I think it is better to tolerate this than, as I see practised sometimes, cut over the foliage. This induces a second growth which may bloom in late autumn, but the extra

strain upon the plants must in time lead to deterioration. Many Irises are in bloom. Pyrethrums (single and double) are at their best, *Thalictrum aquilegifolium album* and the variety *atropurpureum* are very free, while the Day Lily (*Emerocallis flava*) is in full flower. This is one of the few hardy plants which seems to increase in effectiveness year by year when left undisturbed. Just on the point of expanding, *Morina longifolia* will presently add its pinkish-white whorls to the number of hardy plants in bloom. Sea Hollies, as usual, are strong and vigorous, *Eryngium planum*, *E. amethystinum*, and *E. Zabelli* being already in flower. Colonies of Lothian Stocks in a south border yet remain effective, and towards evening their perfume is especially noticeable. If rather coarse, *Senecio sarracenus*, in a heavy, rather shaded border, is not unworthy of a place among the taller and more robust herbaceous plants, such as *Epilobiums*, *Rudbeckias*, *Napæa dioica*, *Funkias*, *Eupatoriums*, and the like. During the week some further hoeing, tying, etc., were attended to, and as a tankful of liquid-manure was available a good drenching was given to large clumps of *Kniphophias*. These respond well to occasional applications of liquid-manure given fairly strong. At the same time, an allowance was afforded to *Delphiniums* now beginning to show colour.

Wallflowers.—In the course of the week seedling Wallflowers were dealt with, some going into nursery beds in the open, and some hundreds being put into a bed in a two-sash cold-frame. There will, of course, owing to the restrictions, be very many less bulbs available for spring work, so that it is advisable to prick off a larger quantity than usual of Wallflowers.

Cucumbers.—A final planting was made in a pit upon a partly expended hotbed. These plants will now come away rapidly with the sun-heat alone, and if shut up early in the afternoon and kept in a rather moist atmosphere they will provide good supplies throughout the autumn, or, at least, until the pit is again required. Previous plantings are turning out well and will maintain the supply for an extended period. Rich top-dressings are very necessary to keep up the vigour of Cucumbers, more especially during the early stages of bearing. If a few inches of mellow loam are added to the top of the bed every ten days the roots will speedily take possession of it. If it can be spared, a little good artificial manure may, with advantage, be mixed with the loam previous to top-dressing. Equally important is the regular pinching of the young shoots. One leaf beyond the fruit is sufficient; any more will lead to overcrowding and a cessation of fruiting. In the case both of Cucumbers and of Melons we cannot, during the present summer, work, as formerly, by the clock. In this district, generally speaking, the usual hour for closing Cucumber and Melon pits in sunny weather used to be 4 p.m.; now, of course, shutting is deferred until 5 p.m., when syringing is done. In any case, however, on exceptionally sunny days it is much more advisable to follow the sun than to have a hard and fast hour for shutting up.

Late Potatoes.—In the course of the week the cleaning of late Potatoes was finished, and immediately afterwards they were moulded up with the plough. So far these Potatoes are very promising, more especially King Edward VII., a variety which is always an outstanding success in these gardens.

Turnip-thinning was attended to as became needful, and further lines were sown. The latter included Six-weeks, White Stone, and Orange Jelly. A breadth of Swedes was thinned finally to a distance of 10 inches from plant to plant.

Brassicac.—Further breadths of Brassicas were got out. These included Early Ulm Savoy, Drumhead Savoy, Eclipse and Autumn Giant Cauliflowers, and Curly Kale. Blanks—not very numerous—in previous plantings were, at the same time, made good.

Celery.—Another trench was filled with Celery during the week. So far, the weather has been suitable for this important crop, and as planting was, in all cases, accomplished under the most favourable conditions, no watering home has been needed.

Fruit-trees in pots.—When the fruits are swelling freely rich top-dressings and plenty of moisture are indispensable, but when ripening begins less water is necessary. Most fruits, especially Peaches and Nectarines, are easily spoiled when a too free use is made of water when they are finishing. If the pots have been, as previously recommended, partially plunged, when less water is given the roots will push out through the holes in the bottoms of the pots, and in this way obtain what support and moisture they require. As regards watering at the present time, do not permit it to be done indiscriminately. Every pot ought to be individually tested daily, and when found to require moisture let the soil be thoroughly soaked. The syringe may yet be kept regularly at work twice a day, and if black aphid appears no time should be permitted to elapse until it is effectually dealt with. Tobacco powder is as good for exterminating this pest as any other specific.

Balmoe Gardens, Kirkcudbright.

NATIONAL ROSE SOCIETY.

JUNE 30TH, 1916.

THE exhibition of this Society was held on the above-named date in the Royal Botanic Gardens, Regent's Park, and probably no flower festival is looked forward to with greater interest or receives a larger measure of support. This year, however, owing to a variety of causes beyond the Society's control—difficulties of transit and shortage of labour chiefly—the show was shorn of its usual fulness, the blooms also having suffered appreciably in size, colour, and quality, owing to the exceptional cold and sunlessness of the weeks immediately preceding the show. From these latter causes alone it would appear that the show at the end of June was, this year at least, a little too early for the Rose. This year the group classes were less well filled, and a greater proportion of table spaces than we before remember were vacant. Some growers of note, who in former years had staged well, said they "were quite unable to show." What we missed most of all was the superb splendour of the "Silver Medal" Roses. Hence, as we have already hinted, the date this year—so great a factor is the weather in this connection—was too early for the flower. These things notwithstanding, there was still presented to view a great exhibition, an exhibition which in its hundred odd classes caters for all phases of Rose growing as well as utilitarian display. If we might venture a couple of hints they are, first to the executive to arrange the exhibits—those of the table classes particularly—in the consecutive order of the schedule, and to exhibitors of blooms in boxes that the names be not so cleverly hidden from view. Queen Alexandra was an early visitor to the show, and, while displaying the keenest interest in the flowers generally, selected from the stand of Messrs. Alex. Dickson and Sons, Newtonards, two magnificent baskets of blooms—the golden Margaret Dickson Hamil and the scarlet Donald McDonald.

Following are some particulars of the show, exigencies of space precluding our giving a complete report.

NURSERYMEN'S CLASSES.

Seventy-two blooms, distinct varieties (champion class), for which the first prize is a trophy, gold medal, and £7 in cash, brought five collections, the premier award going to Messrs. A. Dickson and Sons, Newtonards, Ireland, who showed, among others, the rich yellow Mrs. Stuart Clark, Mme. Melaine Souperet, Avoca (fine red-dish-scarlet), Red Cross (fiery-crimson, very telling colour), S. J. L. Mock (pink), and Lady Greenall (cream with golden

base, very handsome and distinct). Messrs. D. Prior and Sons, Colchester, were a good second, their blooms of Medea (soft yellow), H. V. Machin (brilliant scarlet), Mildred Grant (a highly popular variety), Mme. Jules Gravereaux, and Mrs. C. Reid (blush) being of outstanding quality. In the class for forty distinct varieties, three of each, four collections were staged, the two exhibitors above named occupying similar positions. Here, again, Red Cross, a glorious crimson and more conspicuous than in the preceding class, caught the eye at once; not less so the superb quality of the new golden-yellow Margaret Dickson Hamil, for which no description could give an adequate idea of its beauty. It is obviously a great Rose. Mrs. J. H. Welch, Dean Hole, and E. E. Coxhead (cherry-red) were other notables. In Messrs. Prior's collection Lady Helen Vincent and Mrs. W. J. Grant, in addition to those named in the leading class, were good specimens. Forty-eight blooms, distinct varieties, brought three competitors, Messrs. Hugh Dickson, Limited, Royal Nurseries, Belfast, being placed first and staging many good examples. Here Nelly Parker (flesh-tinted white and a gold medal Rose of the occasion) was one of the most strikingly beautiful and distinct. It is a well-formed Rose with a presence of its own. Gorgeous was another telling variety (salmon and cream), but inadequately suggestive of an exquisite colour blend we do not recall in any other variety. Mrs. Charles Russell and the richly-coloured George Dickson were very fine. Mr. Elisha J. Hicks, Hurst, Berks, was second, prominent varieties being the new golden Margaret Dickson Hamil, George W. Waud, Prince Arthur (fine dark maroon), and Sarah Bernhardt. The class for twenty-four distinct varieties, three blooms of each, was less well represented, the quality less good. Messrs. G. and W. H. Burch, Peterborough, were first, their best sets being Margaret, Augustus Hartman, Mrs. Vanderbilt, Queen of Spain, and the cerise-red Lieut. Chauré; Messrs. J. Burrell and Co., Cambridge, second, William Shean and Mrs. T. Roosevelt being among their best, though none were free from weather blemishes. For twenty-four distinct varieties Messrs. Jarman and Co., Chard, staged an excellent lot and took first prize, the best bloom being a magnificent, well-coloured, finely-proportioned George Dickson, Mamie, Medea, Dean Hole, and Mme. J. Dupuy (gold and pink) being also remarked. Messrs. Chaplin Brothers, Waltham Cross, were second, but surely the firm were defeating their own ends by tilting their exhibit at such an angle as to render the reading of the names literally impossible without descending to our knees.

Messrs. Jarman were again first for twelve distinct varieties, three of each, Mrs. Foley Hobbs, St. Helena, and Mrs. C. Russell being good examples. Mr. Henry Drew, Longworth, was second, Lyon and George Dickson being among his best. For twenty-four distinct varieties Tea and Noisette (D'ombraïn Cup) the last-named exhibitor stood first, having exceptionally good examples of Mrs. Edward Mawley (silver medal), White Maman Cochet, Souvenir de Pierre Notting, Comtesse de Nadailac, and Molly Sharman Crawford (a lovely white); second, Messrs. D. Prior and Son, Colchester, who showed excellent blooms of Mme. Jules Gravereaux, Nita Weldon, and Molly Sharman Crawford. For twelve Teas and Noisettes Mr. J. Mattock, Headington, Oxford, was first, Mrs. Foley Hobbs and Molly Sharman Crawford being good. For sixteen distinct varieties, three of each, Messrs. D. Prior and Son

and Mr. H. Drew were the only competitors, and took first and second prizes respectively.

ROSES IN BASKETS.

These, as usual, constituted a leading feature of the exhibition, the generous contributions and fine quality throughout being the greatest possible tribute to the decorative or garden aspect of the flower in a year by no means kind. The three or four dozen blooms each basket contained, together with the abundance of buds, afforded evidence of a flower freedom so much to be desired. In the more important class for nine baskets of cut Roses, nine distinct varieties, each variety in a separate basket, Messrs. Hugh Dickson, Limited, Belfast, were first with a magnificent exhibit which included Ulster Standard (single crimson), Mme. Edouard Herriot, Irish Elegance (single), Mrs. George Shawyer, Mrs. David MacKee (cream), Mrs. James Lynas (blush), and Lady Pirrie. No praise would be too high for this exceptional exhibit; second, Messrs. Alex. Dickson and Sons, Newtonards, Co. Down, the pick of whose collection were Irish Fireflame, Mrs. H. Stevens (pure white), Lady Pirrie, Red Letter Day, Donald McDonald (reddish-scarlet), and Margaret Dickson Hamil, the two last-named baskets being selected and borne away by Her Majesty Queen Alexandra. In the class for five baskets of Roses, similar conditions, six collections were staged, the whole constituting a most imposing array. In this Mr. Elisha Hicks, Hurst, Berks, led with an excellent lot, the varieties being Joanna Bridge (blush-white, lovely form), Princess Mary (single crimson), Lady Hillingdon (of fine colour richness), Mrs. E. Powell (cerise-red), and Mrs. Dunly Best (soft apricot); second, Mr. G. Prince, Longworth, whose best baskets were Mrs. H. Stevens, Irish Elegance, Ethel Malcolm (blush), and Lady Hillingdon. For eighteen distinct varieties, seven stems of each, in vases, Messrs. Chaplin Brothers, Waltham Cross, were first, showing Red Letter Day, Mabel Drew, Lyon, Mrs. H. Brocklebank (white), Mrs. George Shawyer, British Queen (splendid white), and Old Gold. Messrs. D. Prior were second. For nine varieties, similar conditions, Mr. George Lilley, Yiewsley, Middlesex, who was placed first, showed General MacArthur, Mme. E. Herriot, Lady Pirrie, and Lyon (good). Mr. Elisha Hicks was second, Lady Pirrie, Lady Hillingdon, and Joanna Bridge being three of his best. For thirty-six distinct varieties, space allowed 14 feet by 3 feet, Mr. John Mattock, New Headington, Oxford, was first, his superb lot including the golden-yellow Iona Herdman, Mrs. H. Stevens (white), Rayon d'Or, Mme. Segond Weber, Simplicity (single white), and Silver Moon, also single. Messrs. Frank Cant and Co. were second.

For a representative group of Roses space not exceeding 250 square feet, Messrs. Wm. Paul and Son, Waltham Cross, were first, their most important item being Paul's Scarlet Climber, a brilliant Rose undoubtedly. Queen of Fragrance and Elise Robichon, the latter pleasing in bud blossom and leafage, were also shown. For a group 33 feet by 3 feet, Messrs. W. and J. Brown, Stamford, were first with an admirable lot, the outstanding feature being the arches formed by the single pink pillar Rose, Mrs. Rosalie Wrench, a welcome bit of colour in a variety of remarkable size.

In the amateur's division the big class for thirty-six blooms, distinct varieties, was strongly contested, no fewer than eight collections being staged. In this

the champion trophy, gold medal, and cash prize fell to Mr. Herbert Wettern, Oxted, in whose fine assortment the pink-flowered Wm. Shean secured a silver medal.

GOLD-MEDAL ROSES.

NELLY PARKER (flesh-pink and white), perfect form and of exceptional fragrance, from Messrs. Hugh Dickson and Sons, Belfast.

CHARLES E. SHEA (deep pink), in the way of Mrs. G. Shawyer, a variety of distinction and merit from Mr. E. Hicks.

HOLLAND HOUSE SHOW.

JULY 4TH, 5TH, AND 6TH.

THE summer exhibition of the Royal Horticultural Society was held in the grounds of Holland Park by kind permission of Mary Countess of Ilchester, and from every standpoint it must be considered a success. Smaller—decidedly smaller—than others that have preceded it, it was, notwithstanding, large enough to demonstrate, even in these strenuous times, that horticulture in all its branches is still conducted with much of its pre-war enthusiasm.

Hardy flowers, as on former occasions, were well to the fore, the great gathering everywhere revealing their summer wealth, beauty, and variety, and demonstrating in some measure an ever increasing popularity. The more imposing displays of *Iris Kœmpferi* which we have seen at this function in other years were, owing to the coldness of the season, absent. Roses were very fine, particularly from Mr. George Paul, of Cheshunt, who, unable to show at the "National" a day or two before, has probably rarely exhibited in better form or presented finer quality. Sweet Peas, too, were particularly good, those from Ireland of great excellence. Orchids have been seen on a much more lavish scale, though rarely of finer quality or so replete of the choicest and best. Orchard-house grown fruit trees in pots from Feltham, Strawberries from Bedford, and Cherries from Maidstone were the chief of the fruit exhibits shown. A collective exhibit of vegetable produce came from members of the Market Growers' Association. Following are some particulars of the show:—

HARDY FLOWERS.

The most sumptuous group of these came from

Mr. Amos Perry, Enfield, and while well conceived was also imposingly displayed. His group of Lilies was probably the richest ever staged, his collection of hardy Ferns magnificent. Everything, indeed, was on a lavish scale, and whether Lilies, Herbaceous plants, Water Lilies, or Ferns, everything exceedingly well done. Some 1,400 square feet were thus filled, the group well meriting the Coronation Cup—the highest award of the occasion—in addition to the gold medal it also received. Of Lilies alone there were much variety and charm in the hybrid Marhan set (*Martagon* x *Hansonii*), the varieties valuable alike for beauty and their easy culture. Miss Willmott and G. F. Wilson were among the best. The one parent, *L. Hansonii*, was in great form and is an excellent garden plant. The graceful golden-flowered *Roezli*, the still intenser yellow, larger flowered Amos Perry, the changeable *Washingtonianum*, with cernnum and *Krameri*, were among the more telling in a batch which impelled admiration. Brilliant masses of *Delphiniums*, a hundred or so of spikes of a sort, showed the distinctive worth of the best of these, though that named *D. Belladonna* semiplenum, with graceful spires of sparkling sky-blue flowers, appealed to us most

strongly. Around a pool containing *Nymphæas*, *Primulas*, *Sarracénias*, *Darlingtonias*, *Rodgersias*, and other suitable things were planted. The fine collection of Ferns adjoined, our regret being that we cannot more fully refer to them. The *Phloxes* from

Messrs. H. J. Jones, Limited, Lewisham, S.E., contained the best of these plants. Mrs. Alder (pearl-pink), Mrs. H. J. Jones (rose-pink), Mrs. John Meakius (salmon), Doris Meakins (white-pink eye), Violet Guest (rich salmon), and Rose Queen were among the more distinct.

Messrs. Wallace and Co., Colchester, showed well of hybrid *Eremuri*, the great wealth of spikes indicating the interest and wondrous variety now found in this unique race. *E. Warei*, *E. Bungei*, and *E. B. magnificus* were notable. Elsewhere in the group *Lilium pardalinum* *Johnstoni* and *L. Hansonii* were conspicuous, and not less so the fine summer *Iris* *Mon-aurea* and *Shelford Giant*. *I. spuria lilacina* is of a distinct type and very pretty, the intense royal purple of *I. Delavayi* also appealing. *Delphiniums* were also a host in themselves, the richly-coloured Water Lilies very attractive.

Mr. J. C. Allgrove, Middle Green, Langley, Slough, had a large exhibit of choice things, in which such *Primulas* as *Poissoni*, *capitata*, *Bulleyana rosea* (a lovely plant), and *Beesiana* were seen to advantage. In the cut state the rare *Magnolia parviflora* (white with maroon centre) was seen in plenty, and behind it a remarkable lot of *Fremontia californica*, whose golden cups are rarely seen in such profusion. *Philadelphus Virginalis* is the best of its class, the handsome semi-double flowers of the purest white. *Eremurus Warei*, *Rodgersia æsculifolia*, and *Lavatera (Malva) Olbia grandiflora* were also remarked.

Messrs. Harkness and Son, Bedale, displayed a brilliant lot of *Gaillardias*, *Peter Brownridge* and Mrs. MacKellar occupying a central place. Their gold and crimson flowers were very fine. *Verbascums*, too, were imposing; *Britannia* (bronze), *Lady Allison* (rich golden), and *Joss Richardson* (bronze and yellow) strikingly ornamental. *Giant Oriental Poppies* *The King* (crimson) and *The Queen* (pink) were noted.

Messrs. Bunyard's group of herbaceous plants was most tastefully done, the items easily and naturally disposed throughout. The firm's new *Delphinium*, *Queen Mary* (brilliant sky-blue with large white eye), constituted a good centre-piece. On right and left flanks were equally good groups of *Alake* (rich purple) and the indispensable *Rev. E. Lascelles*, the pale-blue, dark-eyed *Jessica* also appealing. *Iris Shelford Giant*, an ochroleuca hybrid of 5 feet to 6 feet high, also demonstrated its importance. Alpines were in the margin.

Messrs. Blackmore and Langdon, Bath, showed strongly of *Delphiniums*, three varieties, Mrs. Shurley (*heliotrope-mauve*), Mrs. A. J. Watson (deep mauve), and Mrs. Colin McIver (deep mauve, white centre) gaining Awards of Merit. These are important colour additions to the group and handsome varieties withal. *Torquoise* (light blue) and *King Bladud* (a double dark sport from *Rev. E. Lascelles*) were among other good things.

Mr. G. W. Miller, Wisbech, had a great gathering of *Lilium giganteum*, some six dozen or so spikes being staged as a centre to a comprehensive group. So remarkable a lot of this Lily has never before been seen at one of these meetings. The giant spikes, towering to 7 feet or 8 feet high, made an imposing exhibit, the

drooping, white, crimson-stained flowers a great feature. Many other hardy flowers—notably *Potentillas* and *Delphiniums*—were on view.

Mr. J. Box, Lindfield, showed well of *Delphinium Rev. E. Lascelles*, *Erigeron B. Ladhams*, and the fine *Campanula glomerata superba*, a giant compared with *C. g. speciosa* of a quarter of a century ago. The brilliant and graceful *Lilium Grayi* and a handsome lot of *L. Hansonii* were features of a good group.

Messrs. J. Piper and Sons, Bayswater and Barnes, arranged a streamlet, grouping the moisture-loving *Primulas* *Bulleyana*, *Beesiana*, and *Iris Kœmpferi* suitably at the sides. In shade a little removed, *Lilium regale*, a couple of dozen or so, made a fine picture, while on a rock bank at the extreme left the lovely pale-blue trailing *Gentiana Przewalskii* was most pleasingly colonised. In a group from

Messrs. Barr and Sons, Covent Garden, W.C., the finest hardy plant novelty of the meeting—*Campanula persicifolia* *Telham Beauty*—was seen. Of giant stature—4 feet or more—its refined, pale-blue bells are in like proportion, the variety head and shoulders above all else in the Peach-leaved section. A good addition to its tribe, it is an acquisition to hardy plants as a whole. Early *Gladioli* were very good, such distinct varieties as *Fiery Knight*, *Crimson Queen*, and *Peach Blossom* standing out well. *Delphiniums* gave a feast of colour.

Miss Willmott, Warley Place, had a dozen or so spikes of *Gentiana lutea*, some showing shades of bronze. *Salvia Warleyensis* (dusky purple) received recognition among new plants. *Lilium mirabile* appeared from the material displayed to be a dark-stemmed, small-growing *giganteum*.

Messrs. George Jackman and Sons, Woking, showed *Delphiniums*, *Capri* (pale blue), *King of Delphiniums*, and *Rev. E. Lascelles* being very fine; also *Lavatera Olbia* and *Astilbe gloriosa*, the best coloured form, among many things.

Messrs. T. S. Ware, Limited, Feltham, showed the handsome *Verbascums* *Lady Allison* (gold and bronze) and *Lady Havelock Allen* (dark bronze), together with *Heucheras*, *Pæonies*, *Erigeron Edina* (a pretty white-flowered sort), and much else in season.

Messrs. J. Waterer, Son, and Crisp, Bagshot, had a nice lot of *Delphiniums* in good sorts, also *Campanula persicifolia* *Wargrave Blue*, a very distinct and good form. *Spiræa digitata nana*, 6 inches or so high, was nicely grouped. Dwarf *Campanulas*—e.g., *pulla*, *pulloides*, G. F. Wilson, and others—were freely disposed, among other things, on a rock bank.

Messrs. James Kelway and Sons, Langport, contributed a large assortment of *Delphiniums*, great spires in the main of these best of summer flowers being shown. *Star of Langport*, *Dusky Monarch*, *Smoke of War*, *Effective*, and *Lord Holland* (deep mauve) being some of the more notable.

Messrs. John Forbes, Limited, Hawick, in the open air showed a brilliant group of *Phloxes*, *Pyrethrums*, *Tufted* and other *Pansies*, and *Pentstemons* in much variety. Messrs. Godfrey and Son, Exmouth, had an excellent strain of the *Cup and Saucer Canterbury Bells*. Mr. B. S. Ladhams, Shirley, Southampton, brought a rich assortment of *Pinks*, hardy, free, and fragrant. Messrs. R. H. Bath, Limited, Wisbech, filled a considerable table space with *English Irises* and *Early Gladioli*, while from Messrs. Lilley, Guernsey, came a most interesting collection of *Ixias*, *Sparaxis*, *Brodiaea*, *early Gladioli* and others of a bulbous nature. The most

graceful subjects of the group were *Sparaxis pulcherrima* and its white variety and *Moræa iridioides*, a plant of considerable interest and charm. *Pæonia lutea grandiflora* and *Lilium regale* were of interest in a group from Mr. A. D. Thompson, successor to Thompson and Charman, Bushey, Herts.

Messrs. H. Cannell and Sons, Eynsford, Kent, showed a particularly fine strain of Canterbury Bells of the Cup and Saucer section, also such brilliant *Delphiniums* as Mrs. Robert Cobb (a magnificent variety of azure-blue and white), Lullingstone (deep blue, white centre), Prince of Naples (dark purple), and Eynsford Beauty (of rich metallic purple hue). *Pæonies* and many other hardy flowers were also well shown.

FRUIT AND VEGETABLES.

The exhibits of fruit and vegetables were not numerous, but there was, speaking generally, evidence of quality and culture of a high order. Of

Vegetables there was a remarkable and extensive collection, or, rather, a series of collections, staged by various growers and exhibited under the auspices of the Market Garden, Nurserymen, and Farmers' Association. The staging of the various productions was not, as might be expected, carried out in that elaborate and artistic manner which visitors to these exhibitions are wont to see and admire, but of the quality of the individual exhibits there could, with but few exceptions, be no two opinions. Taken collectively, the outstanding features were excellent medium-sized and very fine heads of Cauliflowers, very fine, solid-hearted Lettuces of both the Cos and Cabbage types, typical Globe Artichokes, excellent Turnips and Carrots, and model Mushrooms. There were also green Gooseberries in variety, Black and White Heart Cherries, Black Hamburg and Buckland Sweetwater Grapes, and Cucumbers and Tomatoes. To the Association great credit is due for their enterprise, and they are to be congratulated for bringing such a fine collection of market-garden produce together and exhibiting it for the benefit of the public at large. Coming to

Fruit, the Messrs. Laxton, of Bedford, showed a large number of baskets filled with fine examples of Strawberries of their own raising, such as King George V., Bountiful (which has the reputation of being a very heavy cropper), The Admiral (also said to bear heavily), Royal Sovereign, Latest, etc., which attracted great attention and were much admired. The same firm also had on view a promising new variety of Red Currant named Perfection, the individual berries large, the bunch of great length, and containing upwards of twenty-five berries. Two trees in pots were also exhibited to show the productiveness of this novelty.

Messrs. Stuart Low arranged a collection of pot-grown Vines, Peaches, Brown Turkey and St. John Figs. The latter were freely fruited, but the fruit generally was in an unripe condition. Among the Vines, the now little known and grown variety Grove-end Sweetwater was noted.

Messrs. Bunyard and Co., of Maidstone, staged a comprehensive collection of Cherries in pots, all carrying excellent crops of fine and highly developed fruits, which formed a highly instructive object lesson to all interested in the pot culture of fruit-trees and of Cherries in particular. Varieties calling for special mention are *Noir de Schmidt* (a remarkably large fruit, glossy black in colour), *Noir de Guben*, and the very fine black variety *Emperor Francis*, a dark-red *Bigarreau*, *Napoleon Bigarreau*, *Black Circassian*, and *St. Margaret's* or *Tradescant's Black Heart*. Excellently fruited examples of *May Duke*,

Late Duke, *Governor Wood*, *Kentish Bigarreau* or *Amber Heart* were also noted. The collection also contained a specimen of the true, useful, and free-fruited variety *Kentish Red*. The premier exhibit of orchard-house fruit-trees in pots was contributed by the

Messrs. Richmond and Sons, of the Royal Nurseries, Feltham, which contained finely-fruited examples of *Peregrine Peach*, *Early Rivers Nectarine*, *Green Gage*, *Jefferson* and other varieties of *Plums*, *Brown Turkey Figs*, *Pears*, and *pot Vines* in fruit. Every specimen bore the hallmark of high culture and showed that the exhibitors have a perfect knowledge of the requirements of fruit-trees grown on this principle. This was a truly laudable exhibit and justly merited the gold medal awarded it.

Owing to want of space we are compelled to hold over notes as to the *Roses*, *greenhouse plants*, *Orchids*, etc. A detailed list of the certificated plants and medals will be found in our advertisement columns.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Moving Roses (Bog Cotton).—All depends on the care you take in the removal of the *Roses*. In the case of those that have been planted three or four years it would be very risky, but those that have been planted, say, one year could be easily moved. On the whole, it would be better, we think, to start with young, vigorous plants, which would, if carefully planted early in the coming autumn, have time to root before the winter is with us.

Mulching Carnations (H.).—Carnations, as a rule, do not like mulchings of raw manure, but if you have any old hotbed manure, leaf-soil, or even old pot soil, you can spread about the plants, which will help to check evaporation, it will do them good. Should you desire to layer some shoots of the best varieties later, you will find the mulch of old potting soil very helpful for that purpose, and especially if when layering you add some sharp sand. When the weather is dry a watering of liquid-manure weekly will do much good.

Potting Chrysanthemums (J.).—In preparing *Chrysanthemum* compost break or chop up your turfy loam well, but do not sift it. Mix with two parts of this loam one part composed of old hotbed or Mushroom-bed manure, this in the greater proportion, a small quantity of bone-meal or ground dust, and some sharp gritty sand; a moderate quantity of soot also may be added. If you use blood-manure, let it be in very moderate quantity. It is not desirable to induce a coarse wood and leaf growth at the first. The best time for feeding is with liquid-manures moderately after the large pots have become filled with roots. The addition of strong, coarse manures to the soil early causes it presently to become sour and pasty. In potting use turfy pieces on the drainage, and ram the soil firmly round the balls of roots.

Growing Violets (Bog Cotton).—Runners should be put in every year, April being the best month for doing this. In the case of very light soil, which always suffers if the summer is very dry, a little shade is beneficial. On holding soils, *Violets* are just as well, if not better, planted in the open. This applies to double or single *Violets* intended for frames or outdoor culture only. Ground for *Violets* must be of good quality, and be well prepared by trenching or deep digging, with plenty of manure added, and, if possible, some leaf-mould. The single varieties, on account of their stronger growth, require more room than do the double forms. Single varieties of the more modern kinds, such as the *Princess of Wales*, flower freely on the runners which issue from the parent plant, and for this reason such runners may be left. The double varieties, on the contrary, must have the runners removed, so as to strengthen the crowns which give the finest blooms. Good varieties are:—*Singles*: *Princess of Wales*, *Admiral Avellan*, *California*, and *Wellsiana*. *Doubles*: *Mrs. J. J.*

Astor, *Lady Hume Campbell*, *Mme. Millet*, and *Marie Louise*. You will find an article dealing more fully with the cultivation of *Violets* in our issue of March 13th, 1915, page 155, a copy of which can be had of the publisher price 1½d. post free.

FRUIT.

Insects spoiling Strawberries (J. R. Ship-sides).—Your *Strawberries* have been injured by the spotted snake millipede (*Blanjulus gutturalis*), a very destructive pest to that fruit and to the roots of many plants. Liquid insecticides have but little effect on them. One of the many soil fumigants will destroy them, and they may be trapped by burying pieces of Turnip, Mangolds, etc., just below the surface of the soil. Stick a small wooden stick into each bait to show where they are placed, and examine them every morning.

MISCELLANEOUS.

Management of gold-fish (H. T. Shawcross).—*Vermicelli* is the best food for gold-fish. It should be finely crushed, and thrown sparingly into the water, taking care not to supply more than will be consumed at once, that none may accumulate at the bottom of the tank. The fish when "on the feed" will take the vermicelli as it slowly sinks, and will soon learn to take it eagerly. A little raw lean meat shredded fine is also good for them, and small garden or water-worms may be given from time to time. All gold-fish tanks should contain a number of water-snails, as they not only keep the water sweet by consuming decayed vegetable matter and so forth, but their eggs and fry afford excellent food for the fish. If your tank is not furnished with sand and water-plants it would be well to supply these as soon as possible. The water should not be changed, but only sufficient added to make up for evaporation. Feed about three times a week in mild weather.

SHORT REPLIES.

G. G.—Impossible to assign any reason without seeing the bulbs.—*Rev. W. F. A. Lambert.*—The Board of Agriculture and Fisheries, 4, Whitehall-place, London, S.W., issue a pamphlet (No. 250), "Fruit Bottling for Small-Holders." This can be had from the Board. There is no need to stamp your letter of inquiry.—*Mrs. Barron Newell.*—Any nurseryman who makes a speciality of greenhouse plants could supply the *Coleus* you inquire about. It used to be grown at one time largely for the flower garden.—*C. Barnby Smith.*—1, We have failed to trace *Wahlenbergia tasmatica*. Your best plan will be to treat it as you would the ordinary forms. 2, *Gentiana Kurroo* is offered by Mr. Amos Perry, Hardy Plant Farm, Enfield.—*J. A. J.*—"Root and Stem Vegetables," which can be had through any bookseller, price 1s. 6d. The best book on the subject is "The Vegetable Garden," from this office, price 15s. net.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*Frank Bennett.*—*Sidalcea malvæflora* (Gray).—*Matlock.*—1, *Campanula pusilla*; 2, *C. muralis* (syn. *C. Portenschlagiana*).—*F. M. A. H.*—One of the many varieties of *Mesembryanthemum*.—*A. M. L.*—A, *Dianthus* sp.; B, *Philadelphus* sp.; C, *Veronica Traversi*. Specimens very poor, hence the difficulty in naming more definitely.—*Miss A. Donovan.*—1, The white form of the *Red Valerian* (*Centranthus ruber*); 2, *Centaurea macrocephala*.—*M. R. Hearn.*—1, A pink form of *Lychnis chalcidonica*, not common, but not equal to the type; 2, *Hieracium aurantiacum*.—*C. G.*—*Olearia Gunniana*.—*G. Strickland.*—There are so many *Speedwells* like the one sent that to name it rightly we should thank you for a better example of the flowers and shoots pressed between sheets of paper.—*E. H. S.*—Your two specimens are the *Masterwort* (*Astrantia major*) and *Symphytum caucasicum*. When sending plants for name in future, please number each specimen.

SAVING LABOUR AND GAINING BEAUTY.

My lake, with Water Lilies in large groups, has had for many years a turf path a mile long round it. As the water-side vegetation and that on the land side near are vigorous it was thought essential to have a mown path all round, but owing to scarcity of labour mowing had to be discontinued. I lately paid a visit to the scene and found the path full of native flowers—Clovers, Bedstraws, and other charming wild flowers—the effect being many times better than when the path was regularly mown. So we have proof here that paths that are commonly mown may well be left alone, with the result that they have a much better effect. In fact they were never half so pretty when they were mown every week. Now we do nothing to them beyond sending a man round with a fag-hook occasionally to knock away any wandering bough or coarse tuft.

In the woods also we have some miles of rides which were mown every summer at the cost of much labour even in normal times. In the last two years we have let them alone and have not suffered any inconvenience from it. The rides are 18 feet wide and most important for view and air and other reasons, but so far they are none the worse. It may be that boughs and growths will need to be controlled every few years. In some country places it was the custom to mow many acres, and the owners were often proud of it—in fact, on as many as 40 acres the Grass was kept short.

The fact is that a lawn is made much more beautiful without any such attention, letting the natural flowers of the meadow be seen, and only cutting it when the Grass is ripe for hay. Not only is there the saving of labour but there is an enormous addition of beauty to the lawn if one has taken the trouble to put in Crocuses, Grape Hyacinths, Blue Wind-flowers, and all the flowers of early spring which do well in it, and disappear before the mower wants the Grass. Here we have a succession of beauty without cost beyond putting the things in in the autumn. Such bulbs are often sold at low prices by the thousand. The hay is quite as good, and some of the early things, like the Crocus, will have left no trace of leaf by the time the hay is cut. It is desirable to keep out any plant which is injurious to stock, and for that reason we are inclined to exclude the Narcissi and keep them more for copses and woods. A few groups are little

harm. The mowing of Grass paths should be limited to those among the evergreens and a few near the house. This is easy with the light hand-mowing machines of the present day. It is surely an advantage to get rid of the horse or pony, still more so the horror of a motor mower. By reducing the area mown to necessary limits on Grass paths or used playground the mowing may be easily done by a strong youth and one of the best small mowers. It is a clear gain to get rid as far as may be of any noise in mowing. W.

NOTES OF THE WEEK.

Gentiana Przewalskii.—A distinct and beautiful Gentian with a trailing habit. It may vary a little from seed; the one I saw was a rich fine purple. Among all the beautiful Gentians this is the one we cannot do without. It is growing in flinty soil at Hillbrook Place. A native of China and one of the best.—W.

Sisyrinchium striatum (Rush Lily).—For the waterside nothing can be prettier or more effective than a group of this plant. The narrow leaves, each about 1 foot in height, of a bluish glaucous green, harmonise with the creamy-lemon flowers, about a dozen of which are carried on a narrow spike about 2 feet high. It is rarely grown, but is quite hardy, and no water-side planting should be without it, but it must be grouped and not planted in twos or threes.—FRANK CRISP.

Fremontia californica.—I have had the rare pleasure of seeing this beautiful shrub in fine flower. Originally planted against a wall, it leant away from this and formed itself into a very graceful bush some 10 feet high, and full of lovely blooms. It is a precious plant and is growing in warm, flinty soil at Hillbrook Place, and is happy there. I have made several attempts to grow it in quite a different kind of soil without any success, but must go on trying it. Raising the plant from seed should be easy.—W.

Eucryphia cordifolia in Scotland.—There are a few good plants of Eucryphia pinnatifolia in the south-west of Scotland, notably the fine specimen in the garden of Mr. W. D. Robinson-Douglas, at Orchardton, but it is rare to meet with the newer Eucryphia cordifolia, a handsome plant, both in foliage and flower. There are, however, two good plants at Monreith where, unfortunately, they are often cut by frost in spring, and thus prevented

from flowering. This year, however, these plants have escaped and will probably bloom in due course.—S. ARNOTT.

Meconopsis Wallichii.—I had rather a varied experience with this, and have only lately seen it in a fine state. What seemed to suit it so well was a little trickling water running through boggy soil. In that it stood up 6 feet high, and the blue flowers seen at that height were more attractive than usual. I have tried it in various soils and never got it half so good. Hillbrook Place, mid-July.

Gaultheria Shallon.—This should be more extensively grown than it is. While the members of the Bournemouth Gardeners' Association were recently inspecting the trees and shrubs in the charming grounds of Branksome Dene, by the kind permission of Mrs. M. S. Cassel, they were much interested in this shrub on account of its thriving condition under large Fir and other trees, on dry banks, and in sand and peat. In places the whole of the surface was thickly covered with handsome foliage to a height of about 3 feet.—BOURNE VALE. W.

Tree Lupins should not die in Sheffield, though I can imagine they will not flourish as they would at Boar's Hill and neighbourhood. I have a yellow one here, about four years old, only protected from the north by a Privet hedge. It grows in about 6 inches of made sandy soil on the top of very heavy yellow, shaly loam. It was quite ready to grow 5 feet high, only what rose above the hedge was broken by recent northerly gales. It is quite 6 feet in width and covered with bloom. The whole garden here is on a northerly slope and the winter climate is not exactly balmy, no better than at Sheffield.—L. J. ROGERS, 6, Hollin Lane, Leeds.

The Californian Lilac (Ceanothus thyrsiflorus).—This, the hardiest of the early-flowering Ceanothuses gives excellent results in the open ground in many parts of the country. In Miss Willnott's garden at Great Warley, Essex, there is a bush 30 feet high, while there are several fine bushes at Kew, the largest of which was destroyed by wind a few years ago. The blue flowers, produced in dense inflorescences, each 2 inches or 3 inches long, are at their best during late May and June. Introduced from California in 1837, it is by no means such a common shrub as its beauty warrants, and it might well be substituted for one of the commoner evergreens, which are all too often seen in our gardens. Even where it will not succeed in the open it might well be grown against

a wall. Given well-drained, loamy soil, and a position sheltered from rough winds, it grows rapidly, and soon forms a bushy specimen 12 feet or more high and as far through. In the variety *C. t. griseus* both leaves and inflorescences are longer than those of the type, whilst the flowers are lilac in colour. It appears to be rather more tender than the type, but gives excellent results with a little shelter. Both the type and variety can be increased by cuttings inserted in sandy soil in a close fraue in July.—D.

Mistakes as to quantity.—I have been getting together a few plants of the beautiful Geum, Mrs. Bradshaw, hoping to make a group of it, and lately I went to a great garden and saw there hundreds of yards of it in a straight line. In the same place hundreds of other plants were seen in the same way. No greater mistake in emphasising a plant could be made. It takes away all chance of admiring a plant for its beauty which a group of a dozen or less would have well shown.—W.

A charming combination.—In the garden of Sir Herbert Maxwell at Monreith, Wigtonshire, a very beautiful effect is produced by a large bush of a white Rhododendron, above which rises a tall Tamarisk, whose sprays of pink, feathery flowers droop over the Rhododendron and produce a cloud-like appearance. The combination is an exceedingly beautiful one which has pleased me on former visits, and which had lost none of its charm to me when I saw it again on July 1st.—S. ARNOTT.

Rosa rugosa in a seaside garden.—This Rose does well in a garden on the edge of the cliffs in Bournemouth. The plants are growing at the edge of the cliff and are exposed to the strong winds that blow from the sea. The winds bring drift sand with them and deposit it on the beds, the roots of the Roses in some cases being deeply buried in the sand. The foliage is healthy and the flowers pure in colour. Owners of gardens near the sea may plant this Rose freely in the most exposed positions, and if they cut them hard back the resultant shoots will be very strong.—BOURNE VALE.

A good plant of Daphne Cneorum.—It is always pleasing to see a good plant of *Daphne Cneorum*. Mr. W. D. Robinson-Douglas has a very good one in his garden at Orchardton, in the south of Kirkeudbrightshire, where it is thriving specially well. The plant in question is fully 3 feet across each way, and not only looks healthy but blooms well. The branches are layered in the same way as Carnations, and stones are laid over them to keep them in position. As the branches extend they are again layered. No special soil beyond that for other rock garden shrubs is employed.—S. ARNOTT.

Cupid Sweet Peas.—I thought that these dwarf Sweet Peas had, long ago, been relegated to obscurity—from which they ought never to have emerged—and I was rather surprised the other day to come across a batch of them in bloom in a greenhouse. They were growing in 6-inch pots, and, I must in fairness admit, they had done very well. The variety was a pink and white flowered one. The seeds were sown in March and thinned down to a couple in each pot. I was told that by very careful watering the old failing of the Cupid Sweet Pea—bud-dropping—could be avoided, and that to further that end no liquid or artificial manure ought to be given. I would be loth to devote pot-room, not to speak of time and trouble, to these capricious and insignificant members of a meritorious family.—W. McG., *Balmoe*.

Solanum crispum in Scotland.—The beauty of *Solanum crispum* has often been referred to in your pages, but it is not generally known that it is quite hardy in some parts of Scotland, particularly the south-west and the more favoured portions of the east coast. At Culzean, where there is a noteworthy collection of uncommon shrubs, *S. crispum* does well and blooms very freely. Its purple-blue flowers are welcome, and give an effect not commonly met with among the hardier climbing shrubs.—A.

Ourisia coccinea in sun and shade.—The curious ways of *Ourisia coccinea* are well illustrated by two plants growing in the moraine of Mr. W. D. Robinson-Douglas, at Orchardton, Castle Douglas, Kirkeudbrightshire. They are within a yard of each other and are both growing in little basins in the rocks which crop out of the moraine. One is slightly shaded by the small boulder against which it is planted, while the other is in full sun. The slightly shaded one is a picture of health and beauty, with long stems, from which hang the brilliant scarlet flowers. I have never seen this plant finer than at Orchardton. On the other hand, the plant in full sun does not look nearly so happy, and there is not a single flower. Possibly there may be a little difference in the moisture retained in the basin, but the slight shade seems to be the cause of the difference.—S. ARNOTT.

Our native Lady's Slipper (*Cypripedium calceolus*).—On a recent botanical expedition it was my good fortune to come upon a patch containing upwards of twenty plants. A party of Yorkshire botanists and myself had been searching for the plant for a whole day; indeed, our search had been continued for upwards of thirty years, but this was a special day set apart to see if we could find the plant in one of its well-known habitats. The evening was getting far spent, and my two well-known friends had to return home to Thirsk. Not having any urgent calls upon my time, I determined to continue the search. At last I was rewarded with a sight of not one, but at least twenty robust, healthy plants. A friend of mine has also found it wild in one of its old habitats near Answick, near Settle.—WILLIAM STANSFIELD, in *Gardeners' Chronicle*.

[It is to be hoped these interesting localities will be guarded with care against thieves of roots for sale or of specimens for herbaria, neither object nearly so important as keeping safe these last localities of the most charming of our native Orchids.—ED.]

Rosa gallica Kizanlik.—From the Royal Nurseries, Exeter, we have a bunch of this, from which the attar of Roses is distilled. In a very useful work published in 1871, entitled "Pharmacographia: A History of Drugs," we find the following: "The chief locality for attar of Roses, and that by which European commerce is almost exclusively supplied, is a small tract of country on the southern side of the Balkan mountains in the Turkish province of Rumelia. The principal seat of the trade is the town of Kizanlik, in the fine valley of the Tunja. The other important districts are those of Philippopolis, Eski Zaghra, Yeni Zaghra, and Tchirpan, which, with Kizanlik, were estimated in 1859 to include 140 villages, having 2,500 stills. The Rose is cultivated by Bulgarian peasants in gardens and open fields, in which it is planted, in rows as hedges, 3 feet to 4 feet high. The best localities are those occupying southern or south-eastern slopes. Plantations in high, mountainous situations generally yield

less, and the oil is of a quality that easily congeals. The flowers attain perfection in April and May, and are gathered before sunrise. Those not wanted for immediate use are spread out in cellars, but are always used for distilling the same day."

Mimulus Whitecroft Scarlet.—This, referred to in a note by "W." on page 293, is worth growing. "W." states that "these flowers have in my soil a way of leaving without notice. They may want frequent division." I have had the same experience, and this is specially the case in dry soils. In such it is not only safer to divide up the plants every two years at least, but it is frequently advisable to remove them to another place in the garden or to give them fresh soil. Moisture is all important, but I think the scarlet varieties derived from *M. cupreus* are not so long lived as those with the blood of *M. luteus* in them. Some of the latter I have very fine by the margin of a little pool with their feet in the water.—S. ARNOTT.

A modest rock garden.—The illustration of the rock garden on page 299, with the accompanying note by "W.," should be of considerable service, especially at the present time when elaborate rock gardens, requiring large quantities of stone and soil, and costing a good deal for labour, are out of the question. It can never be too strongly emphasised that rock plants of most kinds can be grown satisfactorily on low rockwork, and frequently far better than on some of the elevated piles upon which they are placed without much consideration for the well-being of the plants. A friend of mine grows his plants on a low rockery—more correctly a rock bed—which at no part is 3 feet above the level of the surrounding ground, being simply a mound of good soil edged with stones and with larger blocks set in the ground here and there and rising above the level so as to give shelter and shade where required. Here he grows many choice alpine plants with much success. His plants look well, both in respect of their health and beauty. They are much more easily attended to than on large, high rockwork, and the whole rock bed cost him only a few shillings for material and cartage.—S. A.

The Partridge Berry (*Gaultheria Shallon*).—This fine dwarf evergreen shrub from Western North America is very useful as a carpet between trees in the foreground of shrubberies, or in any open position where a taller growing plant would be out of place. I have used this beneath Pine and Birch trees in the warm, sandy soils of Surrey, where it quickly became a dense carpet of healthy growth. Here (Sussex) it is growing in full sunshine on a poor piece of clayey ground, and in this position it has become a perfect thicket, and at the present time (June 5th) is a mass of large white, and in some cases pink, Andromeda-like flowers, which are freely produced in racemes each from 4 inches to 6 inches in length at the extremity of the past season's growths. When growing close together the growths draw each other up and are then very useful for cutting. In autumn these are succeeded by numerous large, purplish berries, juicy and not unpleasant to the taste. I have seen this very happy in moist and cool, shady places near the water side, but whereas the plants were quite healthy, flowers and berries are not so plentiful as when it is grown fully exposed to sunshine. It is a splendid covert plant, spreading freely by underground suckers, and if left to itself will quickly over-run a considerable area and furnish excellent cover for small game.—E. M.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

CORONILLA IBERICA.

THIS, when seen in a broad spreading mass, as shown in the illustration, is very attractive, the bright yellow flowers being well set off by the deep green foliage. It is indifferent to periods of dry weather and shows no signs of weariness in a very hot season. It is not suitable for the small rock garden, as it grows very rapidly and requires a considerable amount of space, but where the rock garden is of considerable extent it is valuable. It is a capital plant for a dry bank or very dry, sun-burnt spots, where little else will thrive. T. P.

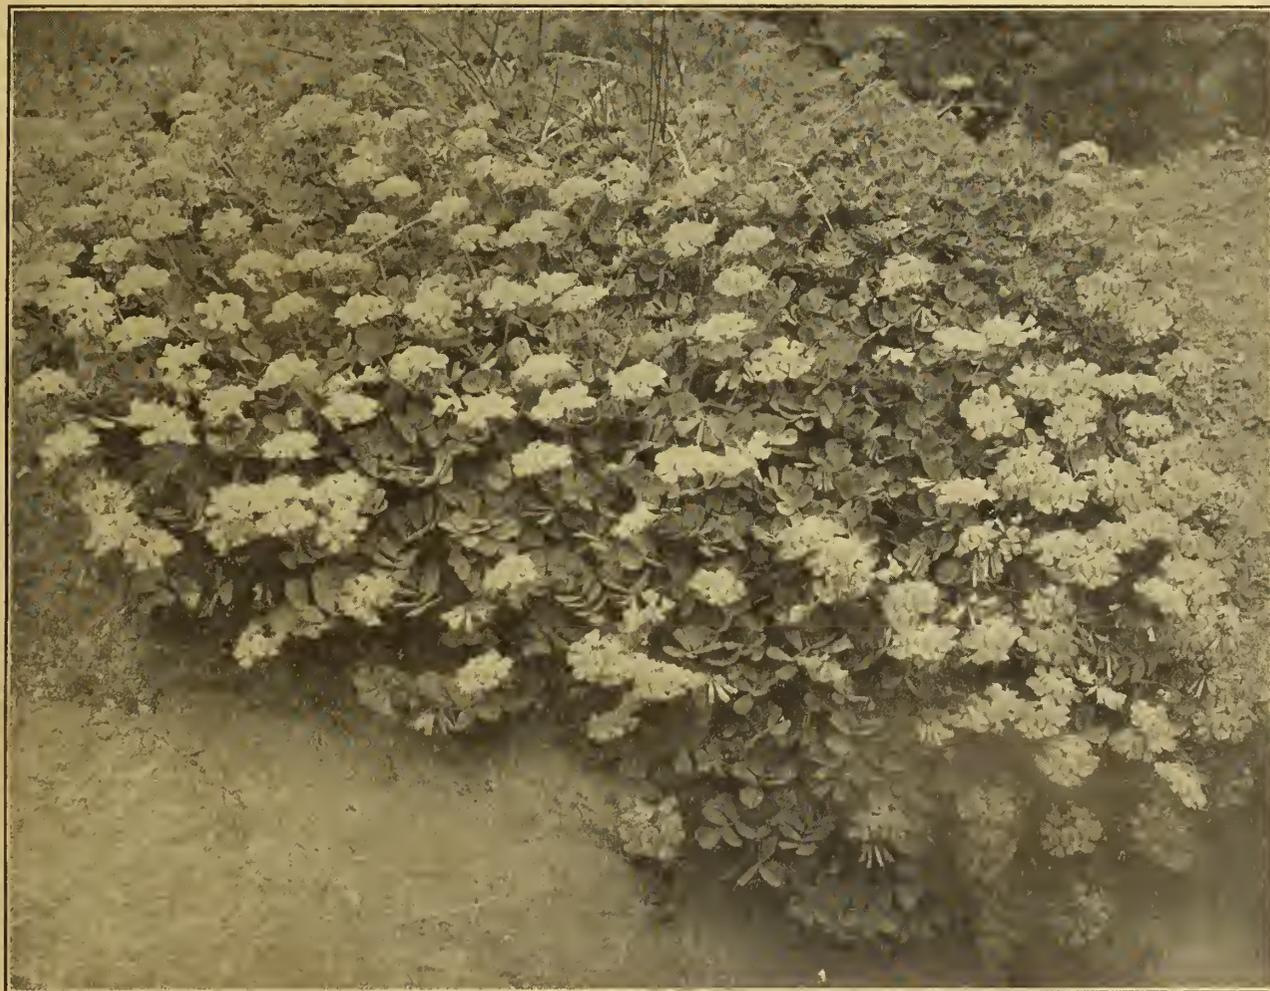

passes on his way from Western Szechuan to Tibet. According to Wilson, these valleys, though watered by the Tung, Yalung, Dre, and Min rivers—caveshoots for the snows that slip off the roof of the world as soon as the sun begins his annual round, are almost desert-like because of an abnormally warm, dry climate, yet boast a flora limited in extent, it is true, but of extraordinary beauty and interest. Of them he writes: "To garden lovers everywhere these valleys are of especial interest, inasmuch as they are the home of many beautiful Lilies. Each of these valleys has species or varieties peculiarly its own, which range up to about 8,000 feet altitude; yet while very local, these Lilies are, numerically, extraordinarily abundant. In late June and July it is possible to walk for days through a

there is probably nothing to fear for it on the score of cold. *L. regale* is unique in many ways, but in none more than the wonderful germinating power shown by the seed, and I have noticed that seed sown in any month of the year germinates quickly and comes up like Cress. Unless it develops some constitutional weakness not at present apparent, *L. regale* may be regarded as the type of a perfect garden Lily.—A. GROVE in *Country Life*.

NOTES AND REPLIES.

Bedding plants.—What bedding plants can I put in now besides *Violas*, *Pelargoniums*, and *Asters* in a warm, exposed position? Is it too late for *Lobelia cardinalis*? I like scarlet best for colour.—BUTLER, *New Forest*.

[If you can obtain the plants, which is rather doubtful, seeing the season is so

Coronilla iberica.

LILIUM REGALE.

HAVING been introduced as *L. myriophyllum*, this is still often referred to under that name, furnishing one more illustration of the confusion that follows in the wake of a mistake in the nomenclature of a plant once it has been launched on the sea of horticultural "literature." *L. speciosum* and *japonicum*—both old garden friends—are other examples of this, for they are frequently referred to by slipshod horticultural scribes as *lancifolium* and *Krameri* respectively. E. H. Wilson, whose discovery of *L. regale* alone must surely leave gardeners for ever in his debt, stumbled across it in the Min Valley, one of several long and comparatively narrow defiles in that no man's land—as yet but vaguely indicated even on the latest Mission maps—across which the traveller

veritable wild garden dominated by these beautiful flowers."

Of *L. regale* it can be said that no other Lily has taken so spontaneously and so quickly to conditions so entirely different to those obtaining in its native wilds. It seems happy enough in decent loamy soils and is not seriously crippled either by prolonged drought or, what is more wonderful still, the winter wet that of late years has been so regular a feature of our island climate. At any rate, the plant has had more than a taste of each since it has been our guest, and seems none the worse. *L. regale* has had no opportunity of showing us how it will fare in an Arctic winter, because there have been no prolonged frosts worth recording of recent years, but it has come unscathed through several rigorous winters in the United States, so

far advanced, there are *Zinnias* and *Phlox Drummondii* to be had in various shades of scarlet. Fire King *Antirrhinum* would also please you if you could purchase young plants and grow them on, as they would bloom abundantly in autumn. Tuberos *Begonias* of the desired colour should be obtainable, and no doubt *Lobelia cardinalis* also. This last would have to be kept well supplied with water, seeing the position is warm and exposed. Then there are *Fuchsias* and *Petunias*, which would make a fine display in such a position, although the flowers would not be scarlet. The dwarf forms of *Nasturtium* are to be had in a colour approximating more nearly to scarlet than the last two named plants. Although *Pelargoniums* are mentioned, do you include the Ivy-leaved section, as several varieties of

these of the desired tint are to be had? The single Aster Scarlet Southcote Beauty is a gem, and would please you if you have not already got it.]

Crambe cordifolia.—This makes a fine specimen plant if given plenty of room, and never fails to attract attention when in blossom. It is a very vigorous grower, and the inflorescence, when well developed, will often measure several yards in circumference. It is of graceful habit and does well for cutting, the sprays of small white flowers looking very pretty either by themselves or mixed with others. Although of such vigorous growth it does not quickly exhaust the soil as many strong-growing plants do, but sends its long, thong-like roots far afield. Its main flowering is in June, but it often blooms again in September. One excellent point in its favour is that the flower-stems are so strong that they require no staking.—W. O.

Single Dahlias.—To a great extent single Dahlias have lost the popularity which they enjoyed in recent years. Yet, even with the later acquisitions in the way of the Collarlette varieties, there is still room for the older favourites. It is sometimes alleged that they are not suitable for cutting for indoor decoration, but this may be traced to an improper way—or, rather, stage—of cutting the blooms for that purpose. Let them be taken from the plant when the buds are on the point of expanding, and it will be found that they will open quite naturally in water and last for quite a considerable time. Many of the single Dahlias are much more graceful than the Cactus varieties, and they have an equally wide range of colour, while, in addition, they bloom much more freely.—KIRK.

Dianthus hybridus "Cæsar's Mantle."—I think this is one of the most beautiful of the single hybrid pinks. The flowers are of such a brilliant crimson and are borne so freely that the plants make quite a vivid splash of colour in the rock garden. The flowers are borne on stiff stems, too, which is another point in its favour, and the whole habit of the plant is neat. It has not seeded with me, and it blooms so freely that it makes very few shoots for cuttings. I have found that the cuttings do not root quite so readily as those of most other Dianthus.—N. L.

Night-scented flowers.—In the cool of the evening the perfume of many flowers is accentuated, and, as many are debarred by business considerations during the day from enjoying the more brilliant flowering plants, those which are fragrant at night are doubly enjoyable. Among these may be mentioned *Nicotiana affinis*, *Lothian Stocks*, the white and coloured Pinks, *Schizopetalon Walkeri*, *Mignonette*, *Martynia fragrans*, *Matthiola bicornis*, *Heperis tristis* (the night-scented Rocket), the white *Campion*, and *Silene pendula*. It is a curious fact that nearly, if not quite, all of the scented flowers of the evening are white or pink in colour. Doubtless this and their perfume attract the insects which are abroad after dusk, and thus assist in the work of fertilisation.—KIRK.

The Martagon Lily.—This, I think, is a most accommodating Lily. It does not appear to be at all particular where it is planted, in shade or in sun, in a dry or a damp position. One of the finest clumps I ever saw was growing in Grass, and it certainly looked quite at home. The spikes were by actual measurement over 4 feet high, and I counted blooms to the number of seventeen on one of them.—K.

The Dittany of Crete (*Origanum Dictamnus*).—This, mentioned by "K. R. W." on page 294, does not appear to be nearly so plentiful as at one time. It is not so hardy as *O. hybridum*, which is quite as pretty. The pinkish Hop-like flowers, though small, are interesting.—S. ARNOTT

GARDEN PESTS AND FRIENDS.

SUMMER SPRAYS AGAINST AMERICAN GOOSEBERRY-MILDEW.

PROFESSOR B. T. P. BARKER, M.A., AND A. H. LEES, M.A., University of Bristol, have summarised in the present note the work on the summer treatment of American Gooseberry-mildew on which they have been engaged during the past two years. The results of this work, in the course of which liver of sulphur was used with varying effect, confirm generally the conclusion of Messrs. Eyre and Salmon which was given in the last number of this *Journal* (February, 1916) in an article on "A New Fungicide for Use Against American Gooseberry-Mildew." In that article an account is given of experiments conducted during the past two years on means of controlling the American gooseberry-mildew. Messrs. Eyre and Salmon conclude that "Solutions of liver of sulphur of the strength generally recommended for use as a fungicide are quite inefficient against the American Gooseberry-mildew: at a concentration at which the solution becomes fungicidal, such severe scorching injury is caused to the Gooseberry bush as to preclude its use." This conclusion is of considerable importance, since, as is pointed out, liver of sulphur has hitherto been considered by many investigators as efficacious against mildews in general and American Gooseberry-mildew in particular.

Trial has been made of a mixture which does not appear to have been previously used—a mixture of liver of sulphur and a soft-soap-and-paraffin emulsion, which has given most promising results. How far the liver of sulphur is the active fungicidal ingredient has not yet been determined. Probably each of the three constituents is required for full effect. In any case the preliminary results have been so satisfactory that it is desirable to test thoroughly the effect of liver of sulphur used in this way before finally rejecting this substance for the treatment of the mildew, especially in view of the frequent use of this substance as a fungicide, and its convenience and cheapness for this purpose. The primary object of this note is to call attention to this mixture, as used in the 1915 experiments, in the hope that it may be tried by other workers during the coming season and its actual value tested under a variety of conditions. The work was started at Long Ashton during the summer of 1914, in consequence of a slight outbreak of the disease in the plantations at the Research Station. It was decided to attempt to ascertain to what extent the disease could be controlled by summer spraying, the point of view taken being that if the summer stage of the disease could be adequately controlled the amount of the winter stage formed would be so limited that, with the further reduction of the latter by tipping, the outbreak the following season ought to be reduced eventually to insignificance. Details of the 1914 experiments having already been published,* only a short summary need be given here. The procedure adopted in the first set of experiments on the affected bushes was to apply, firstly, a spray which would kill by direct contact so far as possible the mycelium and conidia present on the bush, and, secondly, a protective spray to keep the parts on which the fungus had thus been killed free from infection from external sources. A number of fluids of the first type, i.e., "hitting" or "contact" sprays, was tested, including one composed of 4 lbs. of liver of sulphur and

20 lbs. of soft soap in 100 gallons of water. To each of the plots thus treated a series of protective or "cover" sprays, such as Bordeaux mixture, lime sulphur, etc., was applied. The applications were made at the end of July, the outbreak being a very late one. None of the results was entirely satisfactory, the mildew re-appearing fairly generally, although only slightly. In the course of this experiment it became evident that the "hitting" sprays were all more or less ineffective, because they failed to wet the fungus uniformly, owing to the presence of air between the conidiophores and the conidia. The importance of this point has also been emphasised in the paper by Messrs. Eyre and Salmon, who, owing to this difficulty, used their test fluids made up with 1 per cent. of soft soap. The writers, however, found that twice that quantity of soft soap did not suffice to give complete wetting, when the fluids were tested on a practical scale. Under those conditions liver of sulphur in the 0.4 per cent. solution mentioned above proved inefficient. Messrs. Eyre and Salmon found that it failed in soap solutions of half that strength, when the percentages of the sulphur compound used were about the amount stated. It is, therefore, probably correct to conclude that liver of sulphur used at the rate of 0.3 per cent. to 0.4 per cent. in aqueous solutions or in soft soap solutions is, at the most, of only limited value against mildews. (It is possible that a 1 per cent. solution might wet the less floury mildews, such as Pea-mildew, but fail with American Gooseberry-mildew.)

(To be concluded next week.)

NOTES AND REPLIES.

Grubs in Carrots.—I enclose two specimen Carrots from my bed of same this year. Will you kindly tell me if they are infested with Carrot-fly larvæ or wireworm? Hardly a plant has escaped in a bed about 8 feet by 40 feet, and I have had to destroy the lot.—EAST ANGLIAN.

[Your Carrots have been attacked by the grubs of the Carrot-fly (*Psila rosea*), a small black fly about $\frac{1}{4}$ inch across the wings. It appears in the spring and lays its eggs in the Carrots just below the surface of the ground. There are two or three broods during the summer. If the flies are noticed on or about the Carrots the latter should be sprayed with paraffin emulsion, or sand, wood-ashes, fine cinder-ashes, or sawdust should be soaked in paraffin and strewed between the drills with a view to keeping the flies away. Everything possible should be done to prevent the soil round the roots being disturbed so that the less the Carrots have to be thinned the better. The presence of the grubs is usually shown by the foliage turning yellow, and when this is noticed the roots should be examined, and those which are found to be attacked should be carefully removed, so as not to break them or leave any grubs in the soil.]

Destroying slugs.—I believe I have discovered a very effectual preventive against slugs. It is common rock salt, preferably broken in pieces about the size of a thumb-joint. I made experiments by surrounding some slug traps baited with bran with the salt and leaving others not surrounded. The traps that were not surrounded had plenty of slugs in and those that were surrounded had hardly any in. I have also tried various other experiments, which all go to show that slugs will not face this. The advantage is that in wet weather, when slugs are more active, the rock salt is not destroyed like lime and soot. I am not sure, of course, what effect salt would have if permanently left on the ground, but there is no need to do this, as it could be taken off when the plants were out of danger, and during that time the amount dissolved and entering the soil would be very small.—T. F. HAIGH.

* Annual Report of the University of Bristol Agricultural and Horticultural Research Station, 1914.

INDOOR PLANTS.

THE TASMANIAN LAUREL
(ANOPTERUS GLANDULOSUS).

This is a very handsome shrub, which, at least in most parts of the country, requires the protection of a greenhouse. In especially favoured districts, however, it is more or less hardy, with, in some cases, a certain amount of protection in winter. The specimen herewith illustrated comes from Nymans, Sussex, where so many presumably tender plants may be found flourishing in the open air. The handsome white blossoms are borne during the spring,

the growing season. These features should also be borne in mind in selecting for it a suitable sheltered spot out of doors.

W. T.

NOTES AND REPLIES.

Increasing Clematises.—Please let me know how to propagate Clematises—what kinds can be grown from seed?—C. H. B.

[The Clematis is readily propagated from cuttings. In doing so select a shoot with side growths that have flowered. Remove the side growths when a little more than half ripened. Insert closely together in a 6-inch pot, using a compost of loam, leaf-soil, and sand in equal pro-

over with a very little of the same. New growths will push up, roots be made, and the young plants can be severed after the shoots are 6 inches or so high. Of course, pay due care to ascertain whether roots are formed in sufficient number or not before removal. Clematises are also increased by grafting, but this we do not recommend. You will find an article dealing with the raising of Clematises from seed in our issue of March 27th, 1915, a copy of which can be had from the publisher post free for 1½d.]

Treatment of pink Spiræas.—Would you please tell me how to treat a pink Spiræa after flowering? Should it be kept in the green-

A flowering shoot of the Tasmanian Laurel (Anopterus glandulosus). From a photograph at Nymans, Sussex.

and the general aspect of a flowering shoot is well shown herewith. The leaves are of a firm, leathery texture, and of a rich deep green tint, while the blossoms are somewhat wax-like and remain fresh for a considerable time. It was introduced from Tasmania in 1823, and at one period used to be stocked by most nurserymen who made a speciality of New Holland plants. Now it is rarely met with. This Anopterus is not at all a difficult plant to propagate by cuttings of the half-ripened shoots, taken during the summer, inserted into pots of sandy soil, and kept in a close frame. Potted in a mixture of loam, peat, and sand, they will grow away freely, and, with reasonable drainage, require a liberal amount of water during

portions. Water well, and keep under a cloche or bell-glass until rooted. A temperature of 60 degs., with care to avoid any rapid rise beneath the glass from sun-heat, is most suitable. You can also use younger shoots, but these are more apt to damp off than those made as first recommended. Another method is by layering. Take a shoot at least three parts ripened, and lay this down in the ordinary way. Beneath each pair of eyes, or each second pair, make a "tongue" by cutting half-way through the growth, and slipping the knife up some inch or two towards the base of the eye or joint. In this, place a small piece of charcoal or sandstone to assist in keeping it open. Peg down upon a light compost of sandy loam, and cover

house growing on or dried off and later on repotted? I presume with good treatment it will flower again next year.—ELEANOR PAIN.

[The Spiræa should by no means be dried off till growth is complete and it goes naturally to rest. Presumably your specimen has just done flowering, in which case we should advise you to cut off the old spikes in order to prevent the development of seeds, which weaken the plant. Then it should be repotted (most likely a larger pot will be needed) in a mixture of loam and well-decayed manure, with, if the loam is very heavy, a dash of sand. The best place for it after that will be plunged out of doors in a sunny spot. A liberal amount of water is very essential, especially when the roots have taken

possession of the new soil. The pot, of course, must be well drained, but this should not be overdone. As autumn advances and the plant goes to rest it may either be allowed to remain plunged outside or taken into a cold frame. No doubt it will flower again next year, but whether the display will be equal to that of the present season is, to say the least, problematical. The year is now so far advanced that the period for growing and building up the crowns for next year's display is not a long one. We should not attempt to force it, as the flowers will develop much better when allowed to come on gradually. A good light position is very necessary to bring out the pink shade at its best.]

Injury to Aspidistra leaves.—Will you be so kind as to give the name, cause, and cure of this blight which has attacked my plant of Aspidistra?—ALICE M. BAMFORD.

[There is no blight or anything of that kind the matter with your Aspidistra. The brown spots look very much like the effects of the sun shining full on a leaf that has been generally shaded. If the leaf happened to be wet the damage would be more readily done. There are other possible causes, in proof of which we may mention that we were at one time consulted as to the presence of Aspidistra leaves going in the same way as yours have done. We saw the plants, and the position they occupied in a room where no gas was used, and were completely puzzled. Finally, after repeated investigations we learnt that the room was very little used in the evening. When necessary to go there a lighted candle was taken and usually stood on the same table as the Aspidistras. Occasionally the flame came too close to a leaf, and the damage was quickly done. Knowing all the conditions, it rests with you to discover the cause of the brown patches, which are certainly not due to any disease. It must be borne in mind that the Aspidistra is a shade-loving plant, but at the same time as much light as possible is beneficial.]

Hippeastrum Snowdon.—It is now a dozen years since this Hippeastrum was first shown, when it was given a first-class certificate by the Royal Horticultural Society. It was raised by Mr. C. R. Fielder when gardener to Mrs. Burns, North Mymms Park, Hatfield, and was obtained only after a long period of cross-breeding and selection. It must be regarded as one of the finest white-flowered Hippeastrums ever seen, an opinion freely expressed by those who saw the vase of flowers shown by Mrs. Burns at the meeting of the Royal Horticultural Society on June 6th. The flowers are large and of good shape, with just a suspicion of green in the centre. Every year the Hippeastrums become greater favourites. However much the generic name of Hippeastrum is used the old one of *Amaryllis* frequently crops up. This shows how difficult it is to eliminate an old-established name, which botanists, who are so fond of chopping and changing, might well bear in mind.—K. R. W.

Perpetual-flowering Carnations intended for flowering in winter are now well rooted, and the earliest batch will be top-dressed with Bentley's Carnation manure, and given alternate waterings of clear diluted soot-water. It is not advisable in this locality to pinch any of the flowering-spikes later than the first week in July. Staking is now being attended to, each shoot being carefully looped to the centre stake, and further tying will be attended to at regular intervals as the flowering-spikes develop. Malmaisons are now at their best. As the plants pass out of flower (if circumstances permit) layering will be carried out in a cool pit. The best of the one-year-old plants will be reserved for re-potting into larger pots for cultivation another season.—G.

GARDEN FOOD.

RASPBERRIES.

RASPBERRIES are, perhaps, the most delicious of fruits, but so dearly loved by the birds that it is difficult to secure a good supply. To secure the real flavour of the Raspberry it should be gathered the instant it is perfectly ripe, on a fine morning as soon as the dew has dried up. Look the fruits over carefully, for tiny grubs are fond of lurking in them, and place them in a glass bowl. Crush slightly with a silver spoon, sprinkle with caster sugar, and set aside in a cool larder for an hour. Another way of serving the fruit in a natural, uncooked method, is to take a pint of Red Currants and place in a basin. Sprinkle with a tablespoonful of caster sugar, and crush with a wooden spoon. Turn into a fine sieve, and allow the juice to strain over a quart of Raspberries which have been sprinkled with two tablespoonfuls of caster sugar. Chill slightly and eat with whipped cream.

RASPBERRY PIE is a pleasant way of cooking Raspberries. Butter a deep pie-dish rather thickly and cover the bottom with a layer of fine breadcrumbs. Next add a layer of Raspberries sprinkled with sugar; repeat alternate layers of Raspberries and crumbs until the pie-dish is full. The last layer should be of crumbs; sprinkle a little dissolved butter on top and bake in moderate oven for twenty minutes or until the top is nicely browned. Send to table either hot or cold.

RASPBERRY CUSTARD is rather an unusual way of serving Raspberries. Sprinkle some freshly-gathered Raspberries with a little caster sugar and stir well; place the fruit in a jar and stand in a warm oven until the juice commences to run. Strain through a sieve, and take a pint of the juice and mix very gradually with the well-beaten yolks of three eggs. If not sweet enough add a little more sugar, and turn the mixture into a jug, and stand this in boiling water. As soon as the Raspberry-juice and eggs thicken remove the jug and pour the mixture several times from one jug to another. When quite cold stir in two tablespoonfuls of cream. Half fill custard glasses with the preparation. Whip the whites of the eggs to a stiff froth, add sufficient sugar to taste, and a few drops of Lemon-juice; finally fold in two tablespoonfuls of stiffly-whipped cream. Fill the custard glasses with the whipped mixture and decorate with whole Raspberries.

Red Grod is a Danish dish made by mixing $\frac{1}{2}$ pint each of Raspberries, Red Currants, and Cherries, and simmering them with $\frac{1}{2}$ pint of water. Sweeten to taste, and stir in 3 oz. of ground Rice. Let the mixture simmer for twenty minutes, adding a little Red Currant juice if it becomes too thick. Pound 1 oz. of sweet Almonds, and add to the mixture. Finally stir in $\frac{1}{2}$ oz. of isinglass, and pour into a wetted mould. When cold, turn out and serve with thick cream around the dish.

H. T. C.

SOME RECIPES.

THE following recipes are sent us by Mrs. Philip Martineau, who is a student of the greatest of all reforms—food reform:—

STUFFED AND BRAISED CABBAGE.—Take one young Cabbage for each person. Remove a few outer leaves in order to thoroughly free the Cabbage from insects and slugs. Place a layer of sausage or other forcemeat between the leaves, which should be replaced and tied in. Slightly fry in a saucepan with butter or dripping till light brown; then season with pepper and salt. Place the lid on the saucepan and allow to cook slowly for an hour. Serve in its own brown gravy.

CABBAGE AU GRATIN.—Braise the Cabbage as in other recipe. When nearly cooked, place on a fireproof dish with a covering of breadcrumbs or powdered biscuit, a few bits of butter, and a slight sprinkling of Parmesan cheese. Set it in the oven or before the fire till the gratin is light brown, and serve in same dish.

CLEAR SOUP WITHOUT MEAT (FRENCH RECIPE).—Lightly fry in some good fat or butter to a good golden brown the following:—Two sliced Onions, two sliced Carrots, one Leek, one small Turnip cut up, one Parsnip cut up, small bouquet of Parsley and herbs; salt and pepper to taste. When fried, add 1 quart water; cover closely and simmer four hours after it has just come to the boil. Strain and serve either with freshly-cooked vegetables in dice, croutons of fried bread, or vermicelli. More water can be added if desired.

The Dandelion.—In America considerable attention is being paid to the cultivation of the Dandelion. It is used as a vegetable and for salads, and the roots are dried and sold for medicinal purposes. I find that the cultivated Dandelion is only pleasantly bitter, and if eaten when the leaves are quite young the centre rib of the leaf is not at all unpleasant to the taste. When older, the rib is tough and not nice to eat. I have not tried the Dandelion as a boiled vegetable, but eat it freely in salads, either alone or in combination with other saladings. It makes delicious sandwiches, the tender leaves being laid between slices of bread and butter, and sprinkled with salt. The addition of a little Lemon-juice and pepper varies the flavour. If the flower-buds are removed and the leaves carefully cut, the plant will last through the whole year. It can be blanched in the same way as Endive, and is then very delicate. If covered with an ordinary flower-pot during the winter and then buried under some rough stable litter the young leaves will sprout when there is a dearth of saladings and prove a welcome change in the early spring.—H. T. C.

Whole cereals.—Advocating the use of whole cereals as food in war time, Sir James Crichton-Browne, at a conference held recently by the Bread and Food Reform League, in the Queen's Hall, said that to some extent he was there as "a patriotic Scotsman" in defence of oatmeal. It was the most nutritious of the cereals, and certainly the most economical. Probably the people were better fed now in war time than in any previous period, but it was evident that cheaper foods would require to take the place of beef, eggs, and milk. Whole cereals would supply the necessary requirements, but it was essential that they should not be robbed of their principal constituents. Good digestion did not rest on appetite, but on mastication, and the prevalence of dental decay might be traced to the use of soft foods. He or someone whose voice is heard might well speak of the way this good food is spoiled by many cooks. It is reduced to an offensive pappy mess, whereas it may be cooked in an almost dry state—the right one. The larger oatmeal is served the better. I use the whole grain, which eats like Nuts and may be taken without milk or other adjunct if need be. It is called white groats in Scotland.—W.

Flavourings.—No allowance has been made in the Budget for any ready-made essences, sauces, or condiments. These things are as dear to the heart of the average English cook as they are abhorrent to the French one, and they account for much that is detestable in our national cookery. Not only will economy be effected but a great improvement in the *cuisine* will result if all flavourings are restricted to the ordinary garden herbs, including tarragon and chervil and the most usual culinary vegetables, and the simple natural spices and fruits of the earth.—*Patriotic Food Economy.*

TREES AND SHRUBS.

THE ROCK ROSES (CISTUS).

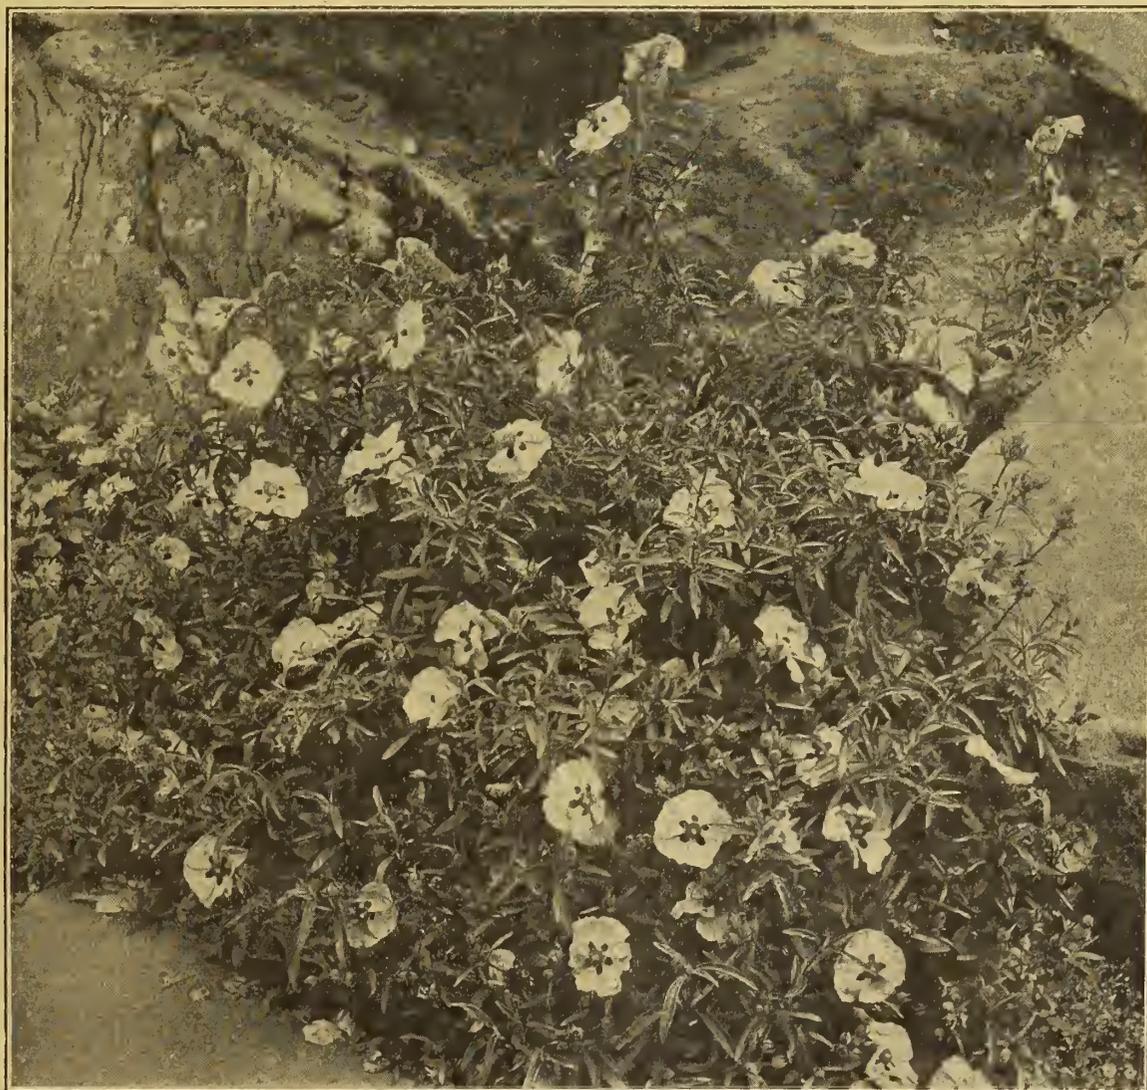

THE various species of *Cistus* or Rock Rose are amongst the most beautiful and free-flowering of summer-blooming shrubs, and the hardier ones should be planted wherever they can be grown. They are essentially sun-loving shrubs and are peculiarly well adapted for planting in prominent places in the rock garden or for covering bare banks with an exposure to south or west. As they are natives of South and South-West Europe and N. Africa many of them are tender, but there are others that withstand the severity of average winters in many parts of the

ground preparation required in forming a plantation is to remove all coarse weeds, dig the surface over, and insert the plants 2 feet to 3 feet apart, keeping the ground clean until the plants cover the space. During early life it may be advisable to remove the points of the shoots occasionally to induce a bushy habit, although the majority bear side branches freely without pruning. All later pruning is centred in the removal of flower-heads after the blooms are over. The majority can be increased by cuttings inserted in sandy soil in a close frame in July, but the species can also be easily raised from seeds sown in spring. Plants should be grown in pots until they can be planted permanently, for Rock Roses are difficult to transplant.

C. CORBARIENSIS forms a dwarf bush 1½ feet to 3 feet high, of dense habit, bearing white flowers over a period of two months in summer. It is one of the hardier hybrids, very free-flowering, and neat in habit.

C. CYPRIUS is less hardy than the previously-mentioned kinds, but it is a very beautiful plant, growing 6 feet or more high. It bears a profusion of white flowers, each petal marked at the base with a deep crimson blotch.

C. LADANIFERUS is very like the last-named, except that its flowers are borne singly, whereas those of *C. cypricus* are in small clusters. The flowers are, perhaps, a little larger, but each petal bears a simi-

Cistus purpureus in the rock garden at Friar Park.

country, and about London three or four species or hybrids withstood the severe winter of 1894-95 in the open ground. When, however, any doubt is entertained regarding the hardiness of any particular species it is a good plan to put in some cuttings during the summer, and winter them in a cold frame, or save a few seeds for spring sowing, then, if the parent plant is killed, stock is at hand and good-sized flowering specimens may be had in the course of a year or two.

Rock Roses do not need rich soil; in fact, plants grown upon poor loam or sandy gravel often give better results than those planted in good ground, for growth is arrested earlier in autumn and the wood becomes better ripened. As a rule, the only

A great many species and varieties are known, but the following will be sufficient for most gardens. The hardiest of all is

C. LAURIFOLIUS, which grows 6 feet or more high and bears during June and July large inflorescences of white flowers, each nearly 3 inches across.

C. LORETI is another very free-flowering, hardy sort. Its parents are said to be *C. ladaniferus* and *C. monspeliensis*. It grows into a dense, shapely bush 3 feet to 4 feet high, with ample dark green leafage. The flowers are each about 2½ inches across, white, with a crimson blotch at the base of each petal, several flowers appearing together in loose clusters. Where but one *Cistus* is wanted this should be selected.

lar blood-red or crimson blotch. It is not quite so hardy as *C. cypricus*.

C. PURPUREUS, the subject of our illustration, is one of the most beautiful of all Rock Roses. Forming a bush at least 4 feet high, it bears handsome dark green leaves and wonderfully pretty flowers, each 3 inches across, the colour a very pleasing shade of reddish-purple with a dark crimson blotch at the base of each petal. Although it is not very hardy, it thrives in many places, notably in Sir Frank Crisp's garden at Friar Park and in Miss Willmott's garden at Warley Place.

C. VILLOSUS, also rather tender, has greyish leaves and rose-coloured flowers.

C. MONSPELIENSIS grows from 1½ feet to

3 feet high and forms a dense bush, the flowers white and borne freely during June and July.

C. ALBIDUS and C. FLORENTINUS are two other white-flowered sorts of moderate growth, while the rather tender C. crispus is conspicuous by reason of its greyish leaves and light red flowers. D.

Moving a Laurel hedge.—Is it possible to move safely into an adjoining trench a well-grown Laurel hedge? We are having much rain.—BUTLER, *New Forest*.

[You cannot with safety lift and transplant Laurels at this season of the year. Better wait until November next, when there would be no risk whatever attending their removal.]

Magnolia macrophylla.—A few years ago a very fine plant of this handsome Magnolia was to be seen in Messrs. Veitch's nursery at Coombe Wood, where, during the summer, it was a very conspicuous object by reason of its large leaves and fine flowers. An even finer tree and, perhaps, the best in the British Isles grows in H.R.H. the Duchess of Albany's garden at Claremont. Three or four years ago that tree was nearly 40 feet high, with a good-sized trunk, and it flowers well every year. *M. macrophylla* is a native of the south-eastern United States, and was introduced to European gardens over 100 years ago. Its rareness at the present time is doubtless due to its being rather fastidious regarding soil and position, and by its being tender in a young state, more especially when growth is very rapid. The leaves often each measure between 1½ feet and 2 feet in length and 9 inches in width, the length being sometimes exceeded by a foot and the width by 3 inches or 4 inches. The cream-coloured or buff, fragrant flowers, each often between 9 inches and 12 inches across, are produced during summer, usually after the leaves are fully grown. Altogether it forms a most striking and beautiful object in the milder parts of the country. It should be planted in a position sheltered from rough winds in light, loamy soil fairly free from lime and containing leaf-mould or a little peat. It is usually propagated by imported seeds.—D.

"Witch's Broom" on the Willow.—This curious growth, which is caused by the insect *Eriophyes triradiatus*, is unfortunately more plentiful this season than ever. In the London area Willow-trees suffering severely from repeated attacks are to be found, and nowhere probably is it more plentiful than in some of the larger parks and on Hampstead Heath, where hardly a tree has escaped. Willow-trees that were quite free from the insect last season are now seriously damaged, and two at least of those on which the growths appeared nine years ago have succumbed to the annual attacks. With the exception of the Goat Willow (*Salix caprea*), most others, both species and hybrids, are attacked, and not only in the metropolitan area but far into the country as well. Spraying with several kinds of insecticides has done little good, but pruning off and burning all attacked shoots in the autumn have been followed by good results. This is difficult, especially in the case of large trees, but at present it is the only known way of keeping the insect in check and is to be recommended.—A. D. WEBSTER in *Gardeners' Chronicle*.

Abutilon vitifolium in Scotland.—This, in a few places in the south-west of Scotland, is quite a success. Probably the finest specimen in the south-west of Scotland is that at Logan, Wigtownshire. That on the wall of the old garden at Monreith is probably the next in point of size and health. The latter stands the winter and flowers annually.—S. ARNOTT.

FRUIT.

GRAPE CULTURE.

THERE is much truth in the article dealing with the culture of Grapes which appeared in the issue of June 17th. In many instances, as "Byfleet" says, a gardener achieves a reputation as a champion Grape grower. He maintains this reputation for a few seasons and then vanishes into obscurity. "Byfleet" is correct in assuming that, in the majority of cases, this is due to the early vigour of the Vines having become less, their constitution weaker, and that, consequently, the bunches are no longer up to exhibition form. There is, however, no reason why Vines of considerable age should not, given proper treatment, produce bunches which will hold their own in any company. There is a case in point in the neighbouring county of Wigtown. I refer to the Vines in Sir Herbert Maxwell's well-known gardens at Monreith. To my knowledge these canes must be close upon forty years of age; at any rate, well over thirty. Even in their early stages they were somewhat heavily cropped, and it was a subject of comment at exhibitions that these rods would soon collapse unless they were eased up. What are the facts? Scottish exhibitors will unanimously agree that Mr. Gordon, Sir Herbert's gardener, is a formidable man to meet in competition at our principal Scottish shows. If my memory serves me rightly, in September, 1913, Mr. Gordon took the premier place for a collection of Grapes at the Royal Caledonian Society's Exhibition in Edinburgh. This feat he again repeated in 1915, and, in addition, he took the leading awards for bunches of separate varieties—no mean feat at an Edinburgh show. His last achievement was admitted upon all hands to be thoroughly deserved, and a verdict such as that from the Waverley Market critics speaks for itself. Mrs. Pince, occasionally difficult to finish, was shown magnificently, Black Hamburg was almost as fine, Madresfield Court was never staged better, and Muscat of Alexandria was noteworthy. Nobody will class Alnwick Seedling as being equal to these varieties in flavour, but as a specimen bunch it was, perhaps, the best in the show. I have referred at some length to this particular case, but I know of other gardens in which similar, if not quite such striking, results have been attained by bunches from Vines which might have been judged to be past their prime, judged by the years which have elapsed since they were planted. The whole question resolves itself into the close and intimate personal supervision which the grower gives to his Vines, to his knowledge of the requirements of each variety, and to strict and unceasing vigilance to detail. The man who is not prepared to sacrifice his own convenience, and, at times, his leisure hours, will never be a successful grower or exhibitor of Grapes, and it is easier by constant attention to maintain Vines in a high state of bearing than to restore that condition when the canes have been, even for a season, comparatively neglected. W. MCGUFFOG.

Balmoe Gardens, Kirkcudbright.

NOTES AND REPLIES.

Peach-tree leaves falling.—Kindly tell me what is wrong with a Peach-tree I have (indoors)? You will see by the enclosed that the leaves are affected, and fall freely. It is a Dr. Hogg. A Princess of Wales next to it and in the same border is quite healthy.—W. T. DEEKS.

[The leaves of the Peach-tree in question appear to us to be infested with

"Leaf Rust," which attacks the foliage of several other species of fruit-tree also. The effect of an attack is to cause a premature fall of the leaf, which corresponds exactly with what you mention in your note. These fallen leaves should be gathered up and burnt, and the whole of the tree sprayed at once with liver of sulphur, dissolving 1 oz. in 3 gallons of warm water in which 3 oz. of soft soap have been previously dissolved. Another season spray the young leaves after the tree has flowered, and set its fruit with ½ oz. solution of the same chemical. As the leaves develop and become firmer and less susceptible to harm increase the strength to 1 oz. per 4 gallons of warm water. Spray at fortnightly intervals, from three to five sprayings being necessary.]

Treatment of Vine.—Owing to alterations, my Vine in cold-house has been moved. The Grapes are ruined for this year. It is making long, inconvenient growths. May I cut them, leaving, of course, the few bunches showing?—BUTLER, *New Forest*.

[The laterals on the Vine in question would be the better for being shortened back to the seventh or eighth leaf—counting from the rod—as it will strengthen the buds at the base of these growths, which, when spurred back in due course in winter and started again next year, will produce infinitely better bunches than if they are left unstopped now.]

Peach Early Grosse Mignonne.—In this we have a variety which is not only early, but which carries fine, handsome fruits as well. These, in addition, are well coloured if a little attention is given to exposing them to the sun by removing obtrusive foliage. *Grosse Mignonne* makes an excellent succession to *Hale's Early*, also a good and early Peach. Even when the former is somewhat sharply forced, the flavour is first-rate. A vigorous grower, over-luxuriance has to be guarded against, for overcrowding is distinctly against the proper maturation of the wood. Firm planting will, of course, do something to check gross wood, although it is noteworthy that *Grosse Mignonne* will fruit upon much stronger and coarser wood than, for example, *Waterloo*. I have noticed the same thing in *Violet Hative* and one or two others of the early Peaches.—KIRK.

Figs.—Trees which are developing the second crop of fruit must be treated to liberal supplies of diluted liquid-manure, and the mulch, if that last applied has with frequent waterings become deprived of any further nutritive properties, should as far as possible be removed and fresh material substituted for it. All this is necessary if the fruits are to attain any size. A humid atmosphere must be maintained until the fruits begin to ripen, and the trees, except when the flowering period is reached, be vigorously syringed morning and afternoon. If closing is done early enough to secure a temperature of 90 degs. little, if any, fireheat is required at night now.—G. P. K.

Pear Louise Bonne of Jersey.—There is this year a full crop of this very fine Pear. In our northern latitude *Louise Bonne* must be given a wall, and, generally speaking, the variety is among the surest croppers. It seems to require double grafting, for if on the Quince it is rather shy in respect of growth, and in unfavourable years the fruits are apt to crack. As regards flavour, there are few who do not appreciate a thoroughly ripe *Louise Bonne* with its vinous flavour and crisp flesh.—W. MCG.

Apricots.—Stoning is now sufficiently advanced for the final thinning to be done. Although more fruits may be left in a given area than is usual with Peaches, this rule should not be carried to the extreme, as is sometimes seen, as the energies of the trees are then overtaxed and their cropping powers crippled for the next season or two. Unless the soil next the wall is found on testing to be really moist, the alley portion of the border should receive a good soaking of water directly thinning is finished.

ROOM AND WINDOW.

CLEMATIS FOR THE HOUSE.

Among the good qualities of the hardy Clematises one of the very best is their value for the house. Where freely grown, as they should be in every good garden, it is a pleasure to see the long, graceful shoots when cut—the firmer they are the longer they will keep, depending from mantelpieces, tables, and vases with a charming grace. Most of the species and varieties are useful in this way, and their season of bloom lasts as long as from May until the autumn. The one here shown I have used for years with great success for its effect in the garden and the house.

Sprays of Clematis Perle d'Azur in a jar.

It is on its own roots, *i.e.*, not grafted in the usual trade way, and produces thousands of flowers every year. W.

Green insects on various plants (F. T.).—The little green insects which you found in the little masses of froth on various plants are immature specimens of the common Frog-hopper (*Aphrophora spumaria*), a small dark brown insect, which springs away when disturbed in a very rapid manner. When in its immature state it injures the plants which it attacks to a considerable extent, for not only does it draw from the plant enough of its juice to feed itself, but also to form the froth covering with which it is surrounded. The best way of destroying this insect is to take a cup of water and a small stiff brush—an ordinary gum brush does very well—remove the insect with the brush, and wash the brush clean in the cup.

VEGETABLES.

REMOVING ARTICHOKEs.

WHAT would be the best time to remove Globe Artichokes (large plants); also Jerusalem Artichokes and Seakale plants (that have not been forced and are about three years old); also strong plants of Thyme about two years old?—ANON.

[Globe Artichokes are best lifted and transplanted in spring, say, the end of March or early in April, according to the weather. As the plants or stools, as they are termed, are large they should be divided, leaving from two to three suckers or young growths on each division. Plant on deeply-worked, well-

length of root attached to them, can then be forced and afterwards thrown away, as they would be of little or no further use. The cuttings, if planted on well-manured ground, and supplied with stimulants during the growing season, will, or should, make very fine crowns by the end of the season. If required to be lifted for forcing they should be set out in rows 18 inches apart, and if space is available allow the same distance between the sets. Plant the cuttings with their tops or upper portions level with the soil, and cover each afterwards with a handful of fine cinder ashes. When they commence to grow remove all but one shoot on each set, leaving as a matter of course the strongest. If the Seakale is required for a late supply, and the blanching is to be done either with pots or by means of fine soil or ashes formed into mounds over the crowns, then plant the cuttings in groups of three, triangular-wise, and 9 inches apart, allowing a distance of 3 feet between the groups. The rows in this case should be 4 feet apart, which provides space for the disposal of the ashes or soil when not in use.

The Thyme roots may be transplanted either in autumn or spring, whichever may be the more convenient. When sending queries please sign each one.]

HOLLAND HOUSE SHOW.

JULY 4TH, 5TH, AND 6TH.

ALPINES.

THE greater wealth of alpine plants is not usually reserved for this show, and this year fewer collections were forthcoming.

Mr. Reginald Prichard, West Moors, Wimborne, had, however, some good novelties, more particularly *Cyananthus incanus leicalyx*, a novelty of distinctive if not attractive shade, *Campanula Kolenatiana* and *Silene Prichardi*, hybrids from *S. Hookeri* and *S. virginica* which have a colour range in salmon and scarlet. In the group from

Mr. J. Box, Lindfield, Sussex, outstanding subjects were *Ourisia coccinea* (scarlet tubular flowers) and *Anemone demissa*, which bears handsome clusters of bluish-white flowers on foot-long pubescent stems. It is obviously a plant of merit. Messrs. T. S. Ware, Limited, Feltham, J. Cheal and Sons, Crawley, and Pulham and Son, Eelsenham, had extensive collections of alpines rich in Thymes, *Dianthi*, Cobweb Houseleeks, and other plants. Messrs. Whitelegg and Page, Chislehurst, also had many good things, their notables, the lovely blue and white *Campanula garganica* W. H. Paine and *C. pusilla* Miss Willmott, whose silvery pale blue bells appeal to all.

Mr. Clarence Elliott, Stevenage, sheeted a rock bank with *Campanulas* Miss Willmott, *cenisia*, *pulla*, *pulloidis*, and *G. F. Wilson* among others, arranging them in informal colonies to represent the established article in the garden. *Campanula Raddeana* was also shown, its lax habit, taller growth, and distinctive bells quite an attraction. *Thymus Serpyllum coccineus*, *Saxifraga aizoides atrorubens*, *Pink Firefly*, and *Pink Octavius Ferry* (rosy-crimson, maroon centre) afforded a touch of brightness to a pleasing whole.

Mr. G. Reuthe, Keston, Kent, had some lovely patches of hardy Heaths, the most brilliant of which was *Erica cinerea pygmaea*. *Rhododendron daphnoides*, an alpine bush of 15 inches high, was smothered with pale pink flowers, and quite a gem in its way. *Ononis fruticosa* (rosy-scarlet), *Saxifraga squarrosa*, *Campanula Raddeana*, and *Polygonum*

manured ground in rows 4 feet asunder, and allow the same distance between the plants. Jerusalem Artichokes should not be lifted until the tubers are mature—*i.e.*, either in late autumn or during the winter. Planting in a fresh site may be done during March—using medium-sized, well-shaped tubers for the purpose, and in rows 3 feet apart and 1 foot between the sets. The three-year-old Seakale plants will not pay to transplant. The best way to deal with them would be to lift the crowns in November, saving all the strong, thong-like roots that will be found attached to them, and making them into cuttings some 7 inches or 8 inches in length, cutting the top part flat and the lower ends in a sloping direction to serve as a guide when planting in March next. The crowns, with a certain amount and

sphaerostachyum were all attractive and good.

Prominent items in a group from

Mr. Maurice Prichard, Christchurch, were *Campanula mirabilis*, a rare species seldom seen, *C. arvensis*, a lovely miniature, and the brilliant hybrid *Geranium Russell Prichard*. *Orchis foliosa*, *Genista tinctoria humifusa*, and *Alstroemeria revoluta*, of rich red tone, were others of merit and importance.

SWEET PEAS.

QUITE a notable lot came from Messrs. Alex Dickson and Sons, Newtownards, their new orange-scarlet variety *John Porter* being given an Award of Merit. *Hawmark* (cream), *May Unwin*, *Blue Picotee*, *Melba*, *Royal Purple*, and *Phyllis* were others in a particularly good lot. Excellent flowers, too, were shown by

Messrs. S. Bide and Sons, Farnham, such as *Constance Hinton* (purest white) and *Fiery Cross* affording a sharp colour contrast. *Golden Glory*, *Edward Cowdy* (orange-scarlet), and the handsome deep mauve *Queen of Norway* were a few that appealed strongly.

Messrs. E. W. King and Co., Coggeshall, arranged a central column with pillars of smaller size disposed around, linked together, as it were, by trails of *Asparagus*. The arrangement was effective. The firm's notable varieties, *Anglian Crimson*, *Anglian Orange*, *Anglian White*, and *Anglian Fairy*, were noteworthy. Messrs. R. Sydenham, Limited, Birmingham, and J. Piper and Sons, Bayswater, also had large collections.

ROSES.

Some eighteen exhibitors showed collections of these, either alone or in conjunction with other flowering plants, the leading growers being well to the front. To three of these gold medals were awarded. Messrs. Alex Dickson and Sons, Newtownards, Ireland, arranged their superb lot adjoining their collection of Sweet Peas, and rarely have they shown better in either section. We regarded *Margaret Dickson Hamill* (rich golden-yellow), *Donald MacDonal* (reddish-scarlet), *Red Letter Day*, *Christie MacKellar*, and *Mrs. W. Quinn* as among the finer sorts staged. Mr. Elisha J. Hicks, Twyford, displayed on pillars and arches and in other ways some of his leading novelties. In this way the single crimson *Princess Mary* afforded a brilliant mass of colour, the creamy semi-double *Joanna Bridge* (very fragrant) being in sharp contrast. The new *Pink*, *Chas. E. Shea*, one of the two "gold medal" roses at the National Rose Show, was in strong force, together with a wealth of other sorts. Mr. Chas. Turner, Slough, arranged a particularly effective group, in which pillars of *Wichuraiana* and weeping standards dowered with blossoms made an imposing picture above the wealth and variety seen in stands and epergnes.

Messrs. Wm. Paul and Son, Waltham, also had an imposing display, making much of their new pillar *Rose*, *Scarlet Climber*. *Goldfinch* was also most effective, whilst masses of *Ophelia*, *General MacArthur*, and *Queen of Fragrance* entered freely into the arrangement.

Messrs. Paul and Son, Cheshunt, also showed magnificent blooms; indeed, we considered these the *élite* of the whole exhibition. Their stands of *Lemon Pillar* and *Mme. Edouard Herriot* were grand, and surely nothing finer in pillar *Roses* than the first-named could be desired. *Rosa lucens The Premier* (*lucens* x *Mrs. A. R. Waddel*) was beautiful among white cluster *Roses*. *Naiad* (Hybrid Briar) opens out its big cream-white blossoms

Magnolia fashion, and, with gold anthers and red filaments, constitutes a picture of rare beauty. The finest thing in a group from

Messrs. W. and J. Brown, Peterborough, was the arches of their new single *Mrs. Rosalie Wrench*, a semi-double of a most attractive shade of rose-pink.

Messrs. H. Cannell and Sons, Eynsford, Kent, also showed a collection in which *Lyon*, *Sunburst*, *Rayon d'Or*, *Molly Sherman Crawford*, *General MacArthur*, *Mme. Melaine Soupert*, *Mme. Jean Dupuy*, and *Sweet Lavender* were excellent.

Messrs. B. R. Cant and Son, Colchester, contributed fine stands of the yellow *Iona Herdman*, together with *Sallie* and *Cupid*, varieties to which we have previously directed attention. In a group from Mr. George Prince the white semi-double *Una* was very good; also *Seagull* and *Goldfinch* among free-flowering cluster *Roses*. Messrs. Stuart Low and Co., Enfield, had in vases and epergnes many of the finer *Roses*, as *Lady Pirrie*, *Lyon*, *Mme. Edouard Herriot*, and *Juliet*. In Messrs. Chaplin Bros.' group from Waltham Cross we thought the new white *Mrs. A. W. Atkinson* the finer and more distinct. In that from Mr. Walter Eastlea, Eastwood, the fragrant flesh-pink and white full double novelty *Dr. Joseph Drew* attracted attention; Messrs. F. Cant and Co. making a good display of *Mrs. C. E. Salmon*, *Vivid*, *Blush Queen*, and others. *Edward Mawley*, *Rayon d'Or*, *Marquis de Sinety*, and *General MacArthur* were some of the best in a fine assortment from Messrs. G. Jackman and Son, Woking.

CARNATIONS.

Mr. James Douglas, Great Bookham, was alone in showing border varieties, the stand also including a few varieties of *Pinks*. The crimson-flowered *Hercules* was very fine.

Messrs. W. Cutbush and Sons, Highgate, N., made an imposing display of their new scarlet perpetual-flowering *Malmaison Sabina*, while such as *Enchantress Supreme*, *Marmion* (scarlet and white), and *White Wonder* afforded variety. In the group from

Messrs. Stuart Low and Co., Enfield, the new white-flowered *Malmaison Charles Blick* was quite a feature, the blooms large and of excellent quality. *Princess of Wales*, *Mrs. Myles Kennedy*, and *Countess of Wilton* were some others in the group. Mr. A. F. Dutton, Iver, Bucks, showed a general collection of perpetual-flowering sorts, *Louvain* and *Lady Meyer*, among others, being remarked, while conspicuous in a group from Mr. Chas. Turner, Slough, were many handsome flowers of the *Malmaison Princess of Wales*. Messrs. Laxton Brothers, Bedford, showed a dozen or so handsome vases of their new salmon-pink flowered *Bedford Belle*, which, while richly coloured, is also very free-flowering and sweetly scented.

BEGONIAS.

Messrs. Blackmore and Langdon, Bath, had the finer display of these, the new double orange-scarlet *Mrs. C. F. Langdon* standing out well from the rest. Other good sorts were *Chrystabel Spry* (salmon) and *White Venus*.

Messrs. T. S. Ware, Ltd., Feltham, and J. Peed and Sons, West Norwood, S.E., also contributed of their fine strains of these valuable greenhouse subjects.

STOVE AND GREENHOUSE PLANTS.

The most extensive collection of these was that from Mr. L. R. Russell, Richmond, whose examples were chiefly of specimen size and particularly well grown.

A well-flowered example of the rarely seen *Medinilla magnifica*, whose pendent racemes of pink always attract, was among good things, while bright-coloured examples of *Dracena Victoria*, well-developed *Alocasias*, and much more assisted in the display. *Gloriosa Rothschildiana*, in flower, was very telling, while many well-fruited examples of *Nertera depressa* also played a part.

Messrs. J. Peed and Son, West Norwood, S.E., showed a particularly good bank of their unrivalled *Caladiums* margined with *Streptocarpus* in variety.

Messrs. R. and G. Cuthbert, Southgate, N., had a most attractive group of *Streptocarpus* and *Gloxinias*, both families containing many fine varieties. In the first named *Rose Queen* and *Southgate White* received Awards of Merit, both being great advances upon existing varieties. The strain generally was of high excellence.

Messrs. W. Cutbush and Sons, Highgate, N., in a miscellaneous group showed the new Ivy-leaved *Pelargonium Radiance* well. It is particularly effective in colour and a great bloomer. Messrs. Godfrey and Sons, Exmouth, Devon, had a large group of *Regal* and *Fancy Pelargoniums*. Messrs. J. Piper and Sons contributed an interesting lot of *Cacti*. *Zonal Pelargoniums* were shown by Messrs. Jarman and Co., Chard, and Mr. Vincent Slade, Taunton.

TREES AND SHRUBS.

In this section the exhibit in the open from the Donard Nursery Co., Newcastle, Co. Down, Ireland, was that most replete of interest and novelty. In this connection the newer *Leptospermums* held pride of place, the rich red of *Nicholli*, the larger if paler flowered *Chapmani*, and the quite new *Donard Beauty*, a rosy-crimson form of the first and which obtained an Award of Merit, being conspicuous. Another plant of importance, *Escallonia Donard Seedling*, also gained an Award of Merit. It is a hybrid between *E. Langleyensis* and *E. Philippiana* having starry, pinky-white blossoms profusely borne upon a bushy-habited, glossy-leaved plant. *Rosa Moyesi*, *Spirea Henryi* (a white-flowered species), and a series of *Olearias*, which included *O. chathamica*, *O. semi-dentata*, and *O. ilicifolia*, were also on view among much else of merit and interest.

Mr. J. C. Allgrove, Middle Green, Langley, Slough, displayed at one end of a most interesting series of hardy plants some well-flowered branches of the golden-cupped *Fremontia californica* and the white crimson-centred *Magnolia parviflora* backed by a mass of *Philadelphus Virginal*, the purest and best of its tribe. *Rosa Moyesi* gave a brilliant display of its coppery-crimson flowers.

Messrs. J. Watqer, Sons, and Crisp, Bagshot, had a fine group of *Kalmia latifolia*, with an edging of *Eurya latifolia*.

Mr. L. R. Russell, Richmond, contributed freely of *Ivies*, *Escallonias*, *Clematis* in variety, species of *Vitis*. A group from Messrs. Piper included several species of *Viburnums*, also *Rubus Veitchi* and *Giraldiana*. In that from Messrs. J. Cheal and Sons, Crawley, *Escallonias* occupied some prominence, together with *Veronicas*, *Philadelphus*, and much else in season. Dwarfed Japanese trees were shown by Messrs. Barr, Covent Garden, and the *Yokohama Nursery Company*, Kingsway.

HARDY AND GREENHOUSE FERNS.

A great bank wholly of hardy Ferns and in well-grown specimens for the most part came from Mr. Amos Perry, Enfield, the collection rich in the plumose forms of *Polystichum* and containing very fine ex-

amples of *Athyrium*. *Scolopendrium crispum nobile* was grand.

Messrs. H. B. May and Sons, Edmon- ton, had a most effective and tastefully- arranged group of Ferns, hardy and exotic, the former very rich in the crested and tasselled Hart's Tongues and plumose and crested *Athyriums* among many others. Among tender sorts the red-tinted *Adiantum Veitchi* was very beautiful; not less striking the all too rarely seen *Pteris tricolor*, which was in excellent health. Silver and gold *Gymnogrammas*, with *Lycopodiums* and *Selaginellas*, assisted in making a very interesting whole.

ORCHIDS.

These were not seen on so grand a scale as usual, though good novelties were fairly plentiful. In Messrs. Charles- worth's group a big centre was formed of the finer *Miltonias*, *Odontioda Chanticleer* (brilliant scarlet) and *O. Brewi callisto- glossa* (glossy maroon, golden crest) being very striking.

Sir Jeremiah Colman, Bart, Reigate, had the rare *Sarcochilus Cecilie* with pink flowers on 6-inch-high sprays, *Cattleya Warscewiczii* King Edward VII., and *Nanodes Medusæ*, the fringed flowers of crimson-maroon very striking. *Disa Luna* (rose-coloured) was very good in a group, and there were some choice *Lælio- Cattleyas*.

Messrs. Sander and Sons, St. Albans, showed *Cirrhopetalum robustum*, *Anguloas*, *Miltonia Isabel* Sander Brilliant, *M. Hyeana Colossus*, and *Cattleya Warscewiczii Sanderiana* were very bright and good, the new *Odontioda General Brussio- loff* of exceptional colour richness.

Messrs. Stuart Low and Co., Enfield, had a big lot of *Cattleya Warscewiczii*, together with *Phalenopsis Rimestadiana* and *Renanthera Imschootiana*. *Cattleya Warneri alba*, some fine *Lælio-Cattleyas*, and *Odontoglossum Lambeauianum* were also remarked.

Messrs. Mansel and Hatcher, Rawdon, Yorks, showed *Miltonia vexillaria Virginal*, *Lælio-Cattleya Aphrodite* (a very hand- some batch), *L.-C. Cora*, and the white *Phalenopsis Rimestadiana* among many others. The outstanding subject in a group from Messrs. J. and A. MacBean, Cooksbridge, was *Odontoglossum Hye de Crom*, one form of which, in maroon and gold, was very telling. *Odontoglossum Leviathan* was noteworthy.

Messrs. Armstrong and Brown, Tun- bridge Wells, had a few of the choicest kinds, most prominent being the new *Miltonia J. Gurney Fowler* (white, rose- tinted, darkest maroon centre, and much the largest yet raised). *Cattleya Mendelli* (new white form) was very chaste and beautiful. *Odontioda Seymouræ* (almost vermilion), *O. Joan* (crimson-red), and *O. Henryi* (a blend of apricot and terra-cotta, with yellow crest, having the handsome spike and proportions of the best *Odonto- glossum crispum*) were much admired.

NATIONAL SWEET PEA SOCIETY.

JULY 11TH, 1916.

The sixteenth annual exhibition, held in the Royal Horticultural Hall on the above- named date, must, from every point of view, be accounted a great success. True, we have seen the hall fuller of flowers, but we remember no exhibition equal to that under review, judged by the quality of the flowers, with which, naturally, are incorporated refinement and the reduction to a minimum of that grossness which in the past, in leaf as in flower, has robbed the Sweet Pea of not a little of its grace and charm. Hence to-day, while we re-

gard this year's display favourably from the quality standpoint, we think it also makes for progress in the direction indi- cated. To bring out all that is best in a flower, be it what it may, is one of the aims both of exhibitions and exhibitors; to do so while retaining its chief charac- teristics represents the highest cultural skill. That is the stage which we consider the best Sweet Pea cultivators have reached at the present time, a stage which, while clearly indicating that the grower is learning more about his subject, also shows that such knowledge is being put to the best use. Leaves like Coleworts and much flower grossness have in the past found their way into this important show; in that recently held they were con- spicuous by their absence.

Here and there were seen a few vacant places for which, doubtless, the recent severe storms, sunless days, and cold nights were largely responsible. This notwith- standing, there was considerable competi- tion in all the leading classes and a show of which any society might feel justly proud. For the flower the day approached the ideal, and if fuller sunlight would have added great brilliance to the whole, its absence so assisted lasting properties that the flowers were as perfectly fresh at the close of the day as when first set up. Moreover, the visitors were enabled to enjoy the feast at leisure. To-day we have to regret that exigencies of space and other matters over which we have no control preclude our giving a detailed report of so good a show, hence the briefest references thereto must suffice.

The Henry Eckford Challenge Cup this year goes to Shrewsbury, Mr. W. H. Hollo- way being the winner. The Sutton Cup for eight varieties was won by Mr. H. H. Lees, Polsloe Road, Exeter, who showed admirably. The John King Challenge Cup also goes to Shrewsbury, Mr. W. Philip Astley being the winner. In the leading classification class Mr. Henry D. Tigwell, Greenford, Middlesex, won with a superb lot. The seedling class for three bunches distinct not yet in commerce brought but one exhibitor, Mr. J. Stevenson, Wim- borne, whose Faith (sky-blue and mauve) and Royalty (reddish-purple) were good.

Mr. E. W. Broad, Trezinger, Fowey, secured the E. W. King Challenge Cup with a handsome lot of flowers, the Burpee Cup for a display of waved Sweet Peas on a space 8 feet by 3 feet worthily falling to Mr. E. G. Mocatta, Woburn Place, Addlestone (gardener, Mr. T. Stevenson), for a most artistic arrange- ment. Thirty vases were set up, each dis- played to advantage; an object lesson in skilful work. In the special division (amateurs) for the new Hawlmark Chal- lenge Cup Mr. Thos. Jones, Ruabon, was an easy first, his flowers good and well staged.

NON-COMPETITIVE EXHIBITS.

These were in strong force and materi- ally assisted the show from the spectacular standpoint as well as affording evidences of skilful arrangement. Gold medals were awarded Messrs. Dobbie and Co., Edin- burgh, Mr. J. Stevenson, Wimborne, Messrs. Alex Dickson and Sons, Belfast, Messrs. E. W. King and Co., Coggeshall, Messrs. Piper and Son, Bayswater, and Mr. Robert Bolton, Warton, Carnforth, for collections of the highest merit and excel- lence.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM JULY 12TH.—*Androsace lanuginosa*, *Ethionema coridifolium*, *E. grandiflorum*, *Campanulas* (in great variety), *Potentillas* (in variety), *Sedums* (in variety), *Sempervivums* (in variety), *Aubrietias*, *Dianthus* (in variety), *Ourisia coccinea*, *Delphinium nudicaule*, *Veronicas* (herbaceous and shrubby) (in great variety), *Santolina viridis*, *S. alpina*, *Omphalodes cappadocica*, *Primula Bulleyana*, *P. Cockburniana*, *P. capitata*, *Onosma tauricum*, *Lithospermums* (in variety), *Convolvulus Cneorum*, *C. mauritanicus*, *C. sylvaticus incarnatus*, *Erodiums*, *Gypsophilas*, *Meconopsis*, *Thymes* (in variety), *Glossocomia clematidea*, *Orchis foliosa*, *Cypripedium spectabile*, *Vinca minor variegata*, *Heucheras* (in variety), *Helianthemums*, *Cistus* (in great variety), *Geums* (in variety), *Aquilegias* (in variety), *Linarias*, *Ononis fruticosa*, *O. Natrix*, *O. viscosa*, *Tradescantia virginiana*, *Arenaria*, *Sagina glabra*, *Phygelius capensis*, *Spiræas* (herbaceous), *Erigerons* (in variety), *Romneya Coulteri*, *Indigofera pendula*, hardy *Fuchsias* (in variety), *Hypericums* (in variety), *Spiræas* (shrubby), *Nandina domestica*, *Hedysarum multijugum*, *Menziesias*, *Ericas*, *Rhus*, *Ceano- thus* (in variety), bush and climbing *Honey- suckles*, *Calycanthus floridus*, *C. occidentalis*, *Carpenteria californica*, *Styrax japonica*, *Tricuspidaria dependens*, *Abutilon vitifolium*, *Andromedas*, *Vaccinium pensylvanicum*, *Stranvæsia undulata*, *Philadelphus*, *Viburnum Henryi*, *Metrosideros floribunda* (this has stood the winter and is now flowering freely), *Genista tinctoria*, Spanish Broom, *Robinias*, *Ozothamnus rosmarinifolius*, *Grevillea sulphurea*, *G. rosmarinifolia*, *Solanum crispum*, *Hydrangea hortensis*, *Clematis* (many species and hybrids), *Roses* (many species and varie- ties), *Eryngiums* (in variety), *Acanthus*, *Eupa- toriums*, *Verbascums*, *Delphiniums* (in variety), *Phloxes* (herbaceous), *Chrysanthemum maxi- mum*, *Galegas*, *Enotheras*, *Scabious*, *Berga- mot*, *Lavender* (in variety), *Tritomas*, *Alstræ- merias*, *Gazania splendens*, *Pentstemons* (in variety), *Calceolaria amplexicaulis*, *C. mexi- cana*, *C. plantaginea*, *Salvia patens*, *Stocks* (in variety), *Antirrhinums*, *Canterbury Bells*, *Anchusas*, *Forgeloves* (in variety), *Achilleas*, *Leptosiphons*, *Sweet Williams*, *Phacelia cam- panularia*, *Godetias*, *Clarkias*, *Carnations*, *Tufted Pansies* (in variety), *Liliums* (in variety), *Lupinus arboreus*, annual *Lupins*, *Sweet Sultan*, *Candytuft*, *Nepeta Mussini*, *Sweet Peas*, *Heimercollis* (in variety), *Butomus umbellatus*, *Polygonum polystachum*, *Cyperus longus*, *Rodgersia podophylla*, *Rheum acu- minatum*, *Nymphæas* (in variety), *Iris*es (in variety).

WORK OF THE WEEK has been largely of a routine nature. The Rose garden is now at its best, and the plants require frequent atten- tion in removing the old flowers, cutting back to a strong bud, thus inducing the plants to make fresh growth that will flower in the autumn. Many varieties of Hybrid Teas are excellent for autumn flowering, and these are encouraged to grow as much as possible by keeping the beds well supplied with water in dry weather and occasionally spraying with *Quassia* extract to keep aphid in check. Early-flowering *Chrysanthemums* have been looked over and all weak shoots removed, so as to allow sufficient room for the stronger ones to develop. Neat stakes have been placed in position, and the plants secured to them. Further looping in of the shoots will be neces- sary as the plants grow. Neglect of this often means ruin to the plants when sudden winds spring up. The herbaceous borders have been looked over, staking where necessary and securing shoots that need tying. All old flower-stems and any unsightly shoots were re- moved. The Dutch hoe is used freely to keep down weeds and promote a fine tilth. The old blossoms and seed pods are removed from *Tufted Pansies* in order to prolong their flowering. Neglect of this soon causes a total cessation of blooming, and the plants look starved and untidy. During drought it is necessary to afford copious waterings. Beds of herbaceous *Phloxes* have been given a good mulching of leaf-soil, and the growths of the plants supported where necessary. In the

rock garden the groups of each plant are regulated as soon as the flowering season is past. Seeds of all the choicer subjects are gathered and sown as soon as ripe. The watering of small alpine plants in the crevices of the rock garden is practised regularly, for into many of these positions rain seldom penetrates. The mowing of lawns occupies considerable time, while the cutting of Grass verges also requires frequent attention.

Lilford Hall, Oundle. F. W. G.

SOUTHERN COUNTIES.

Late Muscats.—As these are now stoning, close stopping of sublateral growths will, until the ordeal has been safely passed through, be suspended. By then the bark on the laterals will have assumed a nut-brown hue, thus affording outward indication that the perfecting of the seeds is complete. All berries which contain their full complement or nearly so of seeds will then commence visibly to swell again, but those which are seedless or contain but one seed either lag behind or fail to swell. This furnishes a safe guide when the usual scrutiny of the bunches takes place after the stoning is past as to which of the berries should through this defect be removed. Surplus but sound berries should also at the same time be nipped out wherever there is a likelihood of their being too close together as they approach maturity. This is the stage, too, at which the final dressing of artificial manure should be applied and washed in with a good soaking of tepid water.

Other late Grapes.—These, too, have begun stoning, and for some little time care is necessary to avoid scalding taking place. The principal cause of this malady, if such it can be termed, is a low night temperature, which causes the berries to turn cold and become covered with condensed moisture. Then when the sun strikes them in the early morning each globule of moisture acts as a lens, and scalding of the skins follows. The remedy is simple, and consists, firstly, in keeping the hot-water pipes warm throughout the night, which prevents moisture condensing and keeps the skins warm and dry. A chink of air at the apex allows moisture to escape, and at the same time tends to keep the internal atmosphere in circulation. Another thing is to avoid damping too heavily, and in extreme cases to omit doing so both at closing-time and first thing in the morning. Extra attention can then be paid to these matters during the day for the time being. The roots must not be allowed to feel the want of water, and when necessary to apply it choose a time for doing so when the ventilators are fully open. When the stoning is complete the bunches of varieties whose berries attain a large size should be looked over and a further thinning given where necessary. If very much growth has been made while stoning was in progress, stopping must be cautiously done, as the removal of a great quantity of growths at one time tends to paralyse the root-system and oftentimes leads to shanking. Where there is room for doing so, some of these shoots may with advantage be tied down to the trellis, as these tend to encourage further activity, and the greater the number of feeding roots the finer the berries and more perfect the finish.

Other vineries.—Houses in which the Grapes have just started colouring may be freely ventilated both at the top and front in warm weather. When very hot, the door or doors of the house may, in addition, be stood open also. Until the colouring becomes more advanced the house may be closed for an hour or two in the afternoon, but a little air must be admitted again at seven o'clock, both at front and top, and left on throughout the night. The object in closing is to facilitate the swelling of the berries, which, if all conditions are right, proceeds at a rapid pace when this stage is reached. Whatever is necessary in the shape of damping must in this case be done during the forenoon now. Vines in a less advanced stage must still be treated as mentioned in former notes.

Late Melons.—A house should shortly be cleaned and got ready for a late crop of Melons. In the meantime the plants to rather more than the required number should be raised by sowing seeds singly in small 60 pots,

Wall trees.—Young growths on Peach and Nectarine trees must be kept tied in or otherwise fastened back to the wall, as described in a former note. Extension growths on other trees should also have the same attention as they are difficult to deal with if once the wood is allowed to become crooked and deformed. This matter, important as it is in regard to trees which are fast becoming established, is still more so where young trees are concerned, as no after attention will remedy neglect in this direction.

Rose garden.—For the next few weeks this will be looking its best, and, as far as existing conditions will allow, such matters as the removal of spent blooms, stirring the soil to preserve a neat appearance and to a certain extent preventing mildew attacks, should have attention. A. W.

MIDLAND COUNTIES.

Vines.—As soon as the Grapes in early houses are cut the Vines are syringed copiously to cleanse the foliage. Later houses where the Grapes are swelling need looking after very closely during hot weather. Maintain a humid atmosphere by damping all places thoroughly several times a day. Air should be admitted freely when the weather is favourable, and as soon as the fruit commences to colour a little should be left on all night, as this tends to a more perfect finish. Keep the roots well supplied with moisture, and feed with an approved Vine manure or farmyard liquid at a reasonable strength to assist the Vines to perfect the crop.

Peaches and Nectarines.—Established trees bearing full crops of fruit are given occasional applications of liquid manure and Le Fruitier. Healthy trees in full bearing with their roots in a properly drained border require large quantities of water, particularly during the time the fruits are swelling. Continue to train the shoots and pinch the lateral growths so that the fruits will be the better exposed to sunshine. If any shoots are noticed to be extra strong it will be better to cut these out, as their presence is apt to rob the weaker growths.

Schizanthus.—A sowing of this will be made during this month in order to raise plants for spring flowering. Care must be taken to sow the seeds thinly, as overcrowding at the start is detrimental and may result in failure. When the seedlings are large enough to handle they are transferred to pots or shallow pans, placing them in a cool frame as near to the glass as convenient.

Cyclamen seed will be sown within the next few days. I prefer to sow the seeds in 6-inch pots, half filling these with crocks, placing over these a layer of Moss and then some of the rougher portions of the compost, finally filling to within 1 inch of the top with that portion of the compost that has been passed through a 3-inch sieve. Equal parts of loam, leaf-soil, and a little coarse sand form a suitable compost. Before sowing the seeds soak the soil with water applied through a fine rose. Sow the seeds thinly and press them well into the soil, being careful afterwards not to cover them too deeply. Give a final watering through a fine rose, and place the pots in a close, moist position in a temperature of 65 degs. to 70 degs.

French Beans.—The latest sowing of these has been made on a warm border and where it will be possible to afford protection at night in the autumn. Plants from this sowing will yield supplies late in the season, when those in exposed situations have been cut off by early frosts.

Winter Spinach.—A good sowing of Prickly Spinach will be made about the 20th of this month for use in late autumn, and another sowing about ten days later for winter and early spring supply. It is better to make two or three sowings during the month than to sow a large quantity at one time. The ground for this crop should be in good condition to ensure a free growth. If it has been manured for the previous crop it will require to be deeply dug and allowed to remain untouched for a few days until the surface is dry enough for treading, previous to which a good dressing of soot should be given, so that by treading and

raking the bed it may become thoroughly mixed with the surface-soil. When the bed has been made level draw drills at 18 inches apart and 2 inches deep. A careful watch for slugs must be kept over the plants raised this month, for if this crop is destroyed the season may be too far advanced to replace it.

Tomatoes in the open air.—The unsettled weather has been much against Tomato cultivation out-of-doors. The plants must be kept free from side-shoots to enable the light and air to pass freely among the blooms. When a few trusses of fruit have set on each plant the tops should be taken out. At this stage a top-dressing of artificial manure pricked into the soil with the point of a digging fork will encourage the development of the fruit.

F. W. GALLOP.

SCOTLAND.

Cœlogyne cristata.—Among the more accommodating Orchids, where there is not a special house for them, *C. cristata* is very useful, rivaling in that respect the *Cyripediums*. Just at the present time the young growths are coming away very strongly, and care ought to be taken that these are encouraged in every way. No hard-and-fast rules can be safely laid down with regard to the requirements of these plants much depending on the temperature of the house in which they are grown, the period during which the plants are exposed to sunshine, and the suitability of the compost in which they are grown. Every endeavour by means of regular attention in respect of moisture, light, and correct ventilation should be provided, and if the plants are kept clean and in good health excellent growth will be followed by plenty of bloom, the latter coming in very useful during winter or early spring, according to the temperature to which the plants are subjected as the time of blooming approaches.

Cytisus racemosus.—No one, I think, can have too many plants of this. Good specimens are useful for furnishing large houses, but equally valuable in early spring are small bushy pieces in 5-inch pots. During the week a quantity of strong cuttings was secured from old cut-back plants and inserted in Cocoa-fibre in the propagating-pit. Kept close, these, when well rooted, are put straight into their flowering pots. They are then gradually inured to a lower temperature, until, in September, they are put into a cool pit, in which they remain until removed to the greenhouse where they are to bloom. Naturally, being of vigorous growth and restricted to 5-inch pots, these plants appreciate plenty of liquid-manure given at close intervals, but in a weak state. Other plants which were potted off or repotted during the week included *Libonia floribunda*, Balsams for late autumn work, a good number of brightly-coloured *Coleuses*, *Lorraine* and other *Begonias*, *Tradescantias*, and some young pieces of stove and greenhouse *Thunbergias*.

Chrysanthemums.—Excellent growth is maintained in the case of winter-flowering *Chrysanthemums*. These are fewer in number than has hitherto been the case, and, with but few exceptions, they will all be grown in bush form, which, after all, is the most satisfactory way, except, of course, where exhibition is being contemplated. In the course of the week a beginning was made with the staking of the plants. At their present stage of growth the succulent young growths are very brittle and apt to be snapped by heavy rain. The final pinching has been given to such plants as required attention in that respect. Earwigs are at times apt to be troublesome, more so in some seasons than others, and a sharp look out must be kept in order that damage may be avoided.

Hardy fruit.—In many gardens the crop of fruit will be thin, always excepting Gooseberries, Currants, and Raspberries, which are fairly plentiful. Strawberries are in this district much later than usual, owing chiefly to the inclement spring and the continuance of unseasonable weather. In the case of wall-trees and fruit-trees in the open in general, the question of feeding will now be considered. A tree which is making luxuriant growth needs no assistance, but when the right season comes the roots may with advantage be

checked. It is the free-bearing tree which ought to be encouraged, and whatever manure is given, let it be given from the surface, either as a mulch or in liquid form. So far as the removal of useless wood is concerned, Peaches may be pruned at any time, and any naked branches dispensed with without delay. This is especially true of trees in pots. Stone fruits generally ought to have a firm root-run, but their roots must be well nourished. When fruit-trees are grown in the garden round the edges of vegetable quarters nothing should be planted within 4 feet of the trees, and the spade should not under any circumstances be permitted to encroach within the same distance.

Ferns under glass.—At no season of the year are Ferns under glass more attractive than now. The fronds of all the species have now reached their fullest development. Shade is necessary. In a general way it is not recommended that a lavish supply of chemical manure in solution be given to Ferns. The indiscriminate or careless use of concentrated stimulants is apt after a time to react upon the plants; and so, preferably, weak soot-water at fairly close intervals is, I consider, of more and lasting service. Highly fed plants never last long, and where good, sound loam forms the staple of the potting compost, but little artificial manure is necessary for everyday specimens. W. McGuffog.

Balmæ Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Calceolarias failing (Ayton).—The disease that has killed your Calceolarias is of a fungoid nature, the seat of this being in the bark at or about the collar of the plant. The only remedy is change of soil, with cool treatment at all stages, to secure strong, healthy plants to turn out early in the spring. In a few words, grow the plants hardily, lift with good balls, plant carefully, water well during dry weather, and mulch freely.

Thrips on Rose (F. Marshall).—Your Rose has been attacked by thrips and red-spider, the cause of which is dryness at the roots. You ought to give it two or three soakings of water, and at the same time a heavy mulch of good, rotten manure. Syringe it freely every day for a time, and if the weather is dry water freely. This will get rid of the pest, and with due attention the plant will in time recover.

Ivy-leaved Pelargonium sporting (Mother of Thousands).—The white flowers that have appeared on the pink-flowered Ivy-leaved Pelargonium are known as a sport. If you put in cuttings of the shoot on which the white flowers are borne the young plants will in all probability bear white flowers. The Wistaria will, no doubt, flower in time, but it would be far better to plant it out against a wall in the open air, so as to allow it more freedom of growth.

Seedling Zonal Pelargoniums (D.).—Seedlings of these plants are almost always gross growers. The best way to get them into flower fairly early is to shift them into 5-inch pots, and let them remain in these and grow as tall as they like, not pinching them at all. The first object is to see colour and quality of flowers, and plants so grown usually give these at the first in good form. If not liked, the plants may be thrown away. If they are pretty good, then tops should be taken off and rooted as cuttings in small pots, and these will later show the exact character of the variety.

Fuchsia buds failing to develop (W. J. S.).—You give us no clue whatever as to your treatment of the plant. An excess of stimulants, with too much water at the roots and a close, stuffy atmosphere, will often cause Fuchsias to behave as yours are doing. Discontinue manure-water, if you have been giving the plant any, give plenty of fresh air, and your Fuchsia will soon recover. You are keeping the Ivy-leaved Zonal Pelargoniums too close; what they want is more air. We found traces of green-fly on the leaves of the Ivy-leaved plant, and this pest, if allowed to gain the upper hand, would very soon ruin the plant.

FRUIT.

Peach-trees unsatisfactory (J. Ross).—Your Peach-tree leaves are what is known as blistered, the result of either frost or cold winds on the tender foliage. There is also green-fly on the leaves. First go over the trees, remove all the worst leaves and burn them, then syringe in the evening with Tobacco-water or Quassia extract. Repeat the syringing in a few days in case any insects escape.

SHORT REPLIES.

Tipperary.—1, Your Potatoes have been attacked by the Potato disease (Phytophthora infestans). The variety is evidently one very liable to disease. Had you sprayed the haulm when first noticed, it is just possible that you might have checked it. 2, Your best plan would be to get the list of some maker, and make a selection for yourself. The prices vary. You can get a very good one suitable for your purpose for about 21s. 3, Of very little value to a practical gardener.—**F. E. A. V. B.**—The best way is to pound the egg-shells up and feed them to the fowls.—**J. B.**—Do you mean summer pruning? If so, this should be attended to at once.—**Margaret Hills.**—The Rose you send is one of those that refuse to open well, and we should advise you to destroy it and replace it with one of the many fine Hybrid Teas now to be had.

NAMES OF PLANTS AND FRUITS.

Names of plants.—**Thos. M. Skinner.**—Hydrangea petiolaris.—**J. F. G.**—1, Inula glandulosa; 2, Helixine Solieroli.—**Mrs. Oliver.**—Arum Dracuncul.—**T. Butler Cole.**—Platyedon grandiflorum.—**W. Grant.**—1, Polystichum angulare; 2, Lithospermum purpureo-crenulatum; 3 and 4, Specimens insufficient.

Name of fruit.—**Gilbert.**—Apple: Reinette de Canada.

Roses.—What is the name of the carmine sport of Mrs. Laing (H.P.)? What are the two best strong-growing H.T.s? Coppery colour, free-flowering, and fairly full flowers wanted.—**G. H. R.**

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

It having been found inadvisable to hold the usual festival dinner this year in aid of the funds, the Committee of the Gardeners' Royal Benevolent Institution have issued the following appeal:—

May we plead for your practical sympathy on behalf of the Gardeners' Royal Benevolent Institution, a most deserving national horticultural charity, the immense benefits of which we can vouch for to many most worthy and necessitous men and widows. We hope you will kindly cheer the Committee by sending a subscription or donation to help them to maintain the good work which has been of such great value during the last seventy-eight years. The demands on our resources are ever on the increase, but never more so than at this present crisis in our nation's history. We urgently need funds to support the 265 annuitants, and there are no less than forty-two applicants anxiously awaiting aid, of whom sixteen are widows, who cannot be assisted from lack of means, and which number is constantly being added to. We therefore earnestly appeal for your generous financial assistance.—We are, yours very faithfully,

GRENFELL, F.M., President of the Royal Horticultural Society.
HARRY J. VEITCH, Treasurer and Chairman of Committee, G.R.B. Instn.
GEORGE J. INGRAM, Secretary.

A GLOW OF GLORIOUS COLOURS

200 BEDDING PLANTS, 2-

10 Pink Beauty, Sweet Williams, Begonias, Fuchsias, Lobelia Asters, Coreopsis, Phlox, Mignonette, Indian Pinks, Gyp., Alyssum, Sultans, etc., etc., packed separate and free on rail, 2s.

12 HARDY CHRYSANTHEMUMS, 1- Crimson, white, pink, orange. Strong plants, 12, 1s.

6 GIANT BEGONIA TUBERS, 9d. Enormous size bulbs, showing flower, doubles and singles; will make a beautiful autumn display.

40 STOCKS, 40 ASTERS, 20 ANTIRRHINUMS, 1/- Each packed separate, post free 3d. extra.

PREPARE YOUR WINTER'S FOOD. 300 VEGETABLE PLANTS, 1-

50 Savoy, 50 Xmas Cabbage, 50 Cauliflowers, 50 Kale, 100 Onions; or with 25 Lettuce, 25 Beet, 25 Beans, 6 Cucumbers, 6 Marrows, 1s. 6d.

AWARDED DIPLOMA AND MEDAL AT THE ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION-1912-
 THE MOST PERFECT FERTILIZER FOR
WAKELEY'S Celebrated HOP MANURE
 (PATENTED)
 THE ONLY RELIABLE AND COMPLETE SUBSTITUTE FOR STABLE MANURE
 GREENHOUSES, GARDENS, LAWNS, &c.

SCIENTIFICALLY AND CHEMICALLY PREPARED.
 In the form of a leaf-mould, ready for use at any time, in the same way, and for all purposes that stable manure is put. Goes further (1 cwt. equalling 15 cwts.) gives better results, is clean to handle, sweet smelling, and free from weeds, worms, etc.
 Report of Royal Horticultural Society. "Your Patented Hop Manure has been used in the Society's Gardens at Wisley, and I am pleased to report that it has proved excellent for the flower borders, fruit and vegetables grown both under glass and out in the open air."
 A beautiful Free Booklet giving full particulars and testimonials sent on receipt of postcard.
Beware of Imitations; Genuine only in our marked bags, containing guaranteed analysis.
 Sold in Bags, 28 lbs., 2/3; 56 lbs., 3/6; 1 cwt., 6/-; 5 cwts., 28/9; 10 cwts., 55/-; for cash with order, we paying carriage by Pickford, London district, or to any station within 25 miles of London; 3d. per bag charged extra for every 50 miles or part beyond this distance.
WAKELEY BROS. & CO. LTD., 71, BANKSIDE, LONDON.
 Also **WAKELEY'S GROUND GARDEN LIME, 2/-** bushel bag, carriage paid 25 miles, extra as above.

FALSE GARDEN DESIGN.

THERE is so much stupid and thoughtless work done in the name of garden design that part of the following protest made by Mr. E. Swale in the *Gardeners' Chronicle* deserves a thought. Such absurd work as carried out by people of the building order, who think that a garden should be adorned on the same principle as the decorations of a house, has given us the sham Italian garden. It is a survival of the old idea of the Dutch and Germans, who cut trees into the shapes of walls, and is as dead as a door-nail. The expense of it was a very great evil, apart from its ugliness, because so much money was spent on it that there was not much left for the true object of a garden, which is to grow beautiful living things. Among the unwise things done was cutting little canals quite near the house and tub-holes on the face of the garden, or even right against the house. These absurdities were ugly and dangerous, and served to increase the number of insect pests.

How often we find in the best regulated gardens of the present-day type some things as incongruous as those of "Cremorne" or "Rosherville" of long ago! It is surprising that in some gardens, otherwise beautiful, there still lingers a strong suspicion of those false Italian styles. We are rapidly losing touch with the garden, as a garden, and it is becoming a mere crowded place of artistically-placed vases, walls, pergolas, and Lily ponds, without meaning or reason, with only a secondary thought, if they are considered at all, to the flowers and shrubs to be grown there. The first consideration on laying out a site is where to place the imitation stone sundial, which is generally in a prominent place where the sun does not touch it. That is of no consequence if placed at the end of a long stone-flagged path, most artistically paved with broken slabs, so that small, creeping plants can be placed between the joints for the special purpose of being trodden on. No self-respecting modern garden would be without this absurdity. In looking over the pages of your contemporaries it has struck me that Lily ponds and troughs for water-plants are invariably death-traps to children and old people. There are two forms I take exception to. The one that is placed across a well-defined walk or

avenue, where the eye carries one beyond, and gives the assumption of a continuous safe path. The other where steps lead down from a summer-house or terrace and plunge you up to the neck among the frogs.

Everyone must have a rock garden nowadays, and one sees banks strewn with unsightly boulders, of all shapes and material, that would give any geologist fits, and of the most unlikely strata—often, of course, in the wrong position, and suggesting fearful earthquakes at a very recent period. A rock garden we will have at all costs, and yet we despise the old lady who saved up all the best bits of coloured china and glass to place on her rockery, because she said "it made it look so bright and cheerful." You have noticed, also, what a tendency there is at the present time to plant the garden with old oil jars and heavy terracotta vases, that look like the remnants of Belshazzar's Feast, or the overflow from the "Forty Thieves." I always have a great longing to play skittles when I see them. Near me there is a shed with a corrugated iron roof, on which is planted the blue Iris, the idea being to cover up the unsightliness—but can anyone, especially a lover of his flowers, conceive a more unsuitable place than this for an old favourite. The "vogue" for strong contrasts is responsible for the white garden furniture dotted about our lawns and now so fashionable, but to anyone with a sensitive eye this is as bad as newspapers scattered about. All objects that glare, or attract attention, other than flowers, should be avoided.

NOTES OF THE WEEK.

The Maiden Pink (*Dianthus deltoides*).—There are some bright forms of this native Pink as well worth a place on the rock garden as any of the race. I use it freely as an edging plant and also for low retaining walls.—W.

The Azores Forget-me-not (*M. azorica*).—Rich as we are now in the blue Forget-me-nots, it is a pleasure to see this fine dark purple *Myosotis*. It is easily raised, but, being a little tender, is often lost or forgotten. It should be raised from seed now and then to keep up a stock of one of the most interesting plants for the rock garden. From Sir Frank Crisp.

The Golden Flag (*Iris aurea*).—This fine Iris is happy in any moist border or among shrubs, but the best effects from it are among reeds and waterside plants. It is not there so strong as when grown in rich soil, but the effect is better, even though the flowers be fewer.—W.

Lonicera tragophylla in Scotland.—This Honeysuckle, first shown at the International Exhibition in 1912, is doing well against a wall at Monreith, Wigtownshire, Sir Herbert Maxwell considering it one of the best of the race. The flowers are large and yellow, but they have not the fragrance which we associate with most of the *Loniceras*. It is a rare plant in gardens and has as yet found its way into few books of reference.—S. A.

A fasciated Foxglove (*A. E. Tomlinson*).—The cup-shaped bloom you have on the point of the spike of the Foxglove is by no means uncommon. We have seen them frequently on plants of the garden strains of *Digitalis*. It is the product of two or three blooms fasciated or run into one, and has nothing to do with the Canterbury Bell. Seeds saved from the resulting pods have been frequently sown in the expectation that similar flowers would be produced, but no such thing has invariably happened.

Habranthus pratensis.—Sir Herbert Maxwell, Monreith (page 229), states that this fine *Amaryllid* is not admitted to the "Kew Hand List" of 1902. It is, however, to be found in both the "Hand Lists of Tender Monocotyledons," namely, in that published in 1897 and that of 1915. In both instances the genus *Habranthus* is referred to *Hippeastrum*, the species under notice being given as *Hippeastrum pratense*, Baker, Chili. In the 1915 edition the recently-adopted spelling of Chile is followed.

Pink Progress.—"E. B. S." had some interesting notes on Pinks in the issue of June 17th (p. 296), but he made no reference to the above, of which I have a nice display from a group of eighteen plants on a west border. Its peculiar colour, a magenta shade, makes it unsuited to be placed indiscriminately, but the large flowers look handsome near clumps of the old dark blue Spiderwort (*Tradescantia virginiana*). Some people, seeing it for the first time, think it a variety of border Carnation, but it has the true Pink scent, and flowers at the same time as other Pinks. Unfortunately, it has the drawback of Mrs. Sinkins and Her Majesty, a split calyx, though its tall habit—18 inches

—big flowers, and uncommon appearance make one almost willing to overlook this fault.—C. T.

Deutzia gracilis carminea.—We owe much to Messrs. Lemoine, of Nancy, for the beautiful shrubs they have raised and introduced to gardens. The Deutzias they have raised are numerous, but among the prettiest is *D. gracilis carminea*, which has all the grace of *D. gracilis*, with its elegant arching, slender branches. To this has been added the distinct colouring of the flowers, which are carmine-pink in the bud and clear rose when open. In one of the borders at Monreith I saw it lately in fine flower.—S. ARNOTT.

The Gentianette in 1916.—This (*Phacelia campanularia*), one of the most beautiful plants of the Californian flora, may often be sown in the open ground with success, but this year the seeds have not come up. It may have been due to bad seed, as last summer was not a good one for seed-sowing. Happily, some plants of last year seeded in a rose bed, and the result is now (in mid-July) a fine bloom on strong, sturdy plants. The spring-sown in normal years usually grows thickly together and the bloom is often short-lived. The best way I see now is to sow in autumn thinly in some bed or border not to be dug over. This plan need not prevent sowing in spring (April), and both may be carried out over a large part of the southern country.—W.

The Letton House Briar.—I think Mr. Arnott has confused this variety with some other. I received it several years ago from Miss Anderson, Barskimming, Ayrshire. Mr. Arnott describes it as an early bloomer, and that "Pink Arches" is a later variety. Now the variety we have as Pink Arches is passing away before the first flower opens on the Letton House Briar, which is now (July 12th) at its best. The latter is certainly not a variety of *R. alpina*, but it is a very choice subject to form an isolated bush on a lawn, requiring no pruning beyond occasional removal of old wood, growing about 8 feet high and about the same in diameter, well furnished all round, and producing a fine mass of single, deep pink blooms.—HERBERT MAXWELL, *Monreith*.

Repotting Ferns.—I quite agree with the reply at the end of Chas. T. Drury's criticism of the notes upon Ferns (p. 234). Mr. Drury is altogether wrong if he pots his Ferns while they are in a dormant state, and any success which he may have attained by following that method is more a matter of good luck than of good guidance. The correct time, of course, as the note indicates, is when the plants are well on the move, the reason being rightly given. No practical Fern grower would repot or divide his plants when dormant. Mr. Drury's petulant objection to the advice given in connection with turning the plants in order to induce symmetry is neither here nor there; the matter is entirely one of personal opinion, and one opinion is as good as another in such a trifling affair.—W. McG.

Saxifraga Dr. Ramsey.—This, one of the best of the silvery summer-flowering hybrid Saxifrages, is said to have resulted from crossing *S. longifolia* and *S. cochlearis*. There is practically no evidence of the *longifolia* influence, and one would rather have suspected, both from the leaf growth, the size of flowers, and their copious spotting of reddish-crimson, that *S. Macnabiana* had in this instance been wedded to *S. cochlearis*. The stature of the hybrid also agrees with these, as does the time of flowering. In any case Dr. Ramsey is too good to be absent from any collection of June-flowering varieties.

Besides being of a genial nature and easy to grow, it also seeds freely, the seedlings showing considerable variety of leaf-growth. The plant itself is not, however, slow of increase, and the offsets, pricked off in an inch-deep bed of pure sand, soon make roots, the single rosettes attaining 2 inches to 3 inches across. At flowering time the hybrid reaches 8 inches or more high, the graceful arch of the flower-sprays but adding beauty to a plant of distinction and merit.—E. H. JENKINS.

Gentians in Grass.—It is, as "W." justly remarks, hopeless to attempt to grow *Gentiana verna* in lowland Grass. We find no difficulty in growing it at the foot of a rock wall in gravelly loam with lime, provided that when the plants begin to thrust themselves out of the soil, and before they get leggy, fine gravel and loam are spread thickly round them and worked into the tufts. The common Stonecrop (*Sedum anglicum*) forms a pretty and helpful carpet for this Gentian. The Willow Gentian (*G. asclepiadea*) is easily naturalised in woods and meadows, where it seeds itself abundantly. I do not know whether it dislikes lime, but it certainly does not need it.—HERBERT MAXWELL, *Monreith*.

A Valerian-covered quarry.—Passing through Gravesend in early June I was struck with the beauty of an old disused quarry of considerable extent. The perpendicular walls, over 30 feet in height, were ablaze with both red and white Valerian, the soft grey of the walls peeping through at intervals giving additional effect and relief to this beautiful picture. The Valerian—evidently assisted by the air in the district—had found a foothold, and revelled under the conditions. The beauty of the Valerian in such a position is a striking lesson to those who possess one of these old quarries, and clearly demonstrates how, with a few plants put in along the higher ledges, time and Nature will do the rest. I noticed, too, that a railway ran past one end of this quarry, and in gorgeous masses on both banks, growing freely among the long Grass, was this plant. I have often seen the Valerian on low walls in Devonshire forming long, broad masses, but the magnificent display produced in this quarry and on the railway banks at Gravesend surpassed in effectiveness anything previously seen.—PRE. E. M., *64th Prov. Batt., Suffolk Regt.*

Alstroemeria aurantiaca.—I have been struck with the rapid growth which this makes from seed when in congenial surroundings. The seed takes a long time to germinate, but if sown in the autumn as soon as ripe it will germinate freely the following spring. The young plants then make rapid progress—more below than above ground, I think, for there does not seem much in the way of stem or leafage to show by the end of the growing season, but the following spring up come great strong-flowering stems, which grow several feet high and flower as freely as if the plants had been long established. I think the reputed capriciousness of this species arises from its intense dislike to being moved more than from any other cause, as it does not seem at all particular as to soil provided this be light and well drained and the position sunny. After being moved it seems to sulk for two or three years, as Mr. Cornhill describes (page 336), and it is therefore best, and saves time, to grow it from seed, which should be sown where it is to bloom if possible, or else one or two seeds in a pot, to be planted straight out subsequently without disturbing the roots in any way. It is worth taking some trouble over, for it is

a gorgeous subject either for the border or for cutting, and a large group in full blossom is a sight to be remembered.—N. L.

Mutisia decurrens in Scotland.—The handsome *Mutisia decurrens*, from the Andes of Chili, is rare in gardens. It has a habit of dying off and only a few appear to succeed in establishing it permanently. It has, however, been successfully grown even in Scotland, and I understand there is in an Edinburgh nursery a plant which has occupied its present position for quite a number of years. When Mr. T. Hay, of Greenwich Park, was at Hopetoun, it was cultivated there with success against a wall. At Monreith, Sir Herbert Maxwell has two good plants, one in a warm position against a wall, and the other in the partial shade recommended for it in gardening books. The former is the better of the two and looks as if it had become established, as it is sending up suckers round the original stems. From what I have seen of this *Mutisia* I consider its loss is often due to cultivators being too anxious to propagate it by removing the suckers instead of allowing most of them to remain.—S. ARNOTT.

Ozothamnus rosmarinifolius.—This pretty composite has been flowering uncommonly well this year, and large bushes white with the miniature clusters of starry flowers in May and June make quite an effective picture in the landscape. It is distinct, too, a fact which counts for much. The species seems far more hardy than is usually supposed, and while in the Isle of Wight I have seen it trained to a wall with very indifferent results, I recently saw a nearly 8 feet high bush of it in Lady Arthur Paget's garden on Kingston Hill sharing with Hollies and the hardiest of things the fullest exposure. The natural soil is light and warm, a fact which may, to some extent, account for the excellent health of so fine a plant. The "Dictionary of Gardening" gives its height (in Australia) as "8 feet to 9 feet," hence the plant referred to is of quite mature size, while such success so near London should tempt others to try it. The flowers possess a peculiar and distinct odour, and whiten appreciably after removal from the plant. A spray of it in a room and not in water for the past three weeks unmistakably proves this.—E. H. J.

The Silk Vine (*Periploca græca*).—This is well worth attention by reason of its luxuriant growth, purplish blossoms, and curious fruits. It is easily distinguished by its milky juice, for if a twig is broken or a leaf removed the milk-like sap exudes at once. The branches attain a height of more than 20 feet when growing near a suitable support. The flowers appear in June and July, each one being about an inch across, dull purple in colour, several being borne together in clusters 3 inches across. The cylindrical fruits, each about 5 inches long, are borne in pairs, the seeds, as is common in the Asclepiad family, being surrounded by silky hairs. The home of this climber is South-Eastern Europe, and it is one of the plants that attracted the attention of our soldiers in Gallipoli last summer, for fruits have on several occasions been received from them for identification. Like other strong-growing climbers, it is seen to greatest advantage when planted at the base of a large bush or small tree, over which it may ramble at will.—D.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

PLANTS AND FLOWERS.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

NYMPHŒA COLOSSEA.

THIS is the noblest, so far, of the white Water Lilies raised by M. Latour-Marliac, and, if he had never given us anything else, it would have been of great service to our gardens. I have it in open water fearless and beautiful every year. The group shown is in a small pool where it does even better, the flowers being more protected by their surroundings. It is hardy under all conditions. W.

SAXIFRAGA CALABRICA.

I WOULD recommend every lover of choice Saxifrages who is not already possessed

flowers equal to those of the best *S. longifolia*; indeed, the flower effect is, that of the latter, the leaf growth that of an enlarged *S. lantescana*. Its chief garden value, however, lies in the fact that, given generous treatment, it is a perennial-flowering *S. longifolia*, hence good enough for all. In the open it flowers in June and into July. E. H. JENKINS.

NOTES AND REPLIES.

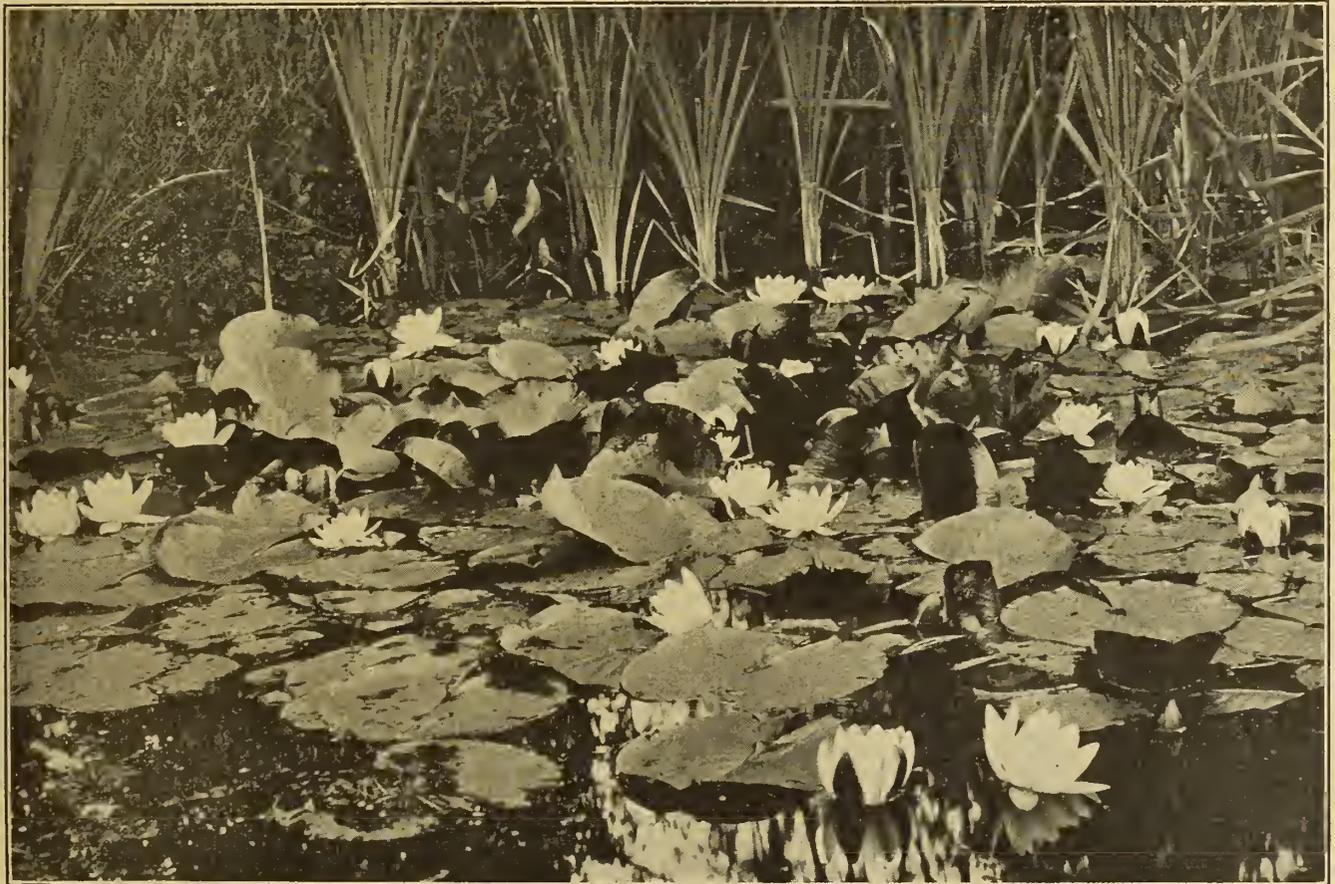

Wall plants.—I know the garden well from which "Kirk" writes, and can bear out what he says about *Erinus alpinus* on the walls thereof. *Centranthus ruber* I know well on many walls, while *Linaria Cymbalaria* is a nuisance in some places on walls, but gives a veil of beauty on others. I know some old gardens where *Campanula muralis* has become established on the walls, greatly to their adornment. A very uncommon wall plant, so

among the stones of a retaining wall in a hot, dry position in limy soil. I do not think it is particular about lime, as I have seen it growing like a weed in poor, sandy, peaty soil on the flat, under the shelter of a south wall. The flowers, which appear in August and September, are of a lovely shade of blue, and the foliage turns red in the late autumn, thus prolonging the charm of the plant. No rock garden should be without it.—W. O.

INDOOR PLANTS.

NOTES AND REPLIES.

Clerodendron fallax.—This is very useful for the greenhouse at this period of the year, for, though early in the season it requires a warmer structure, no fire-heat is needed during the summer. It may be readily increased from cuttings in early spring, and if the young plants are grown on freely, good flower-

Nymphaea colossea. Hillbrook Place, mid-July.

of this good kind to obtain plants of it without further delay. It came to me quite accidentally as *S. catalaunica* a few years ago when hunting for extra large plants of *S. Cotyledon pyramidalis* for an order. The firm had none of *S. Cotyledon pyramidalis*, but strongly recommended *S. catalaunica*, which they then grew in its place and found it better. Recognising there was something wrong, and knowing the firm would not be growing for market work anything of an inferior character, I ordered a few as a sample, and received what, in the solitary rosette, appeared to be a broad-leaved, vigorous-growing *S. longifolia*, and, for convenience and want of a better name for the moment, called it *S. longifolia latifolia*. Later I got its correct name, which is given above. It is supposed to be a hybrid between *S. longifolia* and *S. lantescana*, and there is much evidence of such a cross. From single rosettes (seedlings) I have had plumes of

far as my observation goes, is *Saxifraga Cymbalaria*, which I saw the other day in thousands on two walls at the old garden at Monreith. One of the walls was of the usual stone type on which fruit trees are trained, and in the crevices there was a host of plants of this little yellow Rockfoil. The other wall at Monreith is an old Moss-covered one, more likely, from an orthodox point of view to be covered with *S. Cymbalaria* than the other, and it, too, was the happy home of a wealth of flowers. The Saxifrage looked better against the Moss on the old wall, but it was very beautiful on both. In some places the Sedums are at home in these old walls.—S. ARNOTT.

Plumbago Larpentæ.—This can be propagated quite easily now by cuttings taken off close to the root and inserted in sandy soil in a cold frame and kept close for a week or two. It is said to be a wall plant, and it certainly is very happy with me planted

ing examples in 6-inch or 7-inch pots may be obtained. No stopping is needed, as the plant is most effective as a single stem terminated by a branching panicle of rich scarlet flowers. When growing, red-spider must be guarded against, and liquid-manure is very helpful when the pots are well filled with roots. Seeds of this *Clerodendron*, from which young plants can be raised, are often produced, but, as a rule, germination is very irregular.—W. T.

Hydrangeas.—Specimen plants having from five to seven shoots which are required for forcing gently into flower during May and June next season, having completed their growth, have been stood outdoors in full sun to get the wood well ripened. Until this is accomplished and the foliage ripens, watering must in no wise be neglected. For this reason, and they being such thirsty subjects, the pots should either be plunged to the rims in a bed of ashes or stood near to the water supply.

Statiche profusa.—This appears to be rather a difficult subject to propagate from cuttings, but for once in a way the percentage which has satisfactorily struck has been fairly high.

Although strictly speaking a greenhouse plant, this *Statice* appreciates the higher temperature and moister atmosphere of the stove in its early stages, and, accordingly, the young plants will be permitted to remain in that structure for some time. *S. profusa* is especially valuable for associating with Carnations under glass, a combination of this plant and such a variety as *Carola* being highly effective.—KIRK.

Zonal Pelargoniums.—These should now be fully exposed night and day and be fed with diluted liquid so soon as the pots become well filled with roots. Each plant must have ample space for development, on which account the whole of them should be stood widely apart. To ensure shapely and bushy plants pinching must, as required, be attended to.

GARDEN PESTS AND FRIENDS.

SUMMER SPRAYS AGAINST AMERICAN GOOSEBERRY-MILDEW.

(Continued from page 356.)

THE failure of soft soap used alone to give the spray fluids under trial the necessary degree of wetting power led eventually to the use of

SOFT-SOAP-AND-PARAFFIN EMULSION. From previous spraying trials against woolly aphis on Apple-trees it had been found that with the comparatively hard water at Long Ashton the most wetting combination was an emulsion of paraffin in soft-soap solution at the rate of 20 lbs. of soap and 2 gallons of paraffin to 100 gallons of water. With soft water not more than 15 lbs. of soft soap need be used. This emulsion, both when used alone and when various fungicidal substances were dissolved in it, proved capable of completely wetting the densest patches of mildew. Even when a fungicide was not added to it, it appeared to possess a marked toxic action on the mildew, the conidia, so far as could be judged in the original trials by a microscopical examination, being killed after contact with it. The results of subsequent experiments tended to show that the emulsion alone could not be relied on to kill the "summer stage" completely, and on that account it was eventually decided after trial to use it in conjunction with liver of sulphur for the main 1915 experiment. This experiment was an attempt to stamp out, if possible, the "summer stage" of the mildew from a fairly well isolated Gooseberry plantation in the neighbourhood of Weston-super-Mare, with the object of ascertaining if the disease would re-appear the following season after this treatment supplemented by winter tipping, and, if so, if the time of the outbreak was delayed sufficiently for the fruit to escape infection. The fungicide used was the soft-soap-and-paraffin emulsion referred to in a previous paragraph, with the addition of liver of sulphur at the rate of 3½ lbs. per 100 gallons of the fluid, *i.e.*, a 2 per cent. emulsion containing approximately 0.35 per cent. of liver of sulphur.* From the preliminary trials it appeared that, when applied with reasonable care, this fluid was capable of completely wetting and killing the mildew, and that at the same time it caused no scorching or defoliation and no disfigurement of the foliage or fruit. The

PLANTATION TREATED consisted of bushes of *Whinham's Industry* and *Keepsake*, and was situated 100 yards or more from the next plantation of Gooseberries, in which the disease also occurred. The outbreak appeared in May, and by the be-

ginning of June the berries and young shoots of the *Whinham* and the young shoots of the *Keepsake* were freely attacked. The fruit of the former variety was largely covered with the summer stage and remained ungathered on the bushes throughout the course of the experiment. When the disease appeared to be at its height about the middle of June the spray was applied, care being taken to wet the whole of the bushes thoroughly. An examination of the diseased shoots and berries a few days later showed that the production of new conidia had ceased, and that the fungus originally present had apparently been killed completely. It had originally been intended to spray the bushes again at intervals during the remainder of the summer, but, except for a very slight new outbreak on a few of the shoots of the outermost bushes of the *Whinham's* plot, no further growth of the mildew occurred. It was, therefore, considered unnecessary to give any further spraying. There was no damage done by the spray fluid to the bushes except in the case of a few *Keepsake* plants, which received the last portion of the fluid. In this instance some scorching appeared and was evidently caused by too great a concentration of emulsion, owing to lack of agitation in the knapsack machines used. On the few shoots which eventually showed the living "summer stage," the "winter stage" appeared also in due course. Very few perithecia were formed, and in none of those examined were ripe spores observed. The critical test of the experiment is, of course, the re-appearance of the disease and the time of the outbreak this summer. As to this, nothing can yet be said, but the experiment last year certainly serves to show that the liver-of-sulphur-soft-soap-paraffin emulsion is capable of drastically reducing the amount of the "summer stage" in an affected plantation and, provided that the spraying is administered as may be necessary, also of correspondingly curtailing the production of the "winter stage." Further than this conclusion it would be at present unwise to go. It is probable that the character of the weather last season and the heavy crop of berries carried by the bushes prevented the formation of the succulent young shoots on the bushes which are mainly the object of attack, and that the spread of the disease from the few shoots which bore living conidia after the spraying was accordingly hindered. On this account no satisfactory conclusion can yet be drawn as to the number of sprayings required to keep the "summer stage" under control. Trials in a plantation of young, vigorously-growing bushes are required for this purpose. The

COST OF THE MIXTURE at pre-war price per 100 gallons works out as follows:—

Soft soap, 20 lb. at 14s. per cwt.	2s. 6d.
Paraffin (Solar Distillate), 2 gals. at 7d.	1s. 2d.
Liver-of-sulphur, 3½ lb. at 8d.	2s. 4d.
Total	6s. 0d.

It should be remembered, however, that owing to its good wetting power less solution is used per bush than would otherwise be the case. With soft water 15 lbs. of soft soap per 100 gallons would be amply sufficient, thus reducing the price to 5s. 4d. per 100 gallons. As to the mixture itself, it is believed that, where the treatment of the "summer stage" of mildew by a "hitting" fluid is concerned, the employment of a wetting fluid of the paraffin emulsion type is essential, and, so far as trials to date go, none approaches the 2 per cent. soft-soap-paraffin emulsion for effectiveness and cheapness combined. The choice of an active fungicide to sup-

plement the toxic properties of this emulsion is still an open question, as indeed is the need for the inclusion of such a substance. Liver of sulphur was selected, to some degree arbitrarily, for the experiments which have been described, and appears to have acted very successfully, but further work may well show that there are better fungicides for the purpose. In this connection it will be interesting to test in its place ammonium sulphide, the substance which has proved so promising in the experiments of Messrs. Eyre and Salmon. It seems possible that the effective results with the latter fungicide may have been due not only to its action in the form of a "hitting" spray, but in part to its decomposition into volatile substances, which acted in a gaseous condition upon the fungus. Where "vapour" treatment is concerned the wetting properties of the fluid applied are not so vital, and 1 per cent. or less of soft soap in the mixture might then be adequate for effective distribution.

It remains to be added that the liver-of-sulphur-soft-soap-paraffin mixture probably possesses very limited protective properties against re-infection, and that renewed infection from outside sources can doubtless occur freely, even although the fluid may completely clear the plantation under treatment from the original "summer-stage" attack.—*Journal of the Board of Agriculture.*

—Experiments which have been conducted during the last three years at Wisley on the American Gooseberry-mildew have this year been productive of striking results. By the use of a modified form of Burgundy mixture an outbreak on the foliage and berries of over 100 bushes comprising several varieties of Gooseberry exposed to infection has been completely prevented.

The mixture was used according to the following formula:—Strength I.: Copper sulphate, 8½ ozs.; washing soda, 9½ ozs.; soap, 100 ozs.; water, 100 gallons. Strength II.: Copper sulphate, 40½ ozs.; washing soda, 45½ ozs.; soap, 100 ozs.; water, 100 gallons. The chemicals were dissolved separately, the solutions mixed when quite cold, and the soap added last. Both strengths proved effective. Spraying took place on May 20th at 6 p.m. (Willett's time), when the bushes were just dry after gentle rain in the afternoon. In the experiment the sprayed and unsprayed bushes were situated in a square of 100 square feet area, outlined at the angles by old bushes to provide sources of infection. There are within each square three unsprayed bushes and one sprayed bush of the same variety. Of the sixty squares over forty are now infested with mildew, some very heavily, the outbreak occurring chiefly in the berries. At the time of writing no mildew has been detected in any of the sprayed bushes, even when completely surrounded by infested ones. Whereas all the berries on the sprayed bushes are absolutely free from mildew, many on the unsprayed bushes are heavily infested with the early "white" stage of the disease. In a further experiment all the bushes in a small plot adjacent to the main experimental area were sprayed and are now also free from mildew.

Burgundy sprays leave a fine deposit on the berries, consisting of a mixture of the precipitates of copper carbonate and sodium sulphate. But since nearly the whole of this deposit can be removed by a sharp rinsing in tap water there should be no difficulty in devising a plan for thoroughly cleansing the berries.

DR. HORNE.

R.H.S. Gardens, Wisley.

* The mixture is made as follows:—In 5 gallons of boiling water 20 lb. of soft soap and 3½ lb. of liver-of-sulphur are dissolved by constant stirring. Two gallons of paraffin (preferably "Solar Distillate" brand) are forcibly sprayed into the hot solution, using a garden syringe with a rose attached for this purpose. For use add 19 gallons of water to every gallon of concentrated emulsion.

ORCHIDS.

THE MOCCASIN-FLOWER
(*CYPRIPEDIUM SPECTABILE*).

This, the finest of all the hardy *Cypripediums*, is one of the most amenable to cultivation in this country. The illustration depicts part of a group of this, planted in the autumn of 1914, thus showing how quickly it may be established, given suitable conditions. A somewhat shady and low-lying position in the rock garden was selected, the soil dug out to a depth of nearly 3 feet, a foot of broken bricks placed in the bottom for drainage, filling up with a mixture of rough peat, fibrous loam, well-decayed leaf-soil, a little sand and charcoal, and chopped *Sphagnum Moss*. In planting, wide holes were made and the roots spread out horizontally, with the crowns about 2 inches below the surface. The soil was well worked in between the roots, making the whole firm, taking care not to injure the crowns.

ture is a few degrees warmer, but such treatment is not really essential. If kept in the cool-house for the winter the atmosphere must be fairly dry or black-spot will attack the foliage. The most suitable time for

REPOTTING is a few weeks after flowering. Large examples that have become leafless in the centre should be broken up and each piece given a separate pot. In this way a young, healthy stock is maintained. Plants that are in a thriving condition, and require additional root space, may be moved on without much root disturbance. Pots or pans without side holes may be used, and both should be filled to one-half of their depth with drainage. The rooting material consists of *Osmunda-fibre*, peat, and *Sphagnum Moss* in equal parts, cutting the whole moderately fine, and after removing all the fine particles add a fair sprinkling of crushed crocks. Hard potting must be avoided, but the soil ought to be made sufficiently firm to keep the plant in position. When the repotting

may be done, using a mixture of the best fibrous loam and *Osmunda fibre* in equal parts. A moderate sprinkling of crushed crocks may be added. Ordinary flower-pots are chosen, these being filled to one-third of their depth with drainage. For a few weeks after potting, careful watering must be the rule, but once root action is evident the supply can be increased. This *Zygopetalum* must be treated liberally, and when the pots are filled with roots occasional supplies of liquid manure are beneficial. *Z. Mackayi* is readily raised from seed, which may be sown around the base of an old plant directly it is ripe. Germination soon begins if the compost is kept moist.—SADOX.

VEGETABLES.

NOTES AND REPLIES.

A weedy Asparagus bed.—How can Bindweed in an Asparagus bed be best destroyed without injury to the roots amongst which it has taken hold? The beds appear to require more soil on them, the surface is hard and has worn thin. What should I add—sand from sandhills near the sea, ashes from the rubbish-heap, manure from the fowl-yard? All the above are available, and in the winter burnt Seaweed.—N. MATTHEWS.

[It is of no use attempting to clean an Asparagus-bed so foul as yours evidently is. The best thing you can do is to lift the roots when the foliage has died down and force them, then throw away the roots; or, better still, burn them so as to get rid of the Bindweed. You should then, next March, purchase strong two-year-old roots and plant in soil which you should, in the autumn, have well dug and manured as soon as you have a piece of ground empty. If these roots are well attended to in the way of feeding you will have good heads the second year after planting. Do not cut any of the heads the first year after planting. On no account plant on the ground on which your present Asparagus is growing.]

Ridge Cucumbers.—Many amateurs who would like to grow Cucumbers are deterred from doing so by the fact that they do not possess a frame. For such, Ridge Cucumbers are especially valuable, as they require no glass at any stage of their growth. A simple way to raise a plant or two is to make a hole in a sunny border about a foot deep, and in this to place a moderately-sized lime shell, afterwards returning the soil. On the top of this soil sow the seeds about $\frac{1}{4}$ inch deep, the heat generated by the slaking lime being sufficient to give the young plants a good start. With the summer heat, growth will be rapid, and the details of culture are very much those which are needed by Vegetable Marrows.—KIRK.

Vegetable garden.—Any available material may now be used for mulching. Lettuces, Cauliflowers, Peas, and Globe Artichokes appreciate a mulch in dry weather. If material is scarce for this purpose, let the flat hoe be kept at work among the crops. Should the dolphin-fly make an appearance among Broad Beans, pinch out the tops of the plants without delay. There is yet time to sow French Beans. Such a sowing sometimes saves the situation at the end of the season, although at other times it is destroyed by frosts before the pods are available. An eye should be given to recently-put-out Brassicas, and any blanks made good without delay. If Celery needs watering, time is well spent in attending to its requirements, but, so far, no artificial watering has this season been needed in this district.—KIRK.

Carrots in frames.—The culture of Carrots in frames has begun at an earlier date than usual. Owing to indifferent germination in the case of maincrop varieties the lines are rather gappy, and as, in addition, there is the risk,

Part of a group of the Moccasin-flower (Cypripedium spectabile) at Lilford Hall, Oundle.

Water is afforded copiously in dry weather, and the bed given a dressing of leaf-soil and decayed manure each winter.

F. W. G.

Lilford Gardens, Northants.

MASDEVALLIA TOVARENSIS.

In this the flowers are pure white, and of a moderate size, two and three being produced on one stem. If the flowers are not cut, but permitted to decay naturally, the stems will continue green and fresh. These should remain on the plant, when flowers will again be produced at the apex of the stalk. This may even be continued for a third year, but all good Orchid growers refrain from taxing the plant to this extent. *M. tovarensis* should be grown at the warmest end of the cool or *Odontoglossum*-house, where plenty of air is admitted, and shade from the direct rays of the sun be afforded from March till October. During the winter a few of the *Masdevallias*, including the subject of this note, are removed to the intermediate-house, where the tempera-

is completed water must be afforded very carefully, an excess in this direction causing considerable loss of foliage. In a few weeks the plants will root freely; then water can be given more liberally and the atmosphere may be kept moist. If any slugs are in the house they will probably find *M. tovarensis*, and every effort should be made to trap these pests.

W. B.

NOTES AND REPLIES.

Zygopetalum Mackayi.—This desirable *Zygopetalum* was introduced from Brazil in 1826 by Mr. Mackay, of the Trinity College Botanic Garden at Dublin. The orthodox Orchid-house is not necessary for the successful cultivation of this species, very fine examples being often seen growing in a stove or warm greenhouse. The flowers, which are light yellowish-green marked with purplish-brown, the lips broad, white, and streaked with violet-purple, are produced during the autumn and winter. A few weeks after the scapes are removed any repotting

always present in these gardens, of losses by the attacks of fly, it has been considered quite as profitable to make a sowing in frames as out of doors. The variety used is Early Scarlet Nantes, a stump-rooted Carrot of some merit, and which is fit for use in a comparatively short time. The seed was sown on a spent hot-bed to which was added a couple of barrow-loads of light, sandy soil with the admixture of a proportion of wood ashes. The sashes, after sowing was completed, were returned to the frames, and mats will be used for shading until germination takes place, when, after the seedlings have been gradually inured to the outside temperature, they will be entirely removed.

Hick's Hardy White Cos Lettuce.—This old Lettuce of the Cos type still maintains its popularity. This Lettuce, which so many gardeners have known for many years under the above name, has been made familiar under other names. Whatever name it may appear under it is a good Lettuce for autumn sowing, and usually can be depended on to stand the winter. I have now (the last week in June) just finished cutting fine, crisp heads. The seeds were sown in September on a plot cleared of Potatoes, the seedlings being allowed to stand in the seed-bed until February, when they were transplanted to ground to be occupied later with Brussels Sprouts. It is found, however, that Lettuces deprive the soil of much of its fertility, and I intend giving a little surface dressing of burnt refuse, if nothing better can be found. There is, however, great value in freshly made "burn-bake."—W. STRUGNELL.

Celery.—The earliest plants are now sufficiently advanced for blanching. The most economical and simplest method of effecting this is to use strips of brown paper. In the case of early Celery especially it has many advantages over that of banking the plants up with soil. The blanching is more perfectly done, the stems are not liable to be injured by worms or slugs, and the plants can be fed and watered much in the same way as if blanching was not being done. Give the plants a thorough soaking of water at the roots, and in the middle of the day, when the leaves are dry, proceed to place the paper round each plant. The bands should be cut about 5 inches in width, and should be fastened securely, but not too tightly, round the bottom of the plant. A small quantity of fine soil should be placed round the base. In eight or ten days a further band should be added to the plant, the process being continued until a sufficient depth of blanching is secured.

Spring Cabbage.—This is one of the most important crops in the vegetable garden. I make two sowings—one during the second week in July and the other about a fortnight later. The bed on which the seeds are to be sown should be fully exposed to light and air, so that hard, short-jointed plants may be obtained. When the soil has been dug and made level it should be trodden lightly, and shallow drills drawn at 1 foot apart. The seeds should then be sown thinly, so that no crowding of the young plants may take place. A net should be placed over the bed as a protection from birds. As soon as the young plants appear a careful watch must be kept for slugs, which may be readily destroyed by dusting the bed with hot lime early in the morning. Favourite varieties are Harbinger, Flower of Spring, and Ellam's Early.—G.

French Beans.—These are always useful in autumn after Scarlet Runners are either over or the pods get tough. A few rows sown on a south border at this date can generally be depended on to yield good gatherings of succulent pods at the time stated. When they come into bearing provision can also be made, if weather conditions are unfavourable or frosts threaten, to protect them at night either with mats or canvas covers.

Spinach Beet.—Showery weather has provided ideal conditions for the thinning and transplanting of the surplus plants. Another sowing should be made now and a similar one about the same date in August for spring supply. This should always be grown wherever there is a difficulty in preserving true Spinach during the winter, as it is perfectly hardy and leaves nothing to be desired in the way of leaf production.

GARDEN FOOD.

DRIED FRUITS THE YEAR ROUND.

THE greater the amount of fruit one eats the nearer he comes to an ideal diet. There is no question about the hygienic value of fruit. Year by year people are consuming larger quantities of fresh fruit, and it is no longer considered a luxury or an occasional addition to a meal, but takes a prominent place in the planned menu. Dried fruits, while not so luscious, have far greater nourishing value than fresh fruits—three times as great. Fruits are largely water and carbohydrates, but in the case of the dried or evaporated fruits, the water has been removed and only the bulky and nutritious portion remains. In the case of evaporated Apples, Peaches, Pears, and Apricots, it is only necessary to soak them sufficiently long for them to re-absorb the original amount of water. They then have practically the consistency and value of the fresh fruit, although the process has changed the taste quality. From an economical point of view, thrifty housekeepers use the evaporated fruits in the making of desserts and as sauces. The laxative property of these fruits is of more value than that of the fresh fruits. The one great objection to the use of the dried fruits as sauces is that too much sugar is added to the fruit in cooking. The natural fruit sugar is digestible and is the normal sugar needed by the body—it is invert sugar. Cane, corn, and beet sugars have to undergo changes in the process of digestion before they can be utilised by the body. Wash thoroughly in boiling water all dried fruits before preparing them for the table. Such foods should be soaked for five minutes in a 5 per cent. solution of hydrogen peroxide. Many housekeepers do not realise that the juice from cooked dried fruits is a very palatable beverage, and with the addition of a little Lemon-juice will make a pleasing variety of fruit beverages. The craving for sweets in grown-ups, as well as in children, may be satisfied by dried fruits, because the fruit sugar answers the natural physiologic demand for sweets, and without the injury that accompanies the consumption of ordinary sugar foods. Many of the objections to pastry and sweets will be removed if more fruits are used in their preparation to the exclusion of sugar.

PRUNES.—Of all the dried fruits, the Prune is probably the one most generally used. There is no part of the world where Prunes are not used the year round, and in many families where hygienic diet amounts to a religion Prunes in some form appear at every meal. The Prune is one of the most laxative of foods, and the juice when boiled down to the consistency of syrup, without the addition of sugar, is a cathartic. Many people eat raw Prunes, after they have been soaked until they have absorbed all the water possible.

FIGS.—Figs are also both food and medicine, and should be used much more freely than they are. To some people the seeds are irritating, and in that case strained Fig syrup may be used on cereals or in any preferred way. By soaking dried Figs overnight they can be made almost like fresh Figs. It is better, however, to steam or stew Figs before eating them. A quantity of Figs can be steamed and then used when convenient.

DATES.—Dates also have a laxative tendency, and contain almost half their weight in sugar. Like Prunes and Figs, Dates are not only a concentrated food but combine the medicinal, laxative qualities with their nourishing properties.

There are two special classes of Dates, the soft and the dry. The dry Dates are moderately sweet and have a very delicate flavour. One can make a meal of dry Dates without being cloyed by them, while one can only eat a few of the very sweet, soft Dates that are found in our markets. Our Dates are eaten more as a dessert. The dry Dates in the Sahara are one of the principal foods of the people, and to a large extent take the place of bread.

CALIFORNIA RAISINS.—Formerly, Raisins were not used so extensively in the United States as they are at the present time. They were used as dessert, and with Nuts, and eaten occasionally out of hand, but now they are esteemed as one of the most valuable of the dried fruits, and when stewed or steamed make a most delicious sauce. Cooked Raisins are particularly good for growing children, and the child who will refuse Raisins in any form is probably not to be found. Since she can buy seedless Raisins, much labour is saved the housekeeper. There are no more delicious Raisins than are produced in California. This luscious fruit can be purchased in large or small packages, and comes clean to the consumer. It is well, always, to purchase dried fruits in small packages and not in bulk, because the sticky surfaces furnish a favourable lodging place for dust and germs of all kinds. Where fruits stand open in shops they are always unclean. Even the package fruits should be given the hot bath before being put to soak.

It is possible for one to live in full health and vigour for long periods when subsisting on a diet of dried fruits, Nuts, and a few grains and some of the fresh fruits. It is the dried fruits that furnish the bulk of the nourishment of fruitarians. In the summer, when both dried fruits and fresh fruits of all kinds are in the market, even those who are meat eaters in cold weather can plan a healthful and satisfying menu without flesh foods.—*Good Health.*

NOTES AND REPLIES.

Spoiling the Peas.—The following I find in a popular journal:—

Having melted 2 oz. of margarine in a covered fire-proof pot, add four breakfast-cups of shelled Peas, two young Lettuces shredded, half a teaspoonful each of sugar and chopped Mint, salt and pepper to taste, with two spring Onions and a sprig of Parsley. Cook over a moderate heat till done. Then dish the Peas, pour over them the liquor thickened with a roux of butter and flour, and garnish with sippets of toast or fried bread, or with crisp rolls of bacon.

[British Peas want no such ignorant aids. They are better without any of the things named.—ED.]

Turkish coffee is easy to make in an Etna. Boil the water with sugar. When it boils lift it off the spirit stand and throw in the coffee, as finely ground as possible. Then, with a spoon, stir vigorously to incorporate it evenly in the water, and replace over the flame as quickly as possible. It will almost immediately come to the boil again, and you must take care that it does not overflow. Lift it off for ten or twelve seconds, then put it on and bring it to a second boil. Lift it off again and put back, bringing to a third boil. Then put out the spirit lamp. Now, with a teaspoon, skim off the *kaimak* and put a spoonful of it into each cup. Fill up the cups with the liquid and there you are. You may remember that this coffee is drunk very sweet, but it is said to be far more wholesome than any other way. Ordinary coffee is a sealed book to the average English cook. They cannot make it at all.—J.

OUTDOOR PLANTS.

**A ROCK SNAPDRAGON
(ANTIRRHINUM ASARINA.)**

This plant, which I have known for long years lying about the mixed border, generally in a miserable state, and looking of very doubtful value, I saw in rather a noble way in the rock garden at Friar Park, just depending between two great rocks. This is the usual form of it. In the same place there were several others, including a bicolor form, showing that the plant is a really first-rate rock plant if given a good place. W.

HARDY FLOWER NOTES.

THE GOAT'S BEARD (Spiraea Aruncus).—The full value of this species can never be

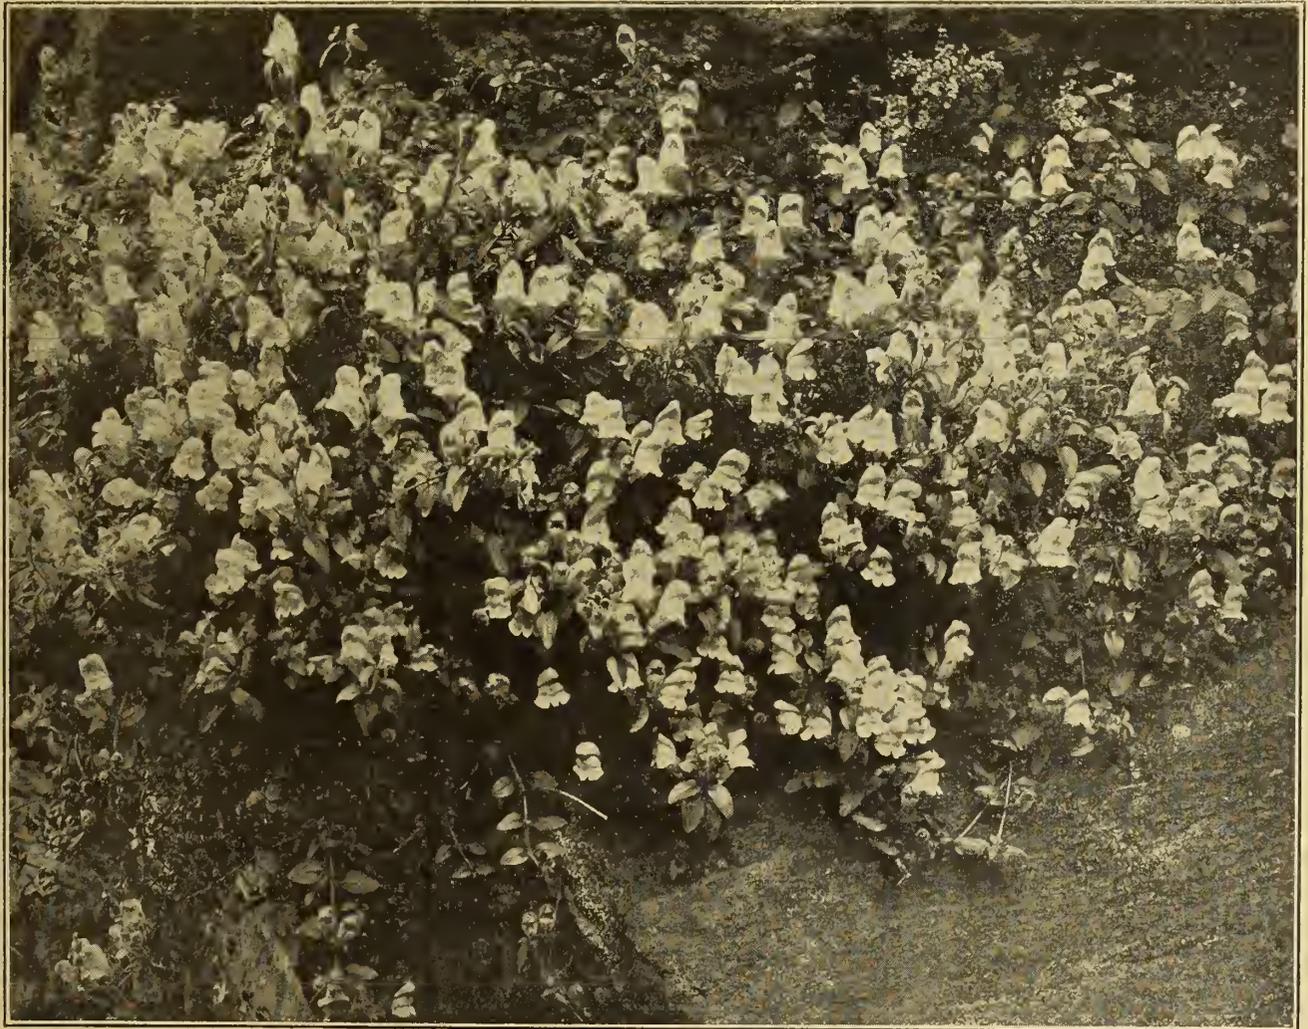

time that plant will be in healthy vigour. It is growing in soil that never gets manure.

GENTIANA VERNA IN THE GRASS.—With respect to "W.'s" note (p. 342) I distinctly stated that it was never likely to thrive in long Grass, and I also stated that it was a success in thin Grass at Wisley. I saw the plants, and they were in perfect health, and I also witnessed various failures when they were planted under different circumstances.

SALVIA TENOREANA has been very effective this season, and, like the *Spiraea* above mentioned, it requires space, and will last for some years in good condition without disturbance if it gets plenty of light, air, and sunshine, without which it will be more or less a failure. Fully ex-

and a portion worked through between the plate and the wall forming a patch about a foot square. I was surprised to note the vivid colouring of this Thyme. Thus situated, it was certainly very fine and very different from what it had been hitherto. Those who need wall plants should make a note of this Thyme.

OXALIS FLORIBUNDA.—I am told that in some places this will not take on permanent vigour. A skilful grower of hardy plants says that it will not last more than a couple of years with him, whereas with me it grows in weed-like fashion and has, in fact, become thoroughly naturalised, springing up all over the place, but always, with a kind of instinct, in situations favourable to its well being. It loves a well-drained position, and does not mind

A rock Snapdragon (Antirrhinum Asarina) in the rock garden at Friar Park.

realised where it is crowded up with other things. It requires a certain amount of isolation and good, well-stirred ground. Although the growth of this *Spiraea* is compact it is saved from formality by the much-divided foliage. In planting this *Spiraea* consideration should be given to the fact that it is one of those things that are best grown on the let alone principle, therefore a position should be chosen which can be occupied by it indefinitely, with space for development, and by reason of its inherent vigour it will thrive and increase in blooming power where other members of the family would fail. I have a specimen some ten years old which is about 6 feet high and as much across, and which this year carried fifty or more fine flower-heads. I believe that in ten years'

posed and in well-drained soil it has a much higher decorative value than when closely surrounded by tall-growing things, where it has a loose, weedy appearance and the flowers are much paler. The free-branching habit is only displayed when it gets a certain amount of isolation.

THE BRIGHT-FLOWERED THYME.—One may grow a hardy plant for some years, and through not being placed in a favourable position or not getting a suitable rooting medium it fails to come up to expectation. The terms *ruber* and *coccineus* are too often applied without good reason, and although I have had the variety of Thyme named *coccineus* for some years, until this season I could never see that this term was well applied. I have had it on a mound close to a row of frames

how hot and dry it may be. In one place, in front of some old *Yuccas* and where the soil is extremely poor and dust dry for weeks together, there is a group of the typical form, which, surrounded by the white variety, is very effective in the bright sunshine. It is curious that where this species refuses to take on permanent vigour that beautiful kind, *O. eucnaphylla*, flourishes, whereas with me it dies away. This is one more instance of the eccentricities of some hardy plants.

MORINA LONGIFOLIA.—Some hardy plants are almost worthless unless they are thoroughly well grown, and this *Morina* is one of them. In poor soils that parch in summer it has no value, but under good culture it is very attractive and is very distinct. In a soil of medium texture and

where there is a certain amount of moisture in summer it will throw up flower-stems from 2 feet to 3 feet high, the Thistle-like growth and the parti-coloured whorls of bloom being very effective. In the enjoyment of perfect health this *Morina* is decidedly a handsome and attractive hardy plant. J. CORNHILL.

THE BELLFLOWERS.

The majority of the many varieties of *Campanula* will soon be at their best, and, whether tall, medium, or dwarf, they rank, so far as the whites are concerned, among the purest of hardy flowers. The note in a recent number as to the rather miffy habit of the double form of *C. persicifolia* many growers will doubtless agree with, one seldom finding it in a thoroughly thriving condition. It likes a fairly rich, open soil, and pays for annual lifting and replanting, doing this directly after flowering.

A colony of Bellflowers in variety is a most interesting feature of a garden, a likely spot being a slightly sloping border in a partially shaded position, a frontal arrangement of occasional stones some 2 feet or 3 feet in depth affording opportunity to show off the dwarfest kinds like

be included if space permits, but I should hardly recommend them. They make a very attractive display during the comparatively brief time they are in flower, but the somewhat thick, heavy appearance seems hardly in keeping with the graceful character of the majority of the perennial forms. E. B. S.

Hardwick.

A WATER LILY GROWN IN CALIFORNIA.

For the lover of Nature and the plant enthusiast, life in California is almost a perpetual holiday. I have a fair-sized garden and grow an enormous number of good plants besides the Water Lilies. I take a very great interest in our native flora and have a collection of the plants growing in my garden. Water Lilies do well here and the period of blooming here is longer than in the Eastern States. Just now I am enjoying greatly *N. Mariacea*, *N. Mrs. Richmond*, *N. virginialis*, and *N. Escarboucle*. I have a hybrid of my own which has flowers of a rich deep pink with carmine shadows between the petals, and the rich fragrance of *Nymphaea odorata*. The rhizome is of the *N. candidissima* type. It is very

of 6 inches. I replanted them in good leaf-mould, but they have not yet shown above the ground. This is quite five weeks ago. I followed the instructions given in *GARDENING ILLUSTRATED* for 1880, but, of course, the deep planting was the gardener's mistake. Can you advise me? Should the tubers be left or would it be better to take them up?—K.

[Seedling *Alstrœmerias* make but little top, i.e., stem and leaf growth, in their early years, and doubtless the little that was made—if, in the circumstances, made at all—quickly perished, owing to the great depth at which the tubers were planted. The depth was, of course, a mistake, 6 inches or 8 inches being ample to ensure safety. You say the tubers, when lifted, were quite healthy, and, if so, there should also have been the evidence of a crown bud to each plant, but of this you say nothing. As the season of growth in these plants is now past, no further development in that direction is likely this year, but if all is well, a few inches of growth should appear next year, though not sufficiently strong for flowering. You erred in your haste to plant out such small seedlings, which would have made more rapid progress had they been transplanted and grown in boxes or pans for a year longer. As you appear convinced of their healthy condition, and as no growth would now ensue, even though you lifted the plants, they had better remain where they are, covering the bed with a few inches of litter or leaf-mould in the event of severe frost during the ensuing winter. We regret this reply, owing to pressure on space, has been unavoidably held over.]

A handsome hybrid *Primula*.—A very handsome hybrid *Primula* has appeared in Sir Herbert Maxwell's garden at Monreith. It is believed to be a cross between *Primula Bulleyana* and *P. japonica* or *P. pulverulenta*, probably *japonica*. It is more ornamental than even the beautiful hybrids sent out by Messrs. Bees, its beauty being increased by its taller stature. In this it comes between *P. Bulleyana* and *P. japonica*. It bears handsome whorls of flowers of a kind of buff with a touch of scarlet about them. It has seeded at Monreith, but it remains to be seen whether the seedlings will be like their parent or will revert to either of the species whence it has sprung. This *Primula* is distinct from any other hybrid I have seen, and Sir Herbert Maxwell is of the same opinion.—S. ARNOTT.

Michaelmas Daisies.—These are now being thinned out, and the growths retained staked out before they come to grief from rough winds. All the stronger-growing kinds are reduced to five growths each, the four outer ones being staked to lean away from the central one. Grown in this manner, a magnificent display of flowers results in autumn, and each plant is several feet through. When the staking is completed a dressing of an approved fertiliser will be given and hoed in.

Papaver umbrosum.—Twenty years or so ago I purchased a packet of seed of the annual *Papaver umbrosum*, and with the exception of a year or two after a severe frost in the spring I have never failed to enjoy an annual succession of its flowers. In a year or two, however, after I lost it, fresh plants appeared from seeds turned up in cultivating the ground, and again I have this Poppy, though in much smaller numbers. Its nominal height is about 18 inches, but it varies according to the soil.—S. ARNOTT.

Primula Beesiana in moisture.—At the margin of the little Water Lily pond in my garden *Primula Beesiana* is now in fine bloom. It is planted on a "shelf" of concrete which is below the surface-level of the pond, and in soil which rises about 9 inches above the water. Here, with plenty of moisture all the year round, this *Primula* thrives and flowers very freely. *P. Bulleyana*, *P. involucrata*, *P. farinosa*, *P. japonica*, and others thrive in a similar place.—S. ARNOTT.

Antirrhinum Asarina, bicolor form. (See page 373).

C. fragilis, *C. pulla*, and *C. pusilla* to the best advantage, from these working through with those of medium height and finishing up in the background with the giants of the family, like *C. lactiflora*, *C. latifolia macrantha*, and *C. pyramidalis*. There should be an endeavour so to distribute the different varieties that no considerable portion of the colony should be without flower at any time through the season. The only members of the family that do not appeal to me are the varieties of *C. glomerata*, the dense terminal heads being so different from the thin, wiry stems and graceful bells of other sorts. However, a clump or two of *C. g. dalurica* might be included in the collection, as it supplies the deep purple shade in that particular height. It may be noted in connection with the site recommended that partially sloping ground affording natural drainage is the best position for those members of the family like the double Peach-leaved, which, although liking a fairly rich soil, are decidedly averse to any situation from which the water does not pass quickly. The partially shaded position helps to a prolongation of the flowering season and prevents scorching of the more delicate shades.

The biennials, that is, the many varieties of *C. Medium* in different shades, may

be beautiful, but such a shy bloomer that I have never placed it on the market. I think it would do better in a lake with a natural earth bottom and a free run. I would like to learn how it would behave in England and would be pleased to send you a root for trial. I grow quite a number of semi-aquatic Irises, among them *I. hexagona La Mancei*, or, as it seems to be now called, *I. foliosa*. This is very beautiful, but would not bloom freely with me until I plunged the receptacle in which it was growing in water up to near the surface of the soil.

EDMUND D. STURTEVANT.
Hollywood, California.

NOTES AND REPLIES.

Alstrœmeria seedlings.—Can you help me in the following difficulty? In the spring of last year I raised some strong seedlings of a rose-coloured *Alstrœmeria* we have. After hardening them off, I placed them out-of-doors in July, and planted them out last October in a sheltered position. A small frame was placed over them and removed when the weather this year was warm enough. No plants appearing, I had the soil removed from the place where they had been planted. After clearing it off for about 1½ feet deep, I found the tubers perfectly healthy and sound, but no buds. I found the gardener had planted them a foot and a half deep, instead

TREES AND SHRUBS.

LONICERA ALBERTI.

THIS rather rare Honeysuckle belongs to the bush section of the family. It grows from 3 feet to 4 feet high and is made up

A flowering shoot of Lonicera Alberti.

of many slender, interlaced branches clothed with small, narrow leaves, and bears, during May or early June, small, pinkish, flowers in pairs from the leaf-axils. It is a native of Turkestan, and has been grown in this country for about thirty years. The illustration accompanying this note gives an idea of the manner in which the flowers are produced, and it will be seen that they appear from almost all the leaf-bases at the bottom of the current season's shoots. Like other members of the family it requires good loamy soil, which is constantly moist and cool without being waterlogged. A sunny position is desirable, for thorough ripening of the previous year's wood is essential to the production of flowers. Pruning is unnecessary, in fact the bush Honeysuckles are often spoiled by pruning. Cuttings root easily when inserted in sandy soil during summer, and soon grow into serviceable plants. D.

AZALEAS NOT FLOWERING.

COULD you tell me how to treat Azaleas which have been neglected for many years? They are growing in a glade on a south bank of peat and sandy loam, and the garden is 1,200 feet above sea-level, on the moors, about 7 miles out of Sheffield. They seem to like the position and the soil very much, but I believe they were put in many years ago (say, about fifteen), and I am sure something ought to be done for them. They have grown very straggly, and some bushes have had scarcely any blooms on them at all, though they are full of leaf. I also think they ought to be thinned and transplanted. I should be very much obliged for any information you can give me on the subject of outdoor-grown Azaleas and the best way of propagating them.—Mrs. M. D. MORSE.

[Your Azaleas are evidently suffering from lack of nourishment, which may be made up to them in the shape of a good top-dressing. It is also probable that they have been at times too dry at the roots. A good plan to renovate them will be to lightly fork over the surface of the bed and top-dress to a depth of 4 inches to

6 inches with a compost made up of loam, cow-manure, and leaf-mould in equal parts, the whole being thoroughly incorporated together. Though winter is usually looked upon as the most suitable time of the year for this, we should, in view of the fact that your plants are gradually getting worse, carry out the operation without delay. It is very probable that on examining the soil you will find it desirable to give a good watering and allow it time to soak in before applying the top-dressing. With regard to cutting back the straggling branches you must bear in mind that the old bare wood does not break very readily. This, however, may be done in moderation. The question whether they ought to be transplanted can only be answered by one who can see the plants, their condition, and surroundings. Provided the soil and other conditions are suitable, Azaleas give but little trouble. A fair amount of moisture at the roots, not stagnant water, is very necessary, and as soon as the blossoms are over, all old seed-pods should be picked off, and any straggling shoots shortened back.

The propagation of these Azaleas is, in the case of named varieties, usually done in nurseries by grafting, a very delicate operation. They may also be increased by layers, which will take about three years to be sufficiently rooted to detach them from the parent plant. Layers are best put down during the dormant season. Azaleas can, however, be readily increased by seeds, and although this method cannot be relied upon to perpetuate any particular variety, superior kinds often result therefrom. What is more, seedlings, as a rule, form more shapely specimens than grafted plants. The seed may be sown as soon as ripe in some light, suitable soil. The seeds, being very minute, are best sown in well-drained pans and stood in a cold frame. A little fine sandy soil will be all the covering needed. The compost must be kept moist and the frame close and shaded till germination takes place, when more air should be given. When large enough, the young plants should be pricked off, and, after a time, planted out. The only book bearing on the subject, that we know of, is "Rhododendrons and Azaleas," by William Watson, price 1s. 6d., through any bookseller.]

TREES AND SHRUBS AT ALDENHAM.

CRATÆGO-MESPILUS JULES D'ASNIERES.—This has been so covered with vivid white blossom that no foliage can be seen. It is, I think, more showy than any pure Cratægus, and certainly holds its flowers longer. It is a more beautiful tree than that other graft hybrid between Thorn and Medlar, Cratægo-mespilus Dardari, which, as many readers know, sprang originally from the same tree in a French nursery.

CORNUS BRACHYPODA, or, rather, *C. controversa*, as I believe we ought now to call it, is usually seen as a straggling bush, but I have pruned off the lower branches of the plant and have obtained a clean, straight stem of about 5 feet high, with a head of broad, flat branches loaded with white, Elder-like, upright-standing corymbs; the effect is very pleasing, and no one comes here without his attention being immediately attracted to it.

THE SYRINGAS, OR LILACS, are practically over, but some of Wilson's introductions, which have got old enough to flower freely this May, are quite worth growing. The best, in my judgment, is *S. reflexa*, with real rose-red, not purple-red flowers. *S. Wilsoni* (flowers white) is

already 10 feet to 12 feet high. *S. Sweginzowi*, though it was honoured with an Award of Merit when I exhibited it last year, is not, to my thinking, as good as either the old Persian Lilac or as the much less common *S. Juliana*, which was quite charming when in pale lilac flower a fortnight ago.

LONICERA CILIOSA.—Among creeping or climbing plants now in flower this is by far the most gorgeous, with deep orange clusters; a quite hardy plant which has been long ago introduced, and which flourishes in any decent soil and climate, but which is far too seldom seen. If this be just now our showiest climbing plant, I think the most interesting is

ARISTOLOCHIA HETEROPHYLLA, whose foliage is very much smaller and more refined than in the better known *A. Siphon*, and its chocolate-white flowers even more closely resemble those of the "Dutchman's Pipe."—VICARY GIBBS, in *Irish Gardening*.

OLEARIA MYRSINOIDES, VAR. ERUBESCENS.

FROM the general appearance of this shrub one might well question its right to close association with *Olearia myrsinoides*, for it is distinct from that species in its more vigorous growth, much larger leaves, and larger heads of flowers. *O. myrsinoides* is a loose-habited evergreen bush 3 feet or more high, with small, narrow leaves and flower-heads 1 inch across, borne singly from leaf-axils of the previous year's wood, during May and early June. The variety *erubescens*, on the other hand, has leaves each up to 3 inches long and 1 inch wide, which are more attractive than those of the species, the upper surface dark green and the under surface silvery. Moreover, the flower heads are larger and borne in clusters from the leaf-axils, a well-flowered branch being a decidedly

Part of a plant of Olearia myrsinoides erubescens on a wall in the Royal Gardens, Kew.

pretty object. It is a native of New Zealand and is hardy in the milder parts of this country. Elsewhere the protection of a wall should be provided. It is easily increased from cuttings of half-ripe shoots inserted in light soil in a close frame in summer. D.

NOTES AND REPLIES.

Silver Firs dying.—I enclose two pieces of a Silver Fir. Can you let me know what is the matter? I have had several trees go the same way—losing their tops altogether and dying.—H. LEWIS HAMMOND.

[The Silver Fir attacked by *Chermes abietis*. This insect, which is related to the green flies, passes part of its life on the Silver Fir, part on the Larch, feeding on the latter in summer, where it may be seen forming little patches of white on the needles through the waxy tufts that cover its body, and passing later to the Fir, where its presence sets up irritation, leading to the production of the galls which you see on the branches of the latter. The best place to attack the pest is on the Larch, where it may be destroyed by spraying with any of the more reliable washes used for aphides, and especially by paraffin emulsion or a nicotine wash.]

The poisonous Yew.—Please do not insert any more notes about the Yew on both or any side of the question. For people to sit on a fence on a matter of this sort is absurd. The tree is deadly for stock in all states, and if a record could be made of its destructiveness it would amaze people. I believe that many deaths of animals are wrongly attributed to other causes. The ignorance of gardeners about it is amazing. Worse still, that of the pretended landscape gardeners, who scatter it liberally about, even near the approaches to the house, where the poor horses can scarcely miss it. Every scrap of it in hedgerows should be cut out and burnt. I have lately done this in my own place. Hair-splittings as to whether male or female Yews or whether dried clippings or fresh shoots are the more deadly are a danger, as there is evidence that all are deadly. There is no need to have the tree where stock can touch it. Its place is in enclosed grounds, graveyards, and in the heart of woodland. A great source of danger is leaving the lower boughs, often old and wasting away, on the Yew-trees. I cut these away to a height of 12 feet or 15 feet, and the trees are all the better for it. The effect is many times better, as the lower and worn-out boughs often hide the stem of one of the most beautiful of our native trees. In some woods the Yew sows itself. These woods should be gone through and the lower branches of any Yews cut off. Then if cattle break through they come to no harm through the clean-stemmed trees. When this trimming is done light a fire near and burn every bit of the shoots.—W.

Escallonia langleyensis.—During June and July this is one of the most effective flowering shrubs, for during those months it is covered with rich, rosy-carmine blooms, and even later numerous inflorescences may be found. It is one of the hardiest of the *Escallonias*, being next in hardness to *E. Philippiana*, which, by the way, is one of the parents of *E. langleyensis*, the other parent being the evergreen *E. punctata*. The plant was raised by Messrs. Veitch at Langley rather more than twenty years ago and soon became popular as a trellis plant, its long, slender branchlets peculiarly fitting it for such a purpose. It also forms an excellent bush, as may be seen at Kew by two large masses growing behind the Palm-house. About twelve years ago two beds were planted with small plants, and in each case they have grown together, forming handsome masses 8 feet to 10 feet high and 20 feet across. The leaves are usually retained throughout the winter, but in the event of cold weather being experienced they may be deciduous, though the wood is not injured except in extreme frost.

The flowers, each about $\frac{1}{2}$ inch across, are borne with the greatest freedom in short racemes from the points of short growths. It grows well in ordinary garden soil and is easily increased from cuttings of soft shoots inserted in sandy soil in a warm frame in July. Plants grown against trellises require thinning after flowering, but bushes grown in the open do not need regular pruning.—D.

FRUIT.

GRAPE CULTURE.

I HAVE been much interested in the notes on "Grape Culture," by "Byfleet" and "W. McGuffog." I once heard a gardener say "he would rather renovate old Vines than plant young ones." As I have had some considerable experience of the planting of young, and the renovation of old, Vines during the past thirty-five years, perhaps a few notes on such experience may be interesting. Given my choice I would rather plant young Vines than restore old ones, if I could do as I wished in the matter of border formation, etc. I am sure that many cultivators fail with young Vines through overcropping during the first four or five years. I like to build up Vines gradually, and in doing this I prefer to have restricted border space, making up the border piecemeal, and not having a greater depth than 3 feet.

With regard to old Vines, when I took charge of one large garden the Vines had been condemned and preparations made for planting young ones. I decided to renovate the Vines in three houses and plant young ones in the fourth. One house contained Muscats. The annual shoots made were moderate only in strength, but one of our noted Grape growers, when paying me a visit, said he should never again believe it to be absolutely necessary to produce very strong wood on Muscats in order to secure fine bunches and berries. The first year I cropped rather lightly, then more heavily. Several persons told me the crop was too heavy and that I should not have any good Grapes the following year, but for ten years the crops were, each succeeding year, more satisfactory, and I left them so. These Vines had been brought to a bad state through a too high temperature and moist atmosphere, and continual syringings throughout the summer and insufficient air. I never syringed after the young shoots were 1 inch long, and grew them more hardily, admitting air freely in due season. The borders were surface-mulched and then covered with whole turves, Grass sides downwards, and under these a network of roots formed. Old rods were gradually cut out and young ones retained in their place. G. G. B.

SHORTNESS OF THE PLUM CROP.

It would seem, judging from reports from growers in various districts, that the Plum crop of 1916 is much below the average. Plums everywhere blossomed profusely, and hopes were entertained that the setting of the crop was assured. Such hopes were, however, dashed to the ground, as the young fruits began to fall freely, until at length very few remain. Some kinds are absolutely barren, while others have but a light sprinkling. Perhaps the only exceptions are the old and popular Victoria and Czar, the latter carrying a full crop. Early Rivers', or Rivers' Prolific as it is known to some, rarely fails, but this year on many trees there is no fruit while others have but a sprinkling. On wall-trained trees the prospects are but little better.

There is, as everyone knows, a great dearth of bees this year, due to the disease which has played such havoc with them, and it may be their absence to some extent accounts for this dearth of Plums. There are, I believe, in some districts, a fair crop. It is very unusual for open-air and wall-grown trees to exhibit such sterility. The weather was wet and cold, as it usually is in Plum-blossoming time, but there was no frost. Damsons are similarly short. Out of several trees I have, only one has a crop, and that very light. Others, mostly standards, have not a sign of fruit on them. It would be interesting to learn from some among your many correspondents scattered over the country whether this Plum shortage is universal or only local.

W. STRUGNELL.

Trowbridge, Wilts.

NOTES AND REPLIES.

Silver-leaf on Plum-tree.—Can you tell me what treatment to adopt for the blighted Plum-tree of which I enclose some sprigs? The whole tree appears to be dying. Is the trouble infectious and likely to injure other Plum and Apple trees growing near? The trees are all young standards, but only one has been attacked.—N. MATTHEWS.

[The piece of Plum-tree you send has been attacked by "silver leaf," for which there is no cure. The best plan is to grub and burn the tree. If you intend planting another Plum in its place then you should remove the old soil as there is the probability that the roots of the newly-planted tree will be contaminated with it. If you plant any other tree bearing a stone fruit, then there is no need to clear out the soil, but you must take care to remove every particle of the roots of the Plum-tree, as such, if allowed to remain, will breed fungus as they decay.]

Apple and Pear crops.—One of your correspondents at Chester (p. 317) speaks of these as being a failure this year in his district. Here in my North London garden, where I have a considerable number of trees, both standards and pyramids, the crop of Apples is very promising, most of the trees being loaded with fruit, though Pears are a failure. This latter is not surprising, however, as all the Pear-trees here cropped so heavily last year that a rest this year was necessary to prevent undue strain on the trees. As regards Apples, almost every variety is bearing exceptionally well, especially Devonshire Quarrenden, Allington Pippin, that fine old cooking Apple, Alfriston (which, as a standard, always has a good crop with me), Bramley's Seedling, Blenheim Orange, James Grieve (which seems to be a consistently good bearer), as also Pott's Seedling, Warner's King, and others. Some of the standards are quite old trees, and there are other similar old trees in the gardens around mine. Whether it is that the old trunks furnish abundant chinks for the Codlin moth to pupate in I do not know, but, anyhow, we suffer considerably from this pest, and lose a good part of the crops prematurely. Of course, we ought to wash the trunks and branches with caustic soda in the winter, but it is such a disfigurement to the garden, as the trees are scattered about in various parts, that we prefer to put up with the Codlin moth. The miniature fruits which fall are not wasted, but used for making Apple jelly, for which purpose they are admirable. Bush fruit here is doing very well this year, Gooseberries, Currants, Raspberries, and Loganberries all having heavy crops, though the absence of warm, sunny weather delays their ripening.—N. L.

ROYAL HORTICULTURAL SOCIETY.

JULY 18TH, 1916.

THAN the exhibition brought together on the above-named date nothing finer in the circumstances could have been conceived, all departments being represented. The outstanding feature of the meeting, however, was the magnificent collection of vegetables sent by the Hon. Vicary Gibbs from Aldenham, and certainly nothing so comprehensive or of such high excellence has been seen before. Grapes, too, and Strawberries from Cliveden were grand, the former particularly so. Of Roses there was a great feast, the National Rose Society holding a special exhibition. Among hardy flowers Phloxes were very fine. Orchids were not largely shown, though choice novelties were seen. Several novelties received recognition, nine new Roses being awarded the gold medal.

HERBACEOUS PHLOXES.

Messrs. H. J. Jones, Limited, Lewisham, S.E., staged these very finely, employing a low-placed table of double width, and using a white groundwork and background. Great stands of the leading sorts were imposingly displayed in upwards of fifty varieties. Dr. Charcot (best of the blue shades), Elizabeth Campbell (pink), Antoine Mercier (deep lilac, white eye, very distinct), Le Mahdi, G. A. Stroblin (scarlet), Europe, Meteore, and Evangeline were a few of the more conspicuous.

HARDY FLOWERS.

These were numerous and varied, demonstrating the wealth of such things at this season. Messrs. Blackmore and Langdon, Bath, arranged a floor group of Delphiniums, as Statuaire Rude, Alake, King Bladud (the self-coloured sport from Rev. E. Lascelles), and Mrs. Shirley, a rather effective uauve. The finest thing in a group from Messrs. G. Jackman and Sons, Woking, was a handsome gathering of *Scabiosa caucasica*, a particularly good plant in moderately light soils.

Mr. M. Prichard, Christchurch, arranged a full table of the best hardy flowers, Phloxes, Crinums, Iris Kämpferi, Astilbes, Alstromerias, and others. *Campanula arvensis* (a gem among the choicest alpinas), C. Stansfieldi, and *Genista humifusa* (prostrate golden Broom) were very good. Phloxes, Pentstemons, and Delphiniums were shown by Messrs. John Forbes, Limited, Hawick, Marvel, of the first-named and of violet-blue tone, being very distinct.

CARNATIONS.

Mr. J. Douglas, Great Bookham, exhibited choice border Carnations very finely. We thought Grey Douglas quite a novelty in lavender-grey. In Mrs. A. Brotherston a good freckled fancy was seen. Hereules (maroon) is of large size and very handsome. Elizabeth Shifner, Cecilia (yellow), Bookham White, and Bookham Clove still rank high, and, indeed, are indispensable to any collection.

ALPINES.

Messrs. John Waterer, Sons, and Crisp, Bagshot and Twyford, arranged many choice things in colonies, the best of which included *Gentiana scabra* (very fine blue), the pretty and rare pink Thrift (*Acantholimon venustum*), the charming *Hypericum cuneatum* (scarlet buds and golden blossoms, a most effective plant), *Spiraea digitata nana* (true, its pink-flowered cymes but 8 inches high), and *Tunica Saxifraga flore-pleno*.

Messrs. Thomas Grove and Sons, Sutton Coldfield, showed some of their new hybrid *Campanulas* very effectively. Norman

Grove was very beautiful. Abundance is a taller, paler-flowered companion. Chastity (white) and Meteor (bluish-white) are carpatia forms. A delightfully-flowered mass of *C. Waldsteiniana* (violet-blue), 3 inches high, was also noted. It gained an Award of Merit, as also did Chastity.

Mr. G. Reuthe, Keston, contributed the lovely *Campanula arvensis*, C. Stansfieldi, *Acantholimon venustum*, *Coronilla cappadocica* (golden), *Orchis foliosa* (very fine), and the quaint *Astrantia carniolica*. *Desfontainia spinosa* (tubular flowers in crimson and gold) and *Ononis fruticosa* were good among shrubby subjects.

GREENHOUSE PLANTS.

Messrs. H. B. May and Sons, Edmontou, had quite a notable variety of *Adiantums*, such as Veitchi (with red-tinted fronds), *Faulkneri* and *micropinnulum* (two of the most elegant), with *microphyllum* and *peruvianum*, being noted. In addition, silvery and golden *Gymnogrammas* were a feature, *Mayi* and *flavescens* being the most pronounced of the silvers. Messrs. W. Cutbush and Sons contributed well flowered plants of *Gloriosa rothschildiana* and a group of the new Ivy leaved *Pelargonium Radiance*.

ROSES.

These were in great array everywhere, and we regret our inability to refer to all. In a notable collection from

Mr. J. C. Allgrove, Middle Green, Langley, Rayon d'Or, Lady Hillingdon (richly coloured), British Queen (one of the finest pure whites), and Miss Alice de Rothschild (fine yellow) were among the best. In that from Messrs. Frank Cant and Co. Lady Pirrie (a lovely salmon shade), Mrs. H. Stevens and Mrs. Foley Hobbs (superb whites), and H. E. Richardson (intense velvety maroon, very fragrant) were some of the best. A big basket of Rayon d'Or in Messrs. Hobbies' group was particularly good, the colour glorious. Messrs. B. R. Cant's single shell-pink Cupid was an attraction, Lady Pirrie, Lady Hillingdon, H. V. Machin, Mrs. Foley Hobbs, and the handsome red A. Hartman all being strongly represented. British Queen, Candeur Lyonnaise, George Dickson, and Ophelia were the best in a nice lot from Messrs. Chaplin Brothers, Waltham Cross.

ORCHIDS.

Messrs. Armstrong and Brown, Tunbridge Wells, staged very fine hybrid *Odontoglossums*, also the remarkable *Odontiodas rosefieldensis* (rich orange) and *Bradshawia*, both very telling and distinct. *Miltonia vexillaria Dreadnought* (pink, with white centre) gained an Award of Merit.

Messrs. Charlesworth and Co., Haywards Heath, had the very distinct and rare *Dendrobium acuminatum*, *Laelio-Cattleya Momus* (first-class certificate), together with very fine *Miltonias*, *Odontoglossums*, and *Odontiodas*.

Messrs. Stuart Low and Co., Enfield, contributed handsomely of *Cattleya gigas* and the beautiful *C. Gaskelliana Fairy Queen* among others, two very distinct and beautiful forms of *Cattleya Sybil*, *C. aurea* and *C. iridescens*, coming from Messrs. Hassall and Co., Southgate.

FRUIT AND VEGETABLES.

Probably the best and most comprehensive collection of vegetables ever staged was that sent from Aldenham House, Elstree, by

The Hon. Vicary Gibbs (Mr. E. Beckett, gardener), and which, by reason of its excellence, received both the gold medal and the Lindley medal, the highest honours the Council can bestow. Comprising 102

dishes in ninety varieties, it was replete of the best, Edwin Beckett and Quite Content Peas being arranged pillar fashion and showing to advantage. Cucumbers, Scarlet-podded Beans, Table Dainty Marrows, Egg Plant, Capsicum, Tomatoes (red and yellow), Celery, silver Seakale, Beet, Carrots, Onions, and much else being shown. Excellent in quality and perfectly staged, the group commanded attention and received high praise from all.

A dozen bunches of Black Hamburgh Grapes of grand size and superb finish came from

Hon. Major Astor, Cliveden, Taplow, Bucks (gardener, Mr. W. Camm). Grand dishes, too, of Laxton's Latest and Waterloo Strawberries were also shown, both demonstrating the highest cultivation.

Messrs. W. Paul and Son, Waltham Cross, showed orchard-grown fruit-trees, Pears, Apples, Plums, Figs, Cherries, and other fruits being seen in considerable variety. A collection of Cherries (fruiting branches) came from

Mr. Charles W. Muir, Penn, Bucks, Elton Heart, May Duke, Black Heart, and Black Elton being noted. New Zealand Apples constituted a big exhibit, four leading growers contributing thereto. The fruits were unnamed.

Messrs. Sutton and Sons, Reading, showed a collection of culinary Peas, Alderman, Lord Kitchener, Duke of Albany (selected), V.C., and Up-to-date being remarked. Dishes of such half-century-old varieties as Yorkshire Hero and Champion of England were also on view.

A complete list of the plants certificated and list of medals will be found in our advertisement columns.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM JULY 19TH.—*Acantholimon glumaccum*, *Potentilla* (in variety), *Sedums* (in variety), *Ethionema coridifolium*, *E. grandiflorum*, *Androsace lanuginosa*, *Gypsophila*, *Oosma albo-roseum*, *O. tauricum*, *Dianthus* (in variety), *Sempervivums* (in variety), *Lithospermum intermedium*, *Banfia petraea*, *Corydalis pallida*, *C. lutea*, *Genista humifusa*, *Convolvulus Cneorua*, *C. mauritanicus*, *C. althaeoides*, *Gnotheras*, *Tunica Saxifraga*, *Mimulus* (in variety), *Erinus*, *Erodium corsicum*, *Astrichinum Asarina*, *A. glutinosum*, *Platycodon Marieti*, *Lotus Tetragnolobus*, *Linarias* (in variety), *Aubrietias*, *Anthemis*, *Veronicas* (in variety), *Primula capitata*, *P. Bulleyana*, *Campanulas* (in great variety), *Abronia umbellata*, *Lysimachias*, *Hypericums* (in variety), *Scabiosas*, *Salvias*, *Lavateras* (various), *Ostrowskia magnifica*, *Cypripedium spectabile*, *Thalictrums*, *Heucheras* (in great variety), *Viola gracilis*, *V. Rothomagcasis*, *V. bosniaca*, *V. lutea*, *Supuarias*, *Thymus* (in variety), *Glossocoma clematidea*, *Gnaphalium trinerve*, *Valerians*, *Geums*, *Mertensias*, *Bergamots*, *Liliums* (in variety), *Delphiniums* (in variety), *Herbaceous Phloxes* (in variety), *Anchusa Opal*, *A. italica Dropmore var.*, *Pentstemons* (in great variety), *Carnations*, *Erigerons*, *Eryagiums*, *Achilleas* (various), *Verbascums*, *Eupatoriums*, *Chrysanthemum maximum vars.*, *Chrysogonum virginianum*, *Morina longifolia*, *Galegas*, *Romneya Coulteri*, *Tritomas*, *Lupins*, *Linums*, *Lobelias*, *Anthericum Liliago* (St. Bernard's Lily), *Cimicifuga racemosa*, *Dictamnus Frarinella*, *Centaureas*, *Acanthuses*, *Gladioli*, *Sweet Williams*, *Canterbury Bells*, *Stocks* (in variety), *Antirrhinums* (in many colours), *Cosmos*, *Sweet Sultan*, *Mignonette*, *Phacelias*, *Poppies* (in variety), *Forgloves* (various), *Honeysuckles* (in variety), *Sweet Peas*, *Petunias*, *Ageratum*, *Heliotrope*, *Begonias*, *Calceolarias* (various), *Gazania splendens*, *Tufted Pansies* (in many varieties), *Candytuft* (in variety), *Verbena venosa*, *Godetias*, *Clarkias*, *Pelargoniums* (in variety), *Leptosiphons*, *Iris* (in variety), *Senecio japonica*, *S. Clivorum*,

Viburnum Henryi, *V. Carlesi*, *Cistus* (in variety), *Spiræas* (herbaceous and shrubby, in many varieties), *Teucrium fruticans*, *Daphniphyllum macropodum*, *Carpenteria californica*, *Grevillea rosmarinifolia*, *G. sulphurea*, *Nandina domestica*, *Olearia nummulariifolia*, *Escallonia*, *Hardy Fuchsias* (in variety), *Colutea arborescens*, *Weigelas* (in variety), *Philadelphus* (in variety), *Roses* (many species and varieties), *Clematis* (many varieties), *Solanum crispum*, *Nymphaeas* (in variety), *Butomus umbellatus*, *Hemerocallis* (in variety), *Cyperus longus*.

THE WEEK'S WORK.—Pinks, having passed out of bloom, all flower-stalks have been removed and cuttings taken. The cuttings are pulled off the old plants, and, after trimming off the lower leaves, inserted in boxes of sandy soil and placed in a cold frame, which is kept close for a week or two, lightly spraying them overhead two or three times daily. Clematises, Roses, and other climbing plants are making very rapid growth, and a good deal of training is necessary, at the same time removing all weak and superfluous growths. The seed-vessels have been removed from such as *Rhododendrons*, *Laburnums*, etc., to encourage the production of new growth. Sweet Peas have been looked over and all seed-pods removed. As the plants are making much growth, a few of the side shoots were thinned out. The shoots of *Alstromerias* have been thinned, removing all weak and superfluous ones, and placing twiggy sticks amongst the plants for support. *Gladioli* and *Hyacinthus candicans* are sending up their spikes, and these have been supported with neat stakes. Tulips which were lifted from the beds to make room for the summer occupants, and heeled in to ripen, are now well matured, and have been sorted and stored in dry cupboards until the planting season comes round. Cuttings of the following were put in during the week:—*Fabiana imbricata*, *Hypericum elatum*, *Piptanthus nepalensis*, *Genista pilosa*, *Mazus rugosus*, *Dwarf Campanulas* (in variety), *Anchusa myosotidiflora*, *Alyssum spinosum roseum*, *Saponaria Boissieri*, *Gentiana angustifolia*, *Geranium lancastricense*.

F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Strawberries.—The crop of early and main-crop sorts has been an abundant one, but the flavour has not been all that could be wished owing to lack of sunshine. Beds which have to stand for another season and from which runners are not required should be forthwith divested of their oldest leaves and runners, and with the mulch cleared away. This should be followed by a good hoeing, when the surface will then be in good order for the reception of a dressing of manure, which should be spread between the rows directly an opportunity offers. Other beds should be similarly treated so soon as the requisite number of runners has been layered and ready for severance from the parent plant. Where much forcing has to be done a certain number of layered runners should be planted apart from those which will be expected to fruit, to supply runners alone next season. More vigorous and earlier runners are by this method secured, while the delay arising in the clearing of the beds after gathering is over is avoided. When calculating the number of plants that will be required for the making of new beds allowance should be made for giving some of the newer introductions a trial, if that has not already been done.

Protecting fruit.—Nets which have been in use over Strawberry beds have been requisitioned for the protection of Raspberries and Red Currants. To save time when gathering, these are stretched over a rough framework at such a height that it is unnecessary to move them, ingress and egress being had at one corner. Loganberries, to which birds are very partial, must also be netted, and so soon as the dessert varieties of Cherries are cleared of fruit the nets now in use on them will come in for covering Morello Cherries and wall-trained Plums, particularly the early varieties. Gooseberries which are required for dessert have to be securely netted, otherwise blackbirds and thrushes will quickly devour

the fruit. These are best protected in a similar manner to Raspberries. If merely laid on the bushes the nets become torn and damaged to such a serious extent as to be of no further service.

Camellias.—The flower-buds being set, the plants are now the better for being moved outdoors for the next month or so to undergo a thorough rest. A semi-shady position suits them best. Watering must be strictly attended to.

Salvias.—Where planted out, stopping and watering must have every attention, otherwise the plants will be leggy and possessed of but few branches and the foliage fail to retain its colour. Pot-grown plants should not be placed in a too fully-exposed position, otherwise the wood is apt to become too highly ripened, and never flowers so well as when it is in a more succulent condition. Red-spider has also to be reckoned with under the before-mentioned conditions, and is difficult to eradicate once it obtains a good hold on the leaves. A good preventive is weak soot-water, which should be syringed on to the under side of the leaves just about sundown.

Gloxinias.—These will soon be looking their best, and that the flowers may last as long as possible in good condition, a not too moist atmosphere should be maintained and the house well ventilated in the day. Watering needs to be carefully done—in fact, water should be applied only when after tapping the side of the pots the latter emit a clear ringing sound. Some of the best may be marked for propagation by means of the leaves, but, as from a packet of seed saved from a good strain plants can be raised which produce flowers of the highest quality and of the most beautiful colours, it is hardly worth troubling about.

A. W.

MIDLAND COUNTIES.

Peach-trees.—Ripening crops require a warm and fairly dry atmosphere. During dull weather and on cold nights a gentle heat in the water-pipes, with top and bottom ventilation, is necessary to create a circulation of air, otherwise but little fire-heat is used. The trees are looked over daily for the purpose of gathering ripe fruits. This is preferable to placing nets under the trees, as the fruits are apt to be bruised by coming into contact with the net. Any leaves which obstruct the light are tied back so that the Peaches are exposed to the sun. In later houses where the fruit is swelling, attend to the watering of the borders as often as necessary, as neglect at this stage may seriously affect the crop. The surface of the borders is not always a reliable guide to the state of the roots, as frequent syringings tend to make the surface-soil wet. The surface should be pricked up occasionally with a fork, taking care not to injure the roots. Trees carrying good crops of fruit will derive much benefit from a mulch of well-decayed manure.

Summer pruning.—It is not possible this season to give as much time as usual to hardy fruit-trees, but summer pruning must be completed as soon as possible, so that the foliage on spurs and at the bases of shoots on Pear-trees may be exposed to sun and air to assist it to ripen perfectly by the end of the season.

Raspberries, Black and Red Currants are a very heavy crop, and much time is occupied in gathering fruit for preserving. As soon as all the Raspberries are gathered the old canes will be removed and the young growths tied to the trellis to prevent injury from wind, thinning out the weakly ones where they are too crowded. The recent rains have been most acceptable here, but sunshine is needed now for all fruit crops.

Pears are looking remarkably well. The rains have not only caused the fruits to swell, but have also cleansed the trees from insect pests. Trees that are bearing heavy crops have been thinned of superfluous fruits. This increases the size of those that remain and conserves the energies of the trees, so that they will be in a condition to bear again next year.

Amarylises (Hippeastrums) are now ripening up their growth in a cool, airy house. The soil in the pots is kept slightly moist so long

as the foliage continues green. During bright weather a shading of light tiffany is afforded to protect the foliage from the fierce rays of the sun. When more advanced in the ripening process they will be exposed to the full sun.

Cinerarias pricked off into boxes some weeks ago are now ready for potting up singly into 3-inch or 4-inch pots, according to the size of the plant. After potting, they will be placed on a bed of ashes in a cold-frame, having a northern aspect, keeping the atmosphere moist and shading the plants whenever the sun is powerful.

Violets for frames have been mulched with horse-manure from which most of the straw was shaken. All runners are kept cut off, the plants well watered in dry weather and occasionally syringed with clear soot-water as a preventive of red-spider.

Celery.—The Celery-fly has made its appearance, and constant hand-picking and frequent applications of soot are necessary to keep it in check.

Brussels Sprouts.—Strong, established plants from the first sowing have been earthed up and the soil made firm about them to prevent the wind blowing them about.

Globe Artichokes.—As soon as the Artichokes are cut the old stems will be removed and a good watering given. They will then be expected to provide supplies later in the season.

Carrots.—The latest sowing of Carrot Early Gem will be made on a south border at the end of the month. Earlier sowings have been thinned to 3 inches apart and a sprinkling of soot applied during showery weather.

Winter Greens.—The season has been a very favourable one for the transplanting of Brassicas, and failures are likely to be fewer than usual. Wood-pigeons have done a considerable amount of damage to the plants in these gardens. All vacancies that have occurred, in consequence, have been filled up, and in some cases it has been necessary to place nets over the plants. These green crops may still be planted on the various plots of ground as they become vacant, and although the plants to be used now will be the small ones that were left from the first planting, they will have made nice, sturdy specimens since the bed was thinned. If they fail to make such large plants as the earlier ones they may turn in at an opportune time when such vegetables are becoming scarce.

Potatoes.—Many of the early varieties will now have completed their growth and are ready for lifting. This must be attended to before the tubers have time to start a second growth, which will soon take place, especially after a heavy rain when the ground is warm. It then becomes a difficult matter to secure sufficient tubers for next season's planting. Potatoes intended for seed should be exposed to the sun for a few days before they are stored, a shed where the air can pass freely through being the best place to keep them until frosts set in, when they must be removed to a place of safety. The ground from which this crop is lifted will be utilised for other crops, such as Spinach, Turnips, Lettuce, and Endive. Sowings of

Lettuce are now made weekly in order to secure an unbroken supply. At this season I prefer to sow the seeds thinly, allowing the plants to mature in the same position rather than transplant the seedlings. In this way the plants will afford a succession of heads and grow better during the next few weeks, especially if the weather is dry.

F. W. GALLOP.

SCOTLAND.

Hardy Plant Borders.—*Lilium candidum* appreciates a mulch or some liquid manure. This fine Lily is, in these gardens, rather capricious, and occasionally refuses to flower for a season. When this happens the spikes during the ensuing year may be depended upon to be better than the average. Roses now require some attention. Suckers must be promptly removed, and if it is not possible to mulch the beds the surface can be kept hoed. As has been previously indicated, as little

tying as possible has been done among the dwarfer hardy plants. There have been several occasions upon which torrential rains have fallen, but these plants have not been very noticeably knocked about. Taller plants, of course, are being staked and tied as occasion requires.

Hedges.—The time is at hand when the annual summer trimming of hedges has to be attended to. In the case of Beech hedges of some size the work is done with the hedge-knife. The common Yew makes a close and good hedge, and so does Holly, but the former must be kept away from boundaries, or from places where cattle or horses can reach it, owing to its poisonous nature.

Vegetable garden.—The present season will, unless an improvement takes place, be noteworthy, not only for its excessive wet throughout June and the early part of July, but for the very heavy nature of these rains. The soil in these gardens is rather stiff, so that after an exceptionally wet day it is not advisable to tread upon it for a day or two. Nevertheless, in the early part of the week some progress was made. The bulk of the Leeks was planted, the variety used being the old Musselburgh. In planting, a 4-inch drill is cut out with the hoe. In these drills, which are 14 inches apart, holes about 10 inches deep are made with a crowbar, and into these the young plants are dropped. No soil is given at planting time. The roots soon take hold, and as growth progresses the drills are closed in. The Leeks obtained by this method are of quite a usable size and thickness, more so, I think, than those grown in trenches, while they are certainly hardier in the event of a severe winter. All available corners are being gradually filled with various kinds of winter vegetables—Curly Kale, Savoys, and Sprouts—while a good batch of Celery has been planted out on the level for flavouring. There is usually a demand for Celery for seasoning, and by putting in such a batch the plants in the trenches are not interfered with. Peas and Climbing French Beans were staked, the latter after being thinned. Weeds have been very much more troublesome than usual, for not only has there not been the time in which to attend to them, but the weather has been unfavourable for their destruction. A spell of bright, sunny weather would therefore be welcomed.

Plant-houses.—Double Petunias do not now seem to be so popular as was at one time the case. Their blooms are not suitable for cutting, but, nevertheless, the plants have a certain value for house work in vases, and last fairly well. Somewhat straggling in habit, they require to be staked neatly and as unobtrusively as possible. *Diplacus glutinosus* is also grown to a certain extent. It is another plant which is not now very generally met with, and its rather sticky nature (as in the case of the foliage of Petunias) rather detracts from its value. Still, it is very free flowering and lasting, and gives variety to a mixed collection of plants in a greenhouse. Zonal Pelargoniums and double Begonias, among other things, continue to be bright, and wall-grown plants of the former, and of Heliotrope, flower freely during the late summer and autumn. Watering, owing to the prevalence of dull and sunless weather, has been less exacting than is usual just at the present time. A practice is made of inspecting the plants every morning, for there is always something which dries up more rapidly than others. In the stove, the earlier lot of *Pancreatum fragrans* is throwing up spikes. The blooms of these are very showy and sweetly perfumed, but unless they are shaded their beauty is rather fleeting. *Eucharis Lilies* could, I daresay, be had in bloom practically throughout the year if plenty of plants were available and the correct treatment given. These fine bulbous plants, being of an evergreen nature, should not be dried off, but removed to a cooler house and given sufficient moisture to keep the foliage in a robust and healthy condition. After about a month of this treatment they may be returned to the stove, and, to carry them on, an occasional allowance of weak manure-water or of well-diluted scot-water can with advantage be given. Syringing is necessary to maintain these and other stove plants in good health

and free from insects—that is, except during their period of flowering.

Calceolarias can now be sown. The seeds are very minute, and care in sowing is necessary. Let the pans be made ready, levelled, and sprinkled with fine sand before the packet is opened. Sow very thinly and evenly, and press the seeds lightly into the soil. No covering with sand or soil is needed, and until germination takes place let the pans be covered with obscured glass and regularly inspected and watered as becomes necessary. As soon as the seedlings are fit to handle they should be pricked off into boxes or pans. Do not reject the smallest seedlings, for observation has shown that such sometimes develop into the best plants and carry the showiest heads of bloom.

Hardy fruit.—Netting has been done in the case of late varieties of Strawberries. These all over, owing to the lack of sun, will not mature at their usual date, and while Raspberries, too, were netted in the course of the week they will not be ripe for some little time. Altogether, in the case of fruit, it has now become quite evident that the season will be a late one. Wall fruit continues to make progress, if slowly. At this time the regulation of young wood has generally been begun, but the weather conditions are delaying such work. It is hoped, however, to make a beginning in the course of the ensuing week.

Cabbages for spring.—Small sowings of these were made during the early part of the week. Dwarf sorts, such as *Ellam's*, April, Flower of Spring, and Harbinger are preferred; but much more reliance is placed on plants from sowings at a later date. The seeds are sown in drills for convenience in cleaning, and the seedlings, when ready, are pricked off into nursery beds for a time. The sorts mentioned above, being all of small size, may be planted out closely, and if the ground is in good heart no manuring at present is necessary. To have stout, robust, young plants which will stand over the winter let the soil be made as firm as possible before planting.

W. MCGUFFOG.

Balmæ Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Rose Yellow Banksian not flowering (*Miss McDouall*).—This Rose, as a rule, flowers on the wood of the previous year. These growths should never be pruned, but allowed to grow naturally, the only artificial aid afforded being to spread them out somewhat, so that the sun and air may reach them, and so assist in ripening the wood. If there exists a lot of shoots, and they are at all crowded, these should be cut out, taking care to preserve the long wiry growths of the present year. Your best plan will be to try and dispose of the Lavender flowers in your own district.

Diseased Hollyhocks (*W. W.*).—Yes, the plants are very badly affected with the Hollyhock disease (*Puccinia malvacearum*). There is no reliable remedy for it, therefore the best plan is to pull up and burn the affected plants at once. Those that do not seem to be attacked should, as a precaution, be washed with soapy water, in which a liberal proportion of flowers of sulphur has been dissolved. The sulphur will settle at the bottom of the vessel, and must be frequently stirred up when the water is being used. Sulphur is very effective in destroying almost any fungus, and may this one in its very earliest stage, but it will not do so when established.

Myrtle not blooming (*G. G.*).—Possibly though the plant is healthy and the shoots quite green, the plant may be too weak to flower, caused partly by its being pot-bound. We should advise you to have it repotted, using a compost of three parts good fibrous loam to one part each of leaf-mould, well-decayed cow-manure, and sand. Be very careful as to watering until you find that the plant is growing freely. As regards your Fuchsias, you made the mistake of not waiting until they started into growth before you repotted them. Had you done this the roots, if watering was carefully attended to, would have soon taken hold of the fresh soil.

FRUIT.

Raspberries failing (*Mrs. E. C. Daniell*).—The reason of the malformation of the fruits is, we think, due to the flowers, after they opened, having been injured by cold winds or frosts or a combination of the two. We have carefully examined the specimens you send, and have failed to find the slightest evidence of any insect troubles. The canes, too, are very weak and thin, showing plainly that the roots require feeding. Even the young canes you send are very poor. Your best plan will be to give the plantation a heavy mulch of manure, and, if the weather is dry, water freely. We have found fish guano a good stimulant for Raspberries. This should be thinly strewn on the surface at intervals throughout the season and washed in. Have you been digging the ground in which the Raspberries are growing? If so, this would account in great measure for the failure, as doing so destroys the surface-roots, which are indispensable to the well-being of the plants. The fruiting canes should be cut out as soon as the crop has been gathered, so as to strengthen the canes for the next year's crop.

VEGETABLES.

Cucumber plants failing (*J. Cheeseborough*).—It is just as we suspected. The stems of your plants are affected with causer, caused either through growing in an unsuitable soil or too much moisture near the affected parts. In your case the cause, if we may judge from the specimen of soil attached to the roots, is the soil, which is much too light and rich. The woodlice are not the cause of the trouble, but at the same time you ought to take steps to clear them out by pouring boiling water over them if you can find out where they congregate. You will find an article dealing fully with Cucumber culture in our issue of June 19, 1915 (p. 379), a copy of which can be had of the publisher post free for 1½d.

MISCELLANEOUS.

House slops as manure (*E. J. H.*).—This should have four times its proportion of water added to render it fit for use as liquid-manure. Before using it it is as well to expose it in a large tub to the atmosphere for a few days, adding the water when it is to be used. It is greatly helped if either a peck of soot or a couple of pounds of guano or other artificial manure put into a bag be soaked in the manure. There are really no growing crops that may not be benefited by it. If the artificial manure be added, then let the added water be as six to one of the other. The exposure softens the liquid. Great quantities of such valuable plant food are wasted, which if put into a large tub in an out-of-the-way place in the garden would prove most valuable manure. We do not reply to queries by post.

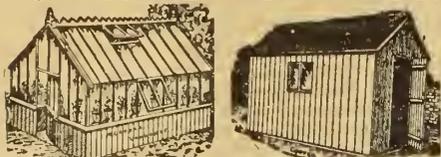

SHORT REPLIES.

W. M. Crowfoot.—Your Carrots have been attacked by the grub of the Carrot-fly. See reply to "Anglian," in issue of July 22nd, page 356. Kindly send some further particulars as to your Celery and Onions. The trouble is evidently in the soil, and it would be well to get the advice of a practical gardener who could see the plants.—*James Kirk*.—See reply to "Ayton," in our issue of July 22, page 365, re "Calceolarias failing."

Write to-day for copies and Catalogue, with illustrations and full specification.—**GEORGE BEATSON, "LION CYCLE" WORKS, 83, MOSELEY STREET, BIRMINGHAM.**

NOTICE TO ADVERTISERS.

As we have to print a large edition of **GARDENING ILLUSTRATED**, it is essential that advertisement copy should reach us not later than the Friday morning for the issue of the week following.

We commence printing on Friday, and no advertisement can be altered or stopped after first post on Friday morning.

GARDENING ILLUSTRATED is obtainable on the Wednesday preceding the date shown on the paper.

63, LINCOLN'S INN FIELDS, LONDON, W.C.

Awarded Gold Medal, Anglo-American Exhibition. Commended by the Royal Horticultural Society.

WEED KILLER

For Destroying Weeds and Moss on Carriage Drives, &c. Used in R.H.S. Gardens, Kew, &c., &c.

"ACME" LAWN SAND.

Marvelous destructive effect on Weeds and Moss on Lawns. Fertilizes the Grass; no other manure needed. 7 lbs., 1/9; postage 7d.; 56 lbs., 10/-; 1 cwt., 19/-; Carriage Paid.

Other Garden Chemicals, prices and particulars on application.

THE APPLE AND ITS FUTURE.

THE Apple, the noblest fruit of the North, deserves our best care, but our growers are confused with too many kinds in fat catalogues and exhibitions, in which fifty kinds may be shown out of season, that no good progress is made with the very best kinds for general use. Americans and Colonials are not so mistaken as we are. They send us vast quantities of their best kinds. As fine might be grown in the warmer parts of Great Britain and Ireland. Some of our Apples are as good as any grown in the northern world, with the gain of freshness. The energy that should carry us through is dissipated by growing too many kinds. What might be done by a Society, if we had a good one, would be the encouragement of the growth in orchards of one of each of the best kinds of Apple, such as, say, Blenheim, Ribston, and Sturmer.

Growers should be encouraged to make an orchard of one such standard kind, of which we cannot well have too many. When we grow a first-rate kind in quantity all that concerns it is better attended to—culture, cleanliness, gathering, and so on. A great point would be to promote the natural form of the tree, far too much attention being now paid to dwarfing stocks and ways of pruning. Over-pruning and bad pruning are far too common, reducing the amount of fruit and doing infinite harm in other ways. A rigid choice of kinds should be made. Diseases are far too rampant, American blight perhaps worst of all. With our present knowledge of washes we should be able to control these. In this way our own growers might compete with those of any country, but never so long as we cultivate a great number of poor kinds instead of those of finest quality. Now our Horticultural Society promotes a delusion by encouraging the exhibition of many kinds often out of their true season of use. We can never compete with the Pacific coast and other growers without a complete change of system, and such as Keswick or Mank's Codlin, Ribston, Blenheim, Sturmer, Roundway Magnum Bonum, Bramley, Alfriston, Wellingington, and Lane's Prince Albert, grown well, orchard fashion, would be worth more than ten times the number we now have.

Some control of the issue of new kinds might well be in action. Of recent years new Apples have been sent out which are no improvement on old kinds (some quite inferior). This evil might be

lessened if we have a revision of a standard fruit list every three years, as is done by the Pomological Society of France, with power to exclude from it any worthless new kinds arising from time to time. Controlled in that way the trade would be more cautious about bringing out new kinds before they were well tried.

NOTES OF THE WEEK.

Gentiana Przewalskii.—This Gentian, of prostrate habit and rich purple flowers, keeps well in the house. Some buds brought to town kept for over a week, and buds gradually opened in water. It may vary from seed. The form I have is as good in colour as *G. verna*.—W.

Rose Effective.—A Rose no garden should be without is Effective. It is a good doer in a poor soil; colour crimson, which does not die off magenta, sweet scented, good in the bud and in the open flower; long stalks for cutting; strong, healthy foliage; excellent for pillar or wall.—TOCKENHAM, WILTS.

Snapdragons of the day.—These are now very fine in colour and often distinct. Such a gain in a hardy plant is notable, all the more so as in some soils certain flowers, like Stocks and Asters, give a poor result. They are now very fine at Peekham Rye Park, planted in groups of one colour. Sweet Williams in the same place are fine, especially the self-coloured ones. Both races are full of interest for flower-gardeners.

Arum Lilies in ponds.—In the gardens at Great Ballards, New Milton, near the New Forest, an old gravel pit has been utilised for water-loving plants, and here the Arums do very well in water from 1 foot to 3 feet in depth. They are left undisturbed through the winter, and do not appear to suffer from the frosts. At Pylewell Park, Lymington, Arum Lilies are planted in the Grass at the edge of a large pond, and do remarkably well. They are also planted in the water itself, but I think the clumps at the edge of the pond have the better effect.—BOURNE VALE.

From Ashbourne.—Would it not be advisable for your correspondents to note down any combination of pleasing colours which arises in their gardens, often the result of chance, but useful to others if noted? For example, the Anchusas, both Dropmore variety and Opal, when grouped are apt to produce an effect too overpowering in blue, but when combined with the

larger forms of Daisies the mixture of white and blue is good and light. Both these plants flower at about the same period in July. Escallonia langleyensis looks well in a mass, but a better effect can be produced if some of the softer rose-coloured forms of the Wichuraiana Roses are allowed to ramble through and over the Escallonias.—RICH. H. BEAMISH.

Antirrhinum gibraltarium.—A very graceful plant I had not seen before: colour, a bright rosy-purple. It seems hardy on my rock border. This genus seems to have more interest for us than it used to have, though we have long enjoyed the Snapdragon, now so rich in colours. At Kew it is thought to be a narrow-leaved form (*angustifolium*) of the common Snapdragon.—W.

Moss Roses.—All of these, especially the white sorts, are well worth growing. The white kinds are less frequently met with than the pink varieties, but if not quite so showy, they are equally charming. Among them may be mentioned Reine Blanche, easily recognised by its foliage, which at times approaches to a golden-green—if a colour may be so described. Somewhat similar, but quite distinct upon comparison, is Comtesse de Murinais. Other good white Moss Roses may be found in Blanche Moreau and White Bath. It seems a pity that these old-time favourites have been almost eclipsed by the introduction of the popular Hybrid Tea Roses.—KIRK.

Rock Roses in Wales.—Will your correspondent "D." tell me where Cistus Loreti is to be had? I am surprised to read that *C. cyprius* is less hardy than some other kinds. The winter of 1894-95 did no harm to plants at that time about four years old. Two of these now cover a space of 9 yards and are about 8 feet high. I always cut them back in August and September, and again in March. There is not more than 1 foot of soil above the solid rock where they grow. The true *C. purpureus* was planted here in 1895. It was given me by the late Rev. W. Kingsley, of South Kilvington, Yorkshire, who grew this and other species in a glass-house. *C. purpureus* and *lusitanicus* are more particular than any others here as to the position where they grow. A south-west aspect is best. Though the *Cistus* family always does well here, I never before saw them in such perfection as during the present season, and the flowers never before lasted so long. *C. purpureus* opened its first flowers on June 5th, and there is

still plenty more to come (July 23rd). A very beautiful variety of *C. algarvensis* was discovered by Mr. Bowles last autumn at Woodbridge. I think it is the most beautiful I ever saw.—E. CHARLES BUXTON, *Coed Derw, Bethus-y-Coed.*

Nomocharis, a new Chinese Lily.—A new genus, intermediate between *Lilium* and *Fritillaria*, is among the most recent additions to garden plants from China. A plant of it in flower was shown recently at a meeting of the Royal Horticultural Society by Professor Bayley Balfour, who has been most successful in the raising and growing of new introductions from China. Two species of *Nomocharis* have been described, namely, *N. meleagrina*, found on the Mekong in Szechuen by Soulie, and *N. pardanthina*, found by Delavay on Mount Koulapo in Yunnan. *Nomocharis* differs botanically from both *Lilium* and *Fritillaria* in the following characters:—The inner segments of the corolla are much wider than the outer, the lower part of the filaments is inflated and hollow, and the foveole are multiplied and partly free.—*Field.*

Verbascum leianthum.—This is, perhaps, the noblest herbaceous plant that I have ever seen. I came across it some four or five years ago at Christchurch, in the nurseries of Mr. Maurice Prichard, from whom I subsequently obtained a plant. He assured me that it had never seeded successfully with him, but contrary to this is the experience of myself and of the Rev. C. O. S. Hatton, who procured a plant at the same time. We both have a number of seedlings, and mine, which are now in flower, form an imposing group of some twelve specimens. Although at Christchurch I saw some plants 15 feet high, in this dry climate of the eastern counties 12 feet seems to be the maximum attained. The stem, 7 feet in height, is surmounted by fifteen racemes of soft, yellow flowers, inclined at a slight angle to the main central spike, which is vertical. The stigma is pale green, and the five anthers of similar tint but very floccose. The size of the leaves is relative to that of the plant, the largest one I can find being 15 inches long and $7\frac{1}{2}$ inches in its broadest part. Their colour is a greyish-green, and they are smooth on the upper surface but woolly underneath. The sight of the spiral columns against a background of evergreens is one never to be forgotten.—G. H. RAYNOR, *Hazeleigh Rectory, Essex.*

Hardy white Jasmines.—It is not generally recognised that there are two quite distinct hardy Jasmines with white flowers. To my mind the better is the common Jasmine (*Jasminum officinale*), which forms such a charming feature on many a country cottage. The second form has, before now, been assigned specific rank under the name of *Jasminum affine*, but it is by Mr. Bean regarded as but a variety of the common kind, from which it differs in being of stronger growth, while the individual flowers are larger, and with a purplish tinge on the exterior, more pronounced in the bud state than when fully expanded. The young leaves and growing points of the shoots are also tinged with red, a feature which is wanting in the common kind. The perfume of *affine* is also, I think, less pleasing than that of the other. Probably from its more vigorous growth *affine* appears to be grown now to a greater extent than *officinale* itself. At all events, it may be far more generally met with than was the case a few years ago. Anyone in need of a white-flowered, fragrant Jasmine should plant the old and well-proved *Jasminum officinale*.—K. R. W.

TREES AND SHRUBS.

HYBRID TREES AND SHRUBS.

It is remarkable that so few hardy trees and shrubs should be hybrids. Except in a few genera, very little systematic hybridisation appears to have been carried on, some of the most valuable hybrids owing their origin to chance rather than to the efforts of the gardener. Probably the most energetic hybridist among shrubs was the late M. Lemoine, of Nancy. With the two families—*Philadelphus* and *Deutzia* alone—his labours will always be remembered by the numerous showy hybrids which appeared in the course of the last twenty-five years. In other directions he has also done good work, for numerous *Diervillas*, *Syringas*, and autumn-flowering *Ceanothuses* originated in his nursery. The names of Jackman, Cripps, Smith, and Moser are household words where Clematises are concerned, for they have given us many of the fine varieties belonging to the *Jackmani*, *lanuginosa*, *patens*, and *florida* groups. *Rhododendrons* and *Azaleas* have for many years been favourites with the hybridist, but comparatively few species have been used as parents when the large number available is taken into consideration. Names such as Gill, Mangles, Godman, Loder, and Davies are intimately connected with hybrids raised between semi-tender species, whilst amongst hardier sorts some of the more important workers have been Messrs. Waterer, Paul, and Davies. Deciduous *Rhododendrons* or *Azaleas* were originally raised in Ghent, but many of the finest hybrids were raised later by the late Mr. A. Waterer and Mr. Cripps. In the genus *Rhododendron* alone there is still plenty of work to be done, more particularly among the dwarf species, and if suitable mates could be found for such species as *racemosum* and *lepidotum*, new races of garden *Rhododendrons* would doubtless appear. The advisability of keeping strict records of all crosses, with the time of seed collection, sowing, appearance of plants, and time of flowering, is very important, for in the event of a particularly useful or interesting plant being raised, the hybridist is asked to supply all kinds of information about it. With this in view every cross should be recorded in a book kept for the purpose, and other items of information added at the proper time.

Professor Henry, of Dublin University, has interested himself in hybrid forest trees during late years, and in addition to clearing up the origin of certain trees which, in the past, have been regarded as doubtful species, by proving them to be hybrids, has raised several new trees, some of which show surprising vigour.

In the following notes attention is directed to some of the more important hybrids at present obtainable.

DEUTZIA.—The various hybrid *Deutzias* have been raised by crossing the following species:—*D. gracilis*, *D. parviflora*, *D. discolor*, *D. discolor purpurascens*, *D. setchuenensis*, and the hybrid *D. Lemoinei*. One of the earliest hybrids was *D. Lemoinei*, which appeared in 1891 from a cross between *D. gracilis* and *D. parviflora*. It is well known by reason of its large corymbs of white flowers, which appear out-doors towards the end of May, although its great value is for forcing. The advent of *D. discolor* and its variety *purpurascens* gave the opportunity to raise kinds with coloured flowers, and the purple, which is a conspicuous feature in the flowers of those two shrubs, more especially the latter, is found in varying degrees in the hybrids. The widely-open

blooms of these kinds have also exerted an influence upon the hybrids, and a considerable difference in the shape of the flower is noticeable. Some fine hybrids between these kinds and *D. gracilis* are found in *floribunda*, *grandiflora*, *rosea*, *campaulata*, *carminea*, *eximia*, and *multiflora*, all very showy. *D. campaulata* and *D. multiflora* have white flowers, whilst those of the others are more or less deeply stained with pink or purple. *D. kalmiæflora* is an exceptionally fine shrub of erect habit, with flat, rounded flowers, whitish within, and rich rose without. Its parents are *D. discolor purpurascens* and *D. parviflora*. Other fine hybrids may be found in *myriantha*, *Avalanche*, *Apple Blossom*, and *Roseball*. The most familiar

MOCK ORANGES (*Philadelphuses*) are *P. Lemoinei* and its variety *erectus*, the latter an improvement on the type, and may be considered one of the best twelve flowering shrubs. Its parents are *P. coronarius* and the dwarf *P. microphyllus*. Other fine hybrid Mock Oranges are *Boule de Neige*, *Gerbe de Neige*, *Boule d'Argent*, *Bouquet Blanc*, *Candelabra*, *Manteau d'Hermine*, *Mont Blanc*, *Mer de Glace*, and *Rosace*. Hybrid

DIERVILLAS include such kinds as *Eva Rathke*, *Lavallei*, *Pascal*, *P. Duchatre*, *Saturne*, *Conquerant*, *Seduction*, and *Abel Carrière*. Garden forms of

LILAC are legion, but perhaps the most distinct hybrid is *Syringa chinensis*, often called the Rouen Lilac. It originated by crossing the common *S. vulgaris* with the dwarf Persian Lilac, *S. persica*. The result is a plant, growing at least 12 feet high, and the same in diameter, of free-flowering character with the elegant inflorescences of the Persian Lilac, though intermediate in size between those of both parents. One would now like to see the Chinese *S. villosa* crossed with the fine garden kinds. Little has been accomplished with the ornamental flowering species of

RIBES. The only hybrid of importance is *R. Gordonianum*, a cross between *R. sanguineum* and *R. aureum*. In habit it most closely resembles *R. sanguineum*, but the flowers are of an intermediate character. A hybrid

FORSYTHIA is found in *F. intermedia*, its parents being *F. suspensa* and *F. viridissima*. It is free flowering and intermediate in character between the parents. There are several hybrid

BROOMS, the best known being *Cytisus præcox*, an early-flowering shrub with cream-coloured flowers. Its parents are *C. albus* and *C. purgans*. Two attractive dwarf hybrids are *C. Beani* and *C. kewensis*. Both were raised at Kew from naturally fertilised flowers of *C. Ardoini*. *C. Beani* bears golden blossoms and *C. kewensis* cream-coloured flowers. Another Kew hybrid is *C. Dallimorei*, a hybrid between *C. scoparius Andreanus* and *C. albus*, the former the female parent, which was isolated whilst in flower. Growing as tall as the common Broom, it differs from any other kind in having rosy-purple flowers.

BERBERIS STENOPHYLLA is the most conspicuous hybrid *Barberry*. An excellent evergreen, it is also a first-rate flowering shrub. Its parents are *B. Darwini* and *B. empetrifolia*.

HYPERICUM MOSERIANUM, a very useful summer and autumn-flowering shrub, is a hybrid between *H. calycinum* and *H. patulum*. The genus does not, however, appear to be an easy one to raise hybrids from.

MAGNOLIAS have been enriched by numerous hybrids raised between the white-flowered *M. conspicua* and the reddish-purple *M. obovata*. Notable kinds

are *Soulangeana*, *Lennei*, *rustica*, and *Norberti*.

PYRUS SCHEIDECKERI is a very free-flowering semi-double-flowered Crab, a hybrid between *P. prunifolia* and *P. floribunda*. Another free-flowering hybrid is *P. Kaido*, which is considered to be the result of a cross between *P. spectabilis* and *P. Ringo*. *P. auricularis* is a curious hybrid between *P. Aria* and *P. communis*, its red and yellow, Pear-shaped fruits being borne in large, flattened heads. Among

LABURNUMS are several hybrids between *L. alpinum* and *L. vulgare*, of which *L. Watereri* and *L. Parksi* are good examples. The graft-hybrid, *L. Adami*, is interesting on account of its producing three distinct kinds of flowers on the same tree—ordinary racemes of yellow *Laburnum* flowers, racemes of purple flowers, and flowers and growths such as are natural to *Cytisus purpureus*. The union of *C. purpureus* and *L. vulgare*, by grafting,

cærulea). From its exceptional vigour and rapid growth the wood is superior to any other kind for the manufacture of bats. The tree is recognised by its stiff, erect habit, female flowers, and bluish leaves. Another useful hybrid tree is the London Plane (*Platanus acerifolia*), whilst there are several useful Elms and Oaks. One of the most interesting of the Oaks is *Quercus Lucombeana*, a hybrid between the evergreen Cork Oak (*Quercus suber*) and the deciduous Turkey Oak (*Q. Cerris*). D.

BERBERIS ARISTATA.

THIS is a valuable late-flowering kind welcome after so many of the family have passed out of bloom, and, with others, shows the variety of beauty among the Barberries, both evergreen and summer-leaving. All who care for hardy shrubs should plant a small group in the coming autumn. It is a Himalayan species of vigorous habit, and forms one of the

this year, so I cannot tell if they are the male or female tree. I enclose a piece.—ETHEL CASE.

[We should certainly put the trees out of harm's way. Fatal accidents have occurred where trees, as in your case, seemed to do no harm.—Eb.]

New plants from China.—The third expedition into China to discover new plants suitable for introduction into the United States has been completed by Mr. Meyer, plant collector, who recently returned to Washington after a three-year trip in the Far East. As a result of this expedition through China, of the specimens secured were the jubebe, a fruit new to this country and which may be suitable for use in the south-west, a wild Peach resistant to alkali, cold, and drought, certain Chinese Persimmons larger than any hitherto known in this country, a number of aquatic food roots and vegetables for the utilisation of swamp land, some thirty varieties of vegetable and timber Bamboos, and a number of Chinese vegetables, bush and climbing

Flowering sprays of *Berberis aristata*. Hillbrook Place, July.

produced this remarkable hybrid. Another instance of hybrids raised by graft influence is seen in the two or three kinds of *Cratægo-Mespilus*. In this case the trees bear three different kinds of leaves, flowers, and fruits from the result of grafting a Medlar upon a Thorn. The red-flowered

HORSE CHESTNUT (*Æsculus carnea*) is another good example of a showy-flowered tree, whilst other hybrid Chestnuts are found in *Æ. Lyoni*, *Æ. neglecta*, and *Æ. plantierensis*. Amongst the several hybrid

SPIRÆAS, *S. arguta* is one of the best, and few shrubs command more attention during early April, for its white flowers are borne in such profusion as to almost hide the branches. Among

CISTUS and **HELIANTHEMUM** are several attractive hybrids. Among large-growing trees are several hybrids which are superior for commercial purposes to the parents. The most notable one is

THE CRICKET-BAT WILLOW (*Salix*

largest specimens in the family. Well-grown examples may be anything up to 16 feet or 18 feet high, with a diameter of quite as much. Although a deciduous plant, it retains its leaves until well on into late autumn, and it is unusual for all the leaves to fall before the second or third week in December. The leaves are of good size, dark green, and sparsely armed along the margins with sharp spines. The pale yellow flowers, produced in racemes each 2 inches to 3 inches long, in June, are succeeded by oval, purplish fruits, which ripen in September, and are covered by a thick glaucous bloom, which gives them a curious appearance, for the purple is here and there visible through the glaucous coating. It is easily propagated from seeds, grows rapidly, and quickly forms large specimens.

The Yew.—The Yew-trees which are growing by the side of the road opposite this house are constantly nibbled at by the horses, goats, and cows with no bad effect. They did not bloom

Roses, shrubs and trees, and a Hickory-tree, the first found in China. Elsewhere English Walnuts were discovered in a wild state, and the discovery of the wild Peach is regarded as significant because it seems to prove that the Peach may have been a native of China rather than of Persia. The discoveries of native and hardy Oranges and other Citrus fruits, a number of which have been brought to this country for breeding, give added evidence that China was the home of the Orange, which was introduced into other countries probably by early Portuguese travellers. Of interest also are the collections of aquatic food plants secured in the recent expeditions. These include Water Chestnuts, Water Nuts, and a number of aquatic bulbs, as well as the Water Bamboo. The Chinese, the explorer found, have mastered through centuries of experiments the process of using swamp lands for the raising of food crops.—*Gardeners' Chronicle of America*.

FRUIT.

FRUIT-BOTTLING FOR SMALL-HOLDERS.

AMONG the industries to which the small-holder should direct his attention fruit-bottling is worthy of wider consideration than it at present receives. This method of preserving fruit is quite distinct from jam-making, and is more simply carried out. It enables the grower to make the utmost use of all fruit which reaches maturity, for in a year of abundant crops all surplus fruit, and in any year fruit which cannot be sold at a fair price or consumed, can be preserved for future home requirements or for sale during the months when fresh fruit is unobtainable. Bottled fruit, properly preserved, is a wholesome and valuable food, which finds a ready and profitable sale. There are probably two reasons why fruit-bottling is not yet so common as it deserves to be:—

(1) The process is considered to be difficult, and (2) there is a general impression that a special and costly sterilising apparatus is absolutely necessary. With regard to the first point it is only necessary to say that few tasks could be more simple or easy to perform than fruit-bottling, which requires only the care and attention of an ordinarily intelligent person. As to the second point, a patent steriliser is not necessary where only small lots of fruit are to be bottled, a large saucepan, boiler, fish-kettle, or similar vessel for heating water alone being requisite. When, however, the small-holder finds that he can profitably dispose of a fairly considerable quantity of bottled fruit, a larger type of boiler holding one or two dozen bottles, or a small sterilising outfit, may usefully be employed. A few shillings will purchase a suitable flat-bottomed iron pot to hold several bottles, while a small steriliser holding about a dozen bottles for use with an oil or gas stove or a kitchen fire may cost £1 5s. to £3 3s. If it be desired to preserve several hundred bottles of fruit in one season it may be worth while to invest in a steam steriliser holding three or four dozen bottles, or even more.

THE OBJECT OF STERILISING OR "PRESERVING."—When it is desired to keep fruit until the fresh article is not available, some means is necessary which will arrest the ordinary processes of decay or "rotting" induced by a variety of low forms of life—bacteria, yeasts, fungi, and possibly even minute larvæ of insects. The most convenient plan is to employ heat to destroy such agents of decay as are present, and prevent the subsequent access of others to the fruit by enclosing it in hermetically-sealed or perfectly air-tight vessels. This accomplished, practically in one operation, fruit will remain sound and good for a considerable period, even several years. The desired result is usually attained by placing the fruit in glass bottles having air-tight caps, subjecting the whole for a certain time to a given temperature by means of water or steam, and closing the bottles while still surrounded by steam.

BOTTLES.—Wide-mouthed bottles specially made for the purpose may be obtained through almost any ironmonger at from 3s. to 6s. 6d. per dozen complete, the price varying with the size and quality of the bottles. Many persons have a decided preference for bottles with glass tops instead of metal tops, and some like the "screw" tops; whilst others prefer the bottles whose tops, covers, or discs are held in position by "spring" clips. When counting the cost of the process of bottling it is well to remember that the same

bottles, when once obtained, may be used repeatedly until broken; the chief renewals required are rubber rings, which are used with bottles for rendering them air-tight. It is absolutely essential that the bottles should be air-tight. An imperfectly-fitting rubber ring or cover may be sufficient to cause failure after perfect sterilisation; the rings and covers must, therefore, fit perfectly. As this cannot always be guaranteed, there will be an occasional bottle which will not be successful. This should be used at once, or the contents may be emptied into a new bottle and re-sterilised.

THE BOILER OR STERILISER.—As stated above, in the case of small lots an ordinary saucepan, boiler, or fish-kettle may be employed to hold the bottles. While such a vessel is over the fire the bottles should be raised somewhat above the bottom of the vessel, or some of them may crack; this may be arranged by placing in the vessel a false wire bottom or a board $\frac{3}{4}$ inch thick and standing the bottles on this. The bottles should then be "shoulder-deep" in the water. The temperature should be slowly raised to the desired point, and the caps should be fastened tightly before the vessel is removed from the fire. For fruit-bottling on a somewhat larger scale a boiler or steriliser may be constructed to hold a dozen or fourteen bottles. Different types of these have been placed on the market. Where large quantities of fruit are to be bottled, a steam boiler may usefully be employed in conjunction with a steriliser. This steriliser is a galvanised iron vessel about 4 feet long, 2 feet wide, and 2 feet high, raised somewhat from the ground on four legs. The lid consists of a galvanised iron plate fitting over a number of bolts on the rim of the steriliser and screwed down by means of winged screws; two handles serve to remove it or place it in position; a perforation allows the insertion of a thermometer; and a perforated brass or copper vent in the centre allows the escape of steam. The steam is admitted at the bottom by means of a pipe from the boiler, and is equally distributed round the steriliser by a perforated pipe running round near the bottom. Cold water can also be admitted at the bottom by a tap and pipe connected with the usual water supply. An overflow is provided at one end for the water, and a tap for the purpose of emptying the steriliser at the bottom. Bottles when filled are placed in rows in the steriliser on a perforated galvanised iron sheet or false bottom raised about 4 inches above the bottom of the steriliser on a ledge; they should not be fastened down, but caps should be as nearly as possible in position. The lid is screwed on and the thermometer inserted (the bulb standing in a jar of water inside the steriliser), and steam is then gradually admitted in increasing amount to raise the temperature slowly to the desired point. After maintaining such temperature for the requisite time steam is partly shut off, the lid is removed, and the bottles quickly closed down by means of the gloved hands while the live steam is still playing round the bottles. Steam and cold water are now admitted together, the water being gradually increased and the steam decreased in order to reduce the temperature quite slowly and avoid breakage of bottles. Finally, when the cold water reaches the shoulder of the bottles, these may be removed to finish cooling while another batch is treated. Such a steriliser will hold from six to eight or nine dozen bottles according to their size, and may cost about £20 to £24.

FRUIT SUITABLE FOR PRESERVING.—Any fruit may be preserved by the bottling pro-

cess, either whole or sliced. Apples, Pears, Apricots, Peaches, Limes, Shad-docks, and Lemons may all be used, though the bulk of bottled fruits consists of Plums, Gooseberries, Cherries, Raspberries, Loganberries, and Currants. Plums and Gooseberries are probably most largely used. When once properly sterilised and the bottles quite air-tight the fruit will keep almost indefinitely, Plums, Gooseberries, Raspberries, Blackberries, and Currants bottled in 1903 being quite good in the winter of 1910-11.

THE USE OF SYRUP.—The use of syrup is not essential, pure water being equally as suitable and a little more transparent, and thus improving the appearance of the fruit after sterilisation. Moreover, a thin syrup spoils the natural flavour of the fruit without making it sufficiently sweet to render further sweetening unnecessary when used. Sugar, therefore, should either not be used, or it should be used at the rate of from $\frac{1}{2}$ lb. to 1 lb. (according to the acidity of the fruit) of pure cane sugar to 1 quart of water. Raw beet sugar should not be used, as it renders the syrup "cloudy," but pure cane sugar leaves the syrup tolerably clear.

SELECTING AND PREPARING THE FRUIT.—The degree of ripeness of the fruit has a considerable effect on the appearance of the fruit after the bottling process is completed. Fruit should be slightly under-ripe for bottling, as the skin does not then break so readily during the process of preservation; with ripe fruit, breaking of the skin can hardly fail to occur, and the appearance is apt to be spoiled. In this respect under-ripe fruit will bear a higher temperature without injury than ripe fruit, but in no case need the temperature rise higher than 200 degs. F., and in practically all cases 190 degs. F. is sufficient. All fruit used should be sound and without speck or injury of any kind. It is best gathered dry, but if it be damp or wet it should be heated a little longer. All fruit should be carefully graded, only that of equal size being placed in the same bottle. Good results are not attained by mixing large and small fruits, while such mixtures have not a satisfactory appearance. "Windfall" Apples and Pears may be bottled if damaged portions are rejected. Preparation before bottling varies somewhat according to the fruit concerned—for instance, Gooseberries should be topped and tailed; Currants shredded from their stalks with light fingers; Rhubarb skinned and cut into pieces of a uniform size; Cherries must be stalked, and, if possible, stoned; the hull should be removed from Raspberries; Plums, Greengages, and Damsons must have their stalks removed; large juicy Plums must be cut into halves before being placed in the bottle; Peaches and Nectarines should be skinned, stoned, and halved; Apples and Pears must be peeled and "quartered." A silver or plated knife only should be used for preparing fruit. Great care should be taken in placing the fruit in the bottles, for if these are imperfectly filled some fruits (e.g. Strawberries) after sterilisation will rise, and leave a large space at the bottom without fruit. Many have experienced this in their first attempts at fruit-bottling. A stout stick or piece of wood, about 12 inches in length—blunt at one end and rather pointed at the other—is very useful in arranging and gently pressing fruit into position in regular layers. The fruit should be selected of nearly equal size and then arranged in the bottles systematically, pressing it into place by means of the stick when necessary. The bottles should be filled to the top of the neck, still using a little force in packing if requisite. Soft fruits like Gooseberries

and Currants require shaking together in order to ensure close packing; Rhubarb should be placed as far as possible in upright rows; Plums should be arranged in rows, as by this means more fruit can be placed in the bottles. As the bottles are filled with fruit, water may be added to within $\frac{1}{2}$ inch of the rim, or syrup as described above may be used. In the case of bottles with screw caps, the latter may be placed on loosely and partly screwed down in order that they may be readily screwed down tightly directly the sterilising process is completed. In the case of bottles with caps (either glass or metal) and springs the rubber rings should be softened in hot water, the cap should be

the bottles then securely fastened down; in the case of screw caps the tops should be screwed further if possible as the bottled fruit cools. Each lot of bottled fruit should be examined two or three times during the first day or two, and if any doubt is entertained as to the condition of any of it the doubtful bottles should be re-sterilised at once. This may sometimes be necessary owing to faulty caps.

TEMPERATURES FOR STERILISING.—The temperatures at which fruits are bottled will in part depend on the period for which such temperatures are to be maintained. One authority states that the temperature should be maintained for fifteen or twenty minutes at about 165 degs. F. in the case

such organisms are rendered incapable of further development, except in occasional instances, which do not necessarily arise from any defect in the process. For Peas, Beans, and other vegetables sterilisation should be complete; to effect this higher temperatures are necessary, for not only do these vegetables contain abundant nitrogenous matter, but they are deficient of organic acids.—*Leaflet No. 250 Board of Agriculture and Fisheries.*

PLANTS AND FLOWERS.

ORCHIDS.

ORCHIS MACULATA.

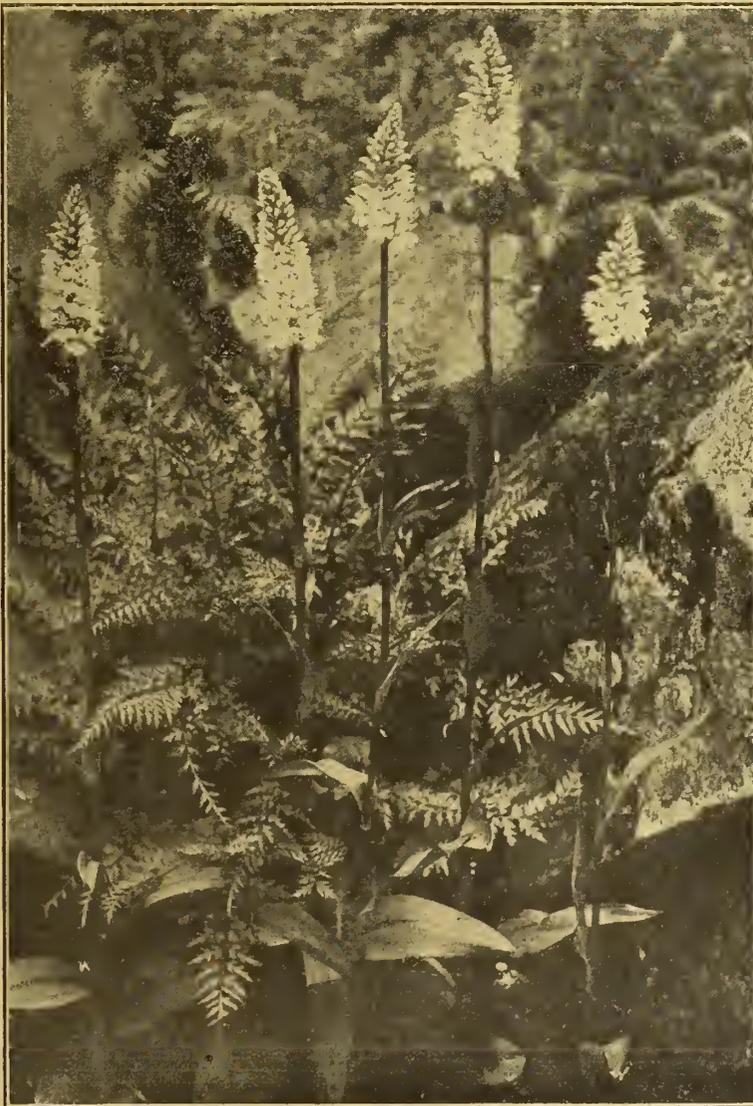

This has much to recommend it, the tall, handsome spikes of variously coloured flowers lasting for a long time when brought into the house. The foliage, too, is pretty, so beautifully spotted and blotched that it always arrests attention, even when the plants are not in flower. Few native plants are more easily grown, for if lifted carefully in the autumn and planted at once in good, rich loam, it will very soon become established. There are pure white forms of the spotted Orchid, but, as a rule, they are not so vigorous as the type. The group of the white form we figure to-day is growing in Sir Frank Crisp's rock garden at Friar Park.

ODONTOGLOSSUMS.

WHEREVER cool Orchids are grown, the Odonoglossums, especially those of the crispum type, form the bulk. For the most part, hybrids are less difficult to grow than species, but all prove amenable to ordinary cultivation.

The flowering period extends nearly the year round, so a few plants will require repotting at intervals, and the majority will need attention in February and August or September. Ordinary flower-pots are chosen, and filled to one-third of their depth with drainage. The compost consists of Osmunda-fibre, peat, and Sphagnum Moss in equal parts, and if the plants are not thriving as they should do, a moderate sprinkling of partly-decayed Oak or Beech leaves may be added. The whole is cut up fairly fine, and thoroughly mixed a week before it is needed. Small plants that have filled their pots with roots may be moved on without much disturbance, but from examples that have lost their roots all the old soil must be picked out, the dead roots cut away, and a few of the back pseudo-bulbs removed, two or three behind each growing point being ample. Such plants generally need a smaller pot, and a little more drainage may be added with advantage. All those that have been repotted may be arranged together where they are not so likely to get overdone with water. Keep the surroundings moist, and shade from all strong sunshine. An average temperature of 50 degs. to 55 degs. should be maintained during the winter, but in summer 10 degs. higher will do no harm.

To be successful with cool-growing Orchids due attention must be paid to ventilation. It is a common mistake with amateurs to open all the ventilators to their fullest extent, which allows a large quantity of dry air to enter and dry up the moisture. If the outside atmosphere is fairly moist, only one set of ventilators should be opened at a time, and they must be on the leeward side of the house. When the weather is hot both may be left open an inch or two throughout the night. A moist atmosphere is necessary, and this is brought about by sprinkling water on the stages and floors twice or thrice daily, allowing it to become fairly dry for a

Orchis maculata alba. Friar Park.

placed on, and the spring placed in position ready for fastening down directly sterilisation is completed.

STERILISING.—When the bottles of fruit are ready they should be placed in the boiler or steriliser and the temperature raised quite slowly, perhaps at a rate of 2 degs. F. per minute, otherwise bottles may crack and the skin of the fruit may break and the appearance of the produce be spoiled. The temperature necessary will vary with the kind and ripeness of the fruit, but a lower temperature than 165 degs. F. is quite unreliable, and a higher temperature than 190 degs. F. or 200 degs. F. is unnecessary. The necessary temperature should be maintained for a time suitable for the fruit being sterilised, and

of small fruits such as Gooseberries, Currants, Cherries, and Raspberries, and at any temperature between 165 degs. F. and 190 degs. F. in the case of Plums, Apricots, Peaches, and Pears. For sterilising the latter fruits forty minutes at a temperature of about 165 degs. F. to 170 degs. F. will answer.

Though the word "sterilise" is employed in this leaflet it is not to be understood that the process of fruit-bottling involves complete sterilisation, for some organisms may not be destroyed by heating to the temperatures suggested. Owing, however, to the absence of oxygen, the relatively high percentage of organic acids present, and the small amount of soluble nitrogenous matter in the fruit juices,

couple of hours at mid-day. Shade will be needed whenever the sun is bright. The best blinds are undoubtedly the wood lath roller kind, which can also be employed during the winter as a protection from frosts. *Odontoglossums* that are well rooted enjoy a copious supply of water during their growing period, but when the pseudo-bulbs are fully developed a less quantity will suffice, although the plants must not be dried off like many other Orchids. If the pseudo-bulbs are kept plump no harm will accrue. SABOX.

Vanda cœrulea.—On account of the colour of the flowers this *Vanda* always commands attention. The colour varies from light blue to a darker tint, the size of the individual flowers also varying. In some collections a house or division is set apart for its accommodation, but this is not essential, as the plants will succeed equally as well if placed in the *Cattleya* division. During their period of growth the warmest end should be chosen, their immediate surroundings kept moist, and the roots liberally supplied with water. Any repotting should be done when root-action begins, but, as a general rule, they will go several seasons if top-dressed annually with clean, fresh *Sphagnum* Moss. The plants may be grown either in pots or Teak-wood baskets, which must be filled to one-half of their depth with drainage, the compost consisting of *Sphagnum* Moss, with a moderate quantity of *Osmunda* fibre. A good time to repot is when new roots are formed. Plants that have lost their lower leaves may have a portion of the old stem removed, so that the leaves are near the surface of the soil. Newly-potted plants must be carefully watered until root-action is evident. When the plants are at rest remove them to the cool end of the house, discontinue damping down, and only give sufficient water to maintain the leaves in a plump and rigid condition.—B.

Cypripedium insigne.—This, decidedly an amateur's Orchid, is occasionally recommended as a window plant, but one could hardly expect good results from such treatment, while it is frequently referred to as a cool-house Orchid. Tolerably good specimens can be grown in such a structure, but the finest plants are produced when a few degrees more warmth are given. Frequent disturbance of the roots must be avoided, but there comes a time when the plants begin to deteriorate unless they are given fresh rooting material. This consists for the most part of good fibrous loam, but if this is heavy a little peat and partly-decayed Oak-leaves may be added, together with a sprinkling of sand and crushed crocks. A few weeks after the flowers are cut any repotting may be carried out, filling the pots to one-third of their depth with drainage. The soil is made fairly firm and brought up to within $\frac{1}{2}$ inch of the rim. After repotting, very careful watering is needed, but when root action is evident the supply must be increased. Plants not repotted must be given water liberally. Shade from strong sunlight and spray the plants overhead during hot, dry weather.—B.

Weed killer (W. B. Smith).—Get 1 lb. of white arsenic, 1 lb. sulphate of copper, and 1 pint common muriatic acid or spirits of salt. Water to 5 gallons. Boil until dissolved, and decant the clear liquor. Mix 1 gallon with 25 gallons of water and apply with an ordinary rose pot in sufficient quantity to go to the roots of the weeds. It is best applied when the ground is damp but not wet. We think, however, you would find it safer and better in every way to purchase the weed killer ready for use, using it according to the directions sent therewith.

GARDEN FOOD.

MEATLESS DISHES.

The *Sheffield Telegraph* has been offering prizes for meatless dishes, and with good results, in the district where such things have not been much thought of before. People went to see, in doubt, and came away, we hear, much impressed.

The following are a few of the recipes to which prizes have been awarded:—

SAGO AND RHUBARB.—3 oz. of sago or tapioca, $\frac{3}{4}$ lb. of rhubarb, 1 pint of water, and 3 oz. of sugar; a little Lemon-juice. Soak the sago all night. Slice Rhubarb, lay it with the sago in the dish, and cook until clear. Add sugar and Lemon-juice, and cook again for a few minutes. Serve with cream or custard.

SAVOURY EGGS AND SALAD.—Two hard-boiled eggs, 2 oz. breadcrumbs, pepper and salt, 2 oz. ground Nuts, one-quarter teaspoonful marmite, one tablespoonful water or stock; a little cheese grated or other flavouring. Method: Mix Nuts, breadcrumbs, and seasonings. Dissolve marmite in a little stock or water. Make all into firm mixture. Divide into two, flatten each piece on a floured board, roll the mixture round, working out all cracks. Coat with egg or a thin batter of flour, salt, and milk. Roll in crumbs and fry in smoking hot fat for four or five minutes. Drain carefully. When cold cut in two and arrange on salad.

FRUIT JELLY.—1 lb. Rhubarb, one Orange, sugar to taste, water, $1\frac{1}{2}$ oz. cornflour. Method: Stew Rhubarb with sugar and a little water carefully without breaking. Lift out of syrup and put aside to cool. Make syrup up to one pint with water, add thin rind and juice of Orange, and simmer for a few minutes. Strain on to blended cornflour, return to pan, and cook for five or six minutes. Pour into wet mould and when set turn out on to glass dish, and arrange Rhubarb round. Any other fruit may be used. Syrup left from tinned fruit is excellent.

EGG AND CHEESE FRITERS.—Two hard-boiled eggs, 2 ozs. of dried cheese, cayenne, salt, 2 ozs. of short pastry, pieces left over from any dish will do. Boil the eggs twenty minutes, cut into rings. Roll out the pastry, then cut rounds with pastry cutter, put one ring of egg, a little grated cheese, seasoned with salt and cayenne, wet the edges, make into small turnovers. Dip in egg and breadcrumbs. Fry in boiling fat a golden brown. These make a nice dish for lunch, or a savoury for dinner. Garnish with Parsley; serve hot.

LENTIL ROAST.—1 lb. Lentils, 2 lb. chopped Onions, $\frac{3}{4}$ lb. breadcrumbs, $\frac{1}{2}$ lb. cold mashed Potatoes, pepper, salt, Parsley, or seasoning to taste. Method: Wash Lentils, cook gently in an earthenware jar in oven with Onion, or in a porridge pan for about an hour, when soft add other ingredients. Shake, place in a greased dripping tin, and bake till brown. Serve hot with brown gravy and Apple sauce.

POTATO BOATS.—Take four Potatoes and four poached eggs and a little sauce. Roast the Potatoes; when done, cut one side off each, and take out the inside. Mix with a little cream and butter. Return same to the Potatoes with a little of the sauce. Fry the eggs; cut with oval cutter, put in the Potatoes, and serve. Sauce.—Half-gill of white sauce, 1 teaspoonful of Lemon juice, one yolk of egg, $\frac{1}{2}$ oz. of butter, pepper and salt. Boil all together for a few minutes.

MACARONI AND EGGS.—4 oz. of macaroni, 2 eggs, 1 oz. of butter, 1 oz. of flour, sugar, salt, and pepper. Break the macaroni in short lengths, put it in rapidly boiling water, salted, and cook until tender. Melt the butter in a stewpan, add the flour, and cook for a few minutes. Then break the eggs into the pan, letting them set a bit before stirring. Then season with a little Tomato ketchup, a pinch of sugar, and salt to taste; let it boil for a few minutes, then add the macaroni, and when thoroughly hot turn on to a dish and serve.

MACARONI SAVOURY.—Ingredients: 1 lb. Tomatoes, 2 oz. breadcrumbs, $\frac{3}{4}$ lb. macaroni, $\frac{1}{2}$ lb. cheese, 1 pint white sauce, two tablespoonfuls vinegar, seasoning. Cook the macaroni in fast boiling water for about twenty minutes till tender, adding a teaspoonful of salt to the water, then drain and allow to cool, cut into

inch lengths, skin Tomatoes, and grate cheese. Then grease the pie-dish with a little butter, put a layer of crumbs at the bottom of the dish, then a layer each of Tomatoes, macaroni, and cheese alternately till the dish is full. Make an ordinary white sauce, adding the vinegar, stir the vinegar into the sauce very quickly to prevent curdling, pour the sauce over the dish, and put into a moderate oven for half an hour till it is a nice brown. This dish looks more appetising if eaten cold turned out into a silver dish, sprinkle the top with a little Parmesan cheese and decorate with Parsley and short sticks of macaroni in the centre of the dish.

NUT CUTLETS.—6 oz. shelled Walnuts, two breakfastsups breadcrumbs, one tablespoonful flour, $\frac{1}{4}$ pint milk, $\frac{1}{2}$ oz. butter one teaspoonful Onion juice, mustard spoonful of made mustard, salt and pepper to taste; an egg can be added if desired. Crumble the breadcrumbs, put Nuts through the mincing machine. Make a stiff white sauce with flour, butter, and milk, add seasoning, then the Nuts and crumbs. Mix well together and put aside to cool. When cold form into cutlets, egg and crumb them, and fry in deep fat. Serve with either Mushroom, Tomato, or bread sauce.

MARGUERITE PUDDING.—4 oz. flour, 2 oz. butter, 2 oz. sugar, one egg, two tablespoonfuls milk, half teaspoonful baking powder, two tablespoonfuls Strawberry jam. Mix the flour and baking powder thoroughly. Cream the sugar and butter together. Beat the egg and add to milk, then beat gradually into butter and sugar, lastly adding flour. Beat well; put the jam at the bottom of a small pudding-bowl which has been well greased. Fill up with the pudding mixture, cover with greased paper, steam one and a half hours.

TOMATOES AU GRATIN.—Butter a flat baking dish and put in Tomatoes cut in halves. Sprinkle over them some breadcrumbs, grated cheese, chopped Onion, and Parsley. Place them in an oven, and when ready to serve squeeze a Lemon over the whole, add salt and pepper.

VEGETABLE SAUSAGES.—Ingredients: Three Carrots, three Onions, one Turnip, one Parsnip, $\frac{1}{2}$ pint split Peas, one tablespoonful chopped Parsley, two eggs, 2 oz. butter, pinch Sage, $\frac{1}{2}$ lb. breadcrumbs, salt and pepper. Method: Soak Peas overnight and boil until perfectly soft, boil all vegetables together, and when tender pulp with the Peas to a smooth paste. Add the eggs beaten and breadcrumbs, Sage and Parsley; when thoroughly mixed roll into sausages; dip each into flour, beaten egg, and breadcrumbs. Fry in butter a golden brown. Serve hot garnished with Parsley.

VEGETARIAN CUTLETS.—One teacupful of Almonds, one teacupful of Brazil Nuts, one teacupful of breadcrumbs, one teaspoonful mixed herbs, one teaspoonful Onion juice, one tablespoonful of white sauce to bind the ingredients together, pepper and salt to taste. Method: Blanch the Almonds, and put them through a mincer with Nuts and breadcrumbs; add the other things, then form into cutlets; dip in egg and breadcrumbs; fry ten minutes in boiling fat. Stick a piece of macaroni in the end to form a bone, and to hold the frill; serve round a mashed Potato shape.

LENTIL AND NUT CUTLETS.—Two small Tomatoes, 2 oz. Lentils, 2 oz. breadcrumbs, 2 oz. ground Walnuts, one small Onion, two small Apples, pepper and salt to taste. Method: Cook Lentils, Tomatoes, Onions, and Apples together; when cold add breadcrumbs and Nuts with pepper and salt, and make into a firm mass, then form into cutlets, dip in egg and breadcrumbs, and fry a nice brown.

BARLEY SOUP.— $\frac{3}{4}$ oz. butter (or margarine), one dessertspoonful of prepared Barley blended together. Add 1 pint white vegetable stock, or milk, flavour with pepper and salt, boil together for fifteen minutes.

RHUBARB JELLY.—1 lb. fresh Rhubarb, about $\frac{1}{2}$ lb. sugar. Wipe Rhubarb, cut in pieces, put into a saucepan with sugar and enough water to cover the stalks. Stew till soft (five to ten minutes), strain through a cloth, and make up to $1\frac{1}{2}$ pints, with water if required. Take 2 $\frac{1}{2}$ oz. cornflour (prepared), mix to a smooth cream with a little juice, bring the rest of the juice to a boil. Take saucepan from fire, pour mixed cornflour slowly in, stirring vigorously. Bring to boil again and boil for three minutes. Pour into mould and cool.

OUTDOOR PLANTS.

TREE AND SHRUB GROWTH ON THE WELSH COAST.

LIKE Cornwall, the South of Ireland, and the West of Scotland, the coast of Wales—particularly Anglesey and Carnarvonshire—enjoys a mild and moist climate, and so it is that numerous half-hardy trees, shrubs, and plants that could not be wintered out-of-doors under ordinary climatic conditions, find there a congenial home. One has only to visit such places as Penrhyn Castle, in Carnarvonshire, or Bodorgan and Penrhos, in Anglesey, to find out what a wealth of trees and plants can be successfully cultivated in the mild, ozone-laden atmosphere of these pleasantest of Welsh places.

At Penrhyn Castle, *Fuchsia Riccartoni*

Castle to the model village of Llandegai. At Glynegarth and Rhianfa, on the Menai Straits, there are also collections of rare and beautiful plants, including the too-little-seen *Eucryphia*, *Fabiana imbricata*, the best forms of *Cornus*, and hosts of alpine and herbaceous plants that will not succeed far away from the coast. *Pinus insignis*, a by no means hardy tree, appears in all its beauty, and produces excellent timber along the coast near Holyhead, while at Penrhos, where *Libonia penrhosiensis* was raised many years ago, the selection of rare and desirable flowering plants and shrubs is always an attraction to visitors to that part of Wales. Penrhos was one of the first places where the *Leptospermum* was successfully grown in the open air. The *Lapageria* is often quite vigorous in gardens near the coast.

A. D. WEBSTER.

to the sides of the pot suggested that a hard surface was preferred by them, and by subsequent experiment I decided this was so. The chief thing, however, is to get a perennial continuity of growth, and, this ensured, a good flowering is almost sure to follow. To this end occasional division and replanting are necessary. A fair amount of moisture is essential; too much shade favours leaf-growth at the expense of flowering. In dry, hot soils or in heavier soils that contract with heat and drought the plant does not extend sufficiently, and flowers are few and far between. In the autumn of 1915 I set out a considerable number of young established plants with a view, ultimately, to forming a big colony, wedging in near the surface occasional bits of stone over which the rhizomes could travel. The plants have flowered surprisingly well, the fine

Penrhos.

and *Hydrangea hortensis* flourish amazingly, the former in particular attaining a great height and vigour. Less hardy trees and shrubs have stood unharmed for fully half a century, including the beautiful *Cunninghamia sinensis*, *Chamarops Fortunei*, *Eugenia Ugni*, several of the *Escallonias*, the *Myrtles*, *American Allspice*, and some Australian shrubs. The flower garden and grounds at Penrhyn contain one of the choicest collections of rare shrubs and other flowering plants that is to be found anywhere in the country. Amongst conifers that succeed well at Penrhyn Castle, special mention may be made of the *Corsican Pine*, which towers yards in height above any other trees in the woods where it has been planted. The *Douglas Fir* also does well, there being some giant specimens by the drives leading from the

OURISIA COCCINEA.

This Chilean plant has been referred to recently in *GARDENING ILLUSTRATED* as "the despair of many gardeners," and there is no doubt that some experience trouble, not so much in growing as in flowering it. It is, perhaps, insufficiently recognised that it is the extending sections of the rhizomes only that flower, though these may be either the main or the lateral portions, the back or old portions of the rhizomes rarely blooming at all. I got my first lesson of its peculiarities in this respect many years ago from a large pot-grown, frame-cultivated specimen in which the extending rhizomes had got over the pot's rim and were descending the sides. All such bloomed profusely, while the back, *i.e.*, the older rhizomes, were void of flowers. The way the rhizomes adhered

growth they are making full of promise for another year. They are in a bed of rich soil—loam, leaf-mould, and well-decayed manure—and while sheltered from mid-day sun by a near-by *Acer* of some size, get a little afternoon shade as well. The position is a little slope. At Wisley the plant has flowered exceedingly well this year, the growth being also of exceptional vigour. Some years ago, when visiting the late Mr. Kingsmill at Harrow, he stopped in front of a fairly big clump of the *Ourisia*, with the remark, "Tell me what to do with that. I have never yet been able to flower it." "And you never will," I rejoined, "till you lift and divide it, and get the rhizomes nearer the surface." In that particular instance the rhizomes were buried several inches deep. What I suggested should be done is detailed above. In after years that good

gardener was not only never tired of telling me of his success with one of the most brilliant subjects any garden could contain, but he had done what all good gardeners do, passed the hint on to his many friends.
E. H. JENKINS.

THE INFORMAL ARRANGEMENT OF ANNUALS.

It often happens that the effects produced by the association of different kinds of annuals have happier results when practically unconsidered than when formal arrangements have been made either in the planting or sowing, and this is more than usually apparent in a season like the present, when one has to make as bright a display as possible at a minimum of labour and expense. An instance of this is in evidence in a groundwork of *Linaria reticulata*, a rather light maroon flower which, given good soil and a deep tith, lasts a long time, interspersed with small clumps of *Gypsophila elegans* and *Mignonette*. This *Gypsophila*, also the form known as *White Pearl*, are very pleasing companions for *Nemesia Blue Gem*, whilst *G. Rosy Gem* shows to advantage on a white ground; indeed, all the annual forms of what are known familiarly as chalk plants are of light, graceful habit, and either on a large or small scale are most appreciated when rising above a dwarf floral carpet. The many annual yellow flowers also show to great advantage in such informal arrangements, alike as to varying heights and the many different shades in *Calendulas*, *Nasturtiums*, and *Marigolds*, and all rank well in the matter of endurance if decaying flowers and seed-pods are occasionally removed. Among the showy annuals with very brilliant colours *Clarkias* and *Godetias* are prominent, and as many new varieties of each have been raised within the last few years, comprising a great number of different shades, a certain portion of ground can be reserved for them, as neither family associates particularly well with other things.
E. B. S.

Hardwick.

RAISING RANUNCULI FROM SEED.

In your interesting article on growing *Ranunculi* the writer makes no mention of the seed, which I am saving, and should like to know how and when to sow it?—CHARLES PHELIPS.

[In the old days when the *Ranunculus* was a foremost florist's flower, growers saved seed from the very best varieties, and in this way new forms were produced, as we see in the case of *Begonias*, *Cinerarias*, etc., in the present day. The old plan was to gather the seed and keep the seed-vessels intact until the time for sowing came round. Sowing the seed was done in October and February. When it was intended to sow, the seed was separated from the pericarp by scraping it with a penknife, for, like that of the *Anemone*, it is of a woolly and fluffy character. The best compost in which to sow is a light sandy loam, with the addition of some fine leaf-soil. So careful were the old raisers that the compost should be free from insects, that they either exposed it to the action of severe frost or they baked it in an oven in order that no trace of insect life should remain. The seed was sown in boxes or pots, coarse siftings being placed at the bottom for drainage, and then fine soil was filled in. The surface was made quite level and pressed down gently, then the seeds were carefully sown and placed an eighth of an inch or so apart, and then sprinkled with a fine rose watering-pot to cause them to lie flat; then some fine dry mould was employed as a covering, but a very thin one,

it being a part of the practice to cover them as thinly as possible.

The late Dr. Horner, who was a great authority on the *Ranunculus* in his day, recommended that the seeds be sown at the end of March, his reason for doing so being that they germinated more quickly then than at an earlier period of the year. The seed-boxes were placed under a wall when sown late, or in a frame for a time when sown early, and then in the open under a wall, open to all the influences of weather. When the seed is good, the seedlings will appear above the surface in a month or so, and they should during the summer have such supplies of water as they may require. When the foliage dies down the bulbs can be taken up, put away in shallow boxes or drawers for the winter, then if planted out in beds in spring they will flower the following June.]

NOTES AND REPLIES.

Fungus on Christmas Rose leaves.—I enclose a leaf from one of my Christmas Roses, and will feel greatly obliged if you will kindly tell me what has gone wrong with it. The plant flowers well and the leaves come all right at first, but gradually they go, one by one, like the enclosed, until by October there are very few remaining on the plant. They are planted on a border facing north, but others on west and south borders are going in exactly the same way. The soil is light and sandy, the manee garden being about two miles from the sea.—M. MUIR.

[The leaves are badly attacked by the Hellebore leaf-mould fungus (*Ramularia Hellebori*). All that can be done now is to collect and burn all the affected parts of the plants, removing and burning if possible 1 inch or so deep of the soil about the plants, which is probably full of the spores of the fungus. In spring periodical syringing with sulphide of potassium should be started, and if kept up at intervals of two or three weeks for some time this would doubtless keep the fungus at bay. One ounce of the sulphide to two gallons of rain-water will be strong enough, and care should be exercised to wet all parts of the plant, the under as well as the upper surfaces of the leaves. Prior to adding fresh soil to replace that removed, a dusting of air-slaked lime should be given. In all probability the plants will be weakened by the disease and replanting will be necessary.]

Geranium Traversi.—I see "W." refers to this plant as "very dwarf, with rosy flowers," which scarcely answers to its habit as grown here. I got a plant from Bees' in 1913, and there is no reason to doubt its genuineness. It has pretty silky stems and rather less silky palmate leaves, and abundant pink flowers which are rather disappointing. It is hardy enough, but capricious. In 1913 the plant grew luxuriantly; not so big as *G. sanguineum*, but much bigger than *G. cinereum*, and spread almost as much as *G. Wallichianum*. Every flower sets seed, which germinates rapidly, but the seedlings are impatient of removal. In 1914 the plant refused to grow at all the summer, so I rooted it up to make room for a self-sown seedling, which is now coming into bloom on a neat little plant, having survived seven weeks' snow and rain in February and March. Another seedling protected in a frame during the winter has grown rank and rather coarse. I am trying another in very sandy soil. Just now all these plants seem to exude moisture symmetrically in the leaves and on the bud-tips every night, which looks as if they had more moisture than pleases them. This moisture is not dew, as the soil and other plants close by, such as *Geranium*

argenteum (Lissadell's Mallow-coloured), *Erodium corsicum*, and *Pelargonium Endlicherianum* (which survived this winter unprotected), remain quite dry.—L. J. ROGERS, 6, Hollin Lane, Leeds.

Foxgloves.—In a rather shady part of a shrubbery within the garden walls a number of self-sown Foxgloves of the usual colour have been permitted to develop. The other day a visitor commented rather sarcastically upon their presence, remarking that as Foxgloves grow in every ditch, hedgerow, and lane in the neighbourhood, they were surely out of place in the garden. Had the critic been, as I have, in districts where Foxgloves are unknown in their wild state, I venture to think that his opinion as to their value would be revised. Even although, as is the case here, these plants are common, yet they have quite a value in places such as that indicated.—W. McG., *Balmoe*.

The Masterwort (*Astrantia major*).—This is quite a pretty alpine, although not by any means a showy species. It has quaint flowers of a pinkish colour surrounded by whitish-green bracts, which are beautifully netted and veined. It is of the easiest culture, best in sun, but doing quite well in shade, and not at all particular as to soil. It grows from 1 foot to 2 feet high, and is easily increased by division.—W. O.

Violets.—These must now be encouraged to make all the growth possible by frequently hoeing between the plants, watering whenever necessary, adding a stimulant in the shape of liquid-manure or soot-water if progress in the matter of growth is not so satisfactory as could be desired, and in keeping runners suppressed. Syringing in dry weather should have daily attention.—A. W.

LADY GARDENERS.

I THINK your correspondents have missed a point in the discussion in your paper on the employment of women in horticulture, namely, the number of people whose incomes have been seriously curtailed and will be permanently curtailed by the war. Hitherto these people have employed the jobbing gardener. Now, unless the family turn to, the garden must go. Surely it is better for the girl gardener to know how to prune fruit and Rose trees, use the proper washes to keep pests under, and raise vegetables and herbs, than lay the garden down to Grass.

The price of fish and meat is still rising, and more important than ever becomes the proper management of vegetables, poultry, and pigs. Not all the women who enter colleges will become head gardeners—not many of the men who make gardening a profession rise to the top. The foundress of Glynde Nursery says that two years are all too short a period to acquire "the whole art of gardening," and a woman who has a head gardener's post in view would go as an improver and work her way up. But two years in a college should save an intelligent woman from costly blunders and serious mistakes when she comes to take her own garden in hand, particularly where she has never had the opportunity of learning at home in a big garden worked by an experienced staff.

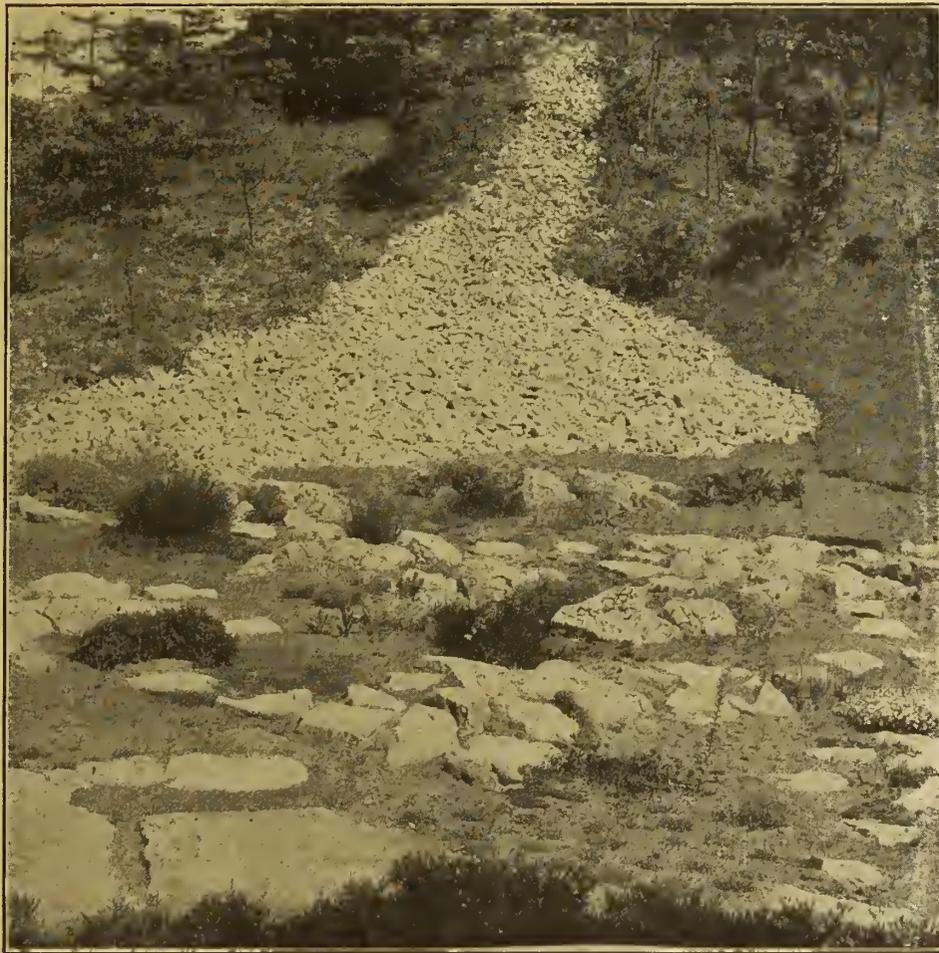

THE SQUIRE'S WIFE.

[Quite right. The young lady should know something about gardening, and now there are various opportunities of learning it. Some things that are mentioned here are very easily learned, such as pruning Roses, though often made a needless fuss about. It is unnecessary for a young lady to go to college to learn some of the essentials of simple gardening. The best way is for her to start doing things in the home garden. Gardening may be as good an exercise as hockey, golf, shooting, and other pastimes which now are practised by young ladies.—Ed.]

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

A MORAINE.

THE moraine is a very good idea. For generations the poor alpine plants have been the victims of over-feeding, but no one took any notice, until recent years, that in their native moraines these plants are very much starved and never benefited by any manure or leaf-mould even. People now begin to see that the true way is to grow them in rough conditions, on chipped stones and gravel. The best example of this we have seen is at Friar Park, of which we give an illustration. The plants there seem quite happy. The stones are not overdone, as they so often are, and the effect is quite good.

The moraine at Friar Park.

NOTES AND REPLIES.

Potentilla rupestris.—This, with its white, Strawberry-like blossoms, looks very pretty growing out of a chink in an open position not too sunny. It is a native of this country, but rare, and is well worth growing in the rock garden. It is of neat habit and gives no trouble provided it is planted in well-drained soil. With me it grows equally well in sandy leaf-mould or in a stony, calcareous mixture with plenty of broken brick—a compost which seems to suit a great many alpins. It flowers in May and June and is easily propagated from seed, which it produces freely.—N. L.

Campanula Hosti.—The Campanulas are most valuable for furnishing the rock garden when the glory of the spring-flowering plants is past, and, to my mind, this species is one of the most valuable for this purpose. It is of strong, bushy growth, like our native Harebell, C.

rotundifolia, but of sturdier habit, and the flowers are larger, of a deep blue colour, and borne in the utmost profusion. I have a large clump of it on a somewhat raised part of the rock garden, and it is a glorious mass of deep colour. It is of the easiest culture in any open position in light soil, and, like most Campanulas, appreciates lime. It spreads quickly and is easily increased by division.—N. L.

Sedum spathulifolium.—This is one of the choicer representatives of its large family, and, like most of its allies, only asks for a dry, sunny spot in sandy or gritty soil to do well. It is of quite prostrate habit and has comparatively large rosettes of flat glaucous leaves which look very pretty, especially in dry weather, when they become tinged with red. It is

one of the first to blossom, and has large, flat heads of yellow flowers of the usual Stonecrop type. Although growing fairly rapidly it is quite free from the fault which many Sedums have of spreading over and strangling its less vigorous neighbours.

Campanula pulloides.—This species seems to be much easier to manage than *C. pulla*, at least I have found it so, though I do not think it is nearly so beautiful. The flowers are of a dark purple, but not quite so pure in colour as those of *C. pulla*, and, moreover, they are large, and to my mind coarser looking. I have tried *C. pulla* under various conditions, but it never survives the winter with me, even when grown in the moraine. *C. pulloides*, however, does quite well in a limy moraine in my London garden, and is now giving a profuse display of its large, drooping, cup-shaped flowers.—W. O.

VEGETABLES.

NOTES AND REPLIES.

New Zealand Spinach.—I would be much obliged if you would advise me as to the best way of growing New Zealand Spinach. Does it require a rich soil, and can I raise it in nursery beds and plant it out later on? At present I have very little room, but would like to have as much as possible for winter use, as we use it a good deal.—R. NOLA FERRALL.

[It is somewhat late to sow, though even now, with good culture, excellent results may be secured, as this variety makes rapid growth in dry weather. This Spinach is quite distinct, having a thick, succulent, very tender leaf. The soil for this crop must be well enriched, as, owing to its quick growth, the roots require much food. For an early supply it is best to sow in boxes or pots in frames and gradually harden off. If this plan is adopted, seed should be sown late in March or early April, planting out a month or six weeks later, according to the weather. Sow very thinly, or thin early, to get a strong plant, and, when planting, care should be taken that the ball of soil is not broken. Plant in rows 3 feet apart, and if the weather is dry, water freely. In the open, seed may be sown in May or June in rich soil, well thinning so as to allow each plant plenty of room. Give plenty of water, with occasional doses of liquid manure, when the plants are bearing freely. This Spinach is useless for late autumn or winter supply, as the first frost destroys it. For the autumn and winter you should sow the Round-leaved or Victoria and the Prickly-leaved or Long Standing, doing this early in August in rows 15 inches to 18 inches apart, and thinning freely in the autumn.]

Sowing Cabbage seed.—About the 28th of the present month is a good time to sow seed of suitable varieties for spring cutting. Varieties specially adapted for this purpose are Harbinger, April, Flower of Spring, Matchless, and Ellam's Early. The first-named turns in earlier than either of the others, and if raised from seed sown about the date mentioned heads will be ready for use, in a normal season, in February. In the meantime, the site where the sowing is to be done should be prepared. That growth may be quick and fly kept from attacking the young plants, a dressing of short, well-rotted manure and some wood-ashes should be applied to the surface and dug in. Thin sowing will result in dwarf, sturdy plants. The drills should be 1 foot apart.

Cucumbers in frames are now in full bearing, and, if not overcropped, will continue to give good results for many weeks to come. Cucumbers require unremitting attention to keep them in good order. They are syringed regularly twice a day, the growths stopped and regulated, removing the oldest leaves and any excess of foliage as often as necessary. Top-dressings of suitable materials are afforded as often as the roots find their way to the surface. A batch of seeds will now be sown to furnish plants for cropping in early winter. The seeds are sown singly in small pots and placed in a temperature of 70 degs. to germinate. These should be ready for planting by the middle of August, by which time a house now occupied by Melons will be available.

Parsley.—A quantity of this herb should be raised at this date wherever an abundant supply is needed during winter and spring. It is altogether unnecessary to sow the seed where the plants are to be grown, as when large enough the seedlings can be pricked out in lines either on narrow borders in front of espalier fruit-trees or any suitable position. So treated, the plants make a sturdier growth and are better able to withstand the rigours of winter.

Scarlet Runners.—These require a small amount of attention in the way of seeing that the young growths do not become entwined and in fastening them to the poles after disentangling any found in this condition. So

much wet weather encourages slugs to attack almost everything of a green or succulent nature, the young stems of Runner Beans included, and lime mixed with a certain amount of cinder ashes must still be strewn round about them and continued until they become firm and tough.

Asparagus beds need hand weeding periodically to keep them free from coarse weeds. The Asparagus growths will be supported with stakes, with string stretched between them. In dry weather thorough soakings of water and stimulants are invaluable, as a great deal of the success obtained next season depends on the assistance the plants receive now.

Early Celery.—The moist weather has suited this crop to a nicety, and good growth has resulted. A little soil may now with advantage be placed round the stems, and to a height of 3 inches to 4 inches, after removing a few of the outer or oldest leaves and any suckers which may have formed at the base.

GARDEN PESTS AND FRIENDS.

WASPS.

WHILE it is doubtless true that wasps do much good by the destruction of other harmful insects, it is equally true that when they are present in large numbers they may be responsible for considerable damage. They often ruin large quantities of fruit, while the chance disturbance of their nests in the harvest field and elsewhere may at any time be answerable for runaway horses and the accidents which follow. It is necessary, therefore, that steps should always be taken to keep their numbers within reasonable bounds. Reports which are reaching the Board from various sources all point to the fact that an unusually large number of queens has been observed this spring, and it is therefore to be expected that wasps will be proportionately abundant and troublesome later in the season.

METHODS OF DESTRUCTION.—Methods for the destruction of wasps and their nests are too well known to need more than brief reference. The capture of queen wasps in the spring is always desirable, and is encouraged in many districts by the offer of a small reward. It may also be of interest to note that the "traps" containing beer and sugar, etc., which are found so effective later against the worker wasps, have also this season accounted for large numbers of queens.

The destruction of queen wasps, however, is not likely to have been carried out sufficiently widely to prevent the production of an abundance of workers in the near future, and it would therefore be well if nests could be marked down as early as possible so that they may be dealt with before they have become "strong." Various means are employed in taking the nests. Some prefer the old-fashioned remedies, such as tar, paraffin, or burning sulphur. In many districts, however, the use of potassium or sodium cyanide has become general, and is, undoubtedly, most effective. These poisons are employed in different ways, according to individual preference and the position of the nest. As a rule, a little is placed inside the entrance to the nest after the wasps have returned in the evening. The hole is then blocked up, and further trouble is seldom experienced, though, to make sure, the nest is sometimes dug out after the adult wasps have been killed. When using cyanide, however, it should never be forgotten for an instant that this substance is one of the most deadly poisons known, a minute dose being fatal. If common sense is exercised there should be no danger, but the carelessness with which it is often treated makes this warning very necessary.—*Journal of the Board of Agriculture.*

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM JULY 26TH.—*Buddleia variabilis*, *Ceanothus* (in variety), *Philadelphus* (late-flowering varieties), *Rhus* (in variety), *Weigelas* (late varieties), *Escallonia*, *Spiraeas* (shrubby and herbaceous) (in variety), *Carpenteria californica*, *Clethra arborea*, *C. alnifolia*, *Berberis Wilsoni*, *Daphniphyllum macropodum*, *Calycanthus floridus*, *Ozothamnus rosmarinifolius*, *Colutea arborecens*, *Andromedas*, *Spanish Broom*, *Robinias*, *Abelia rupestris*, *Cistus* (in variety), *Olearia nummulariaefolia*, *Teucrium fruticans*, *Ononis fruticosa*, *Hydrangeas*, *Nandina domestica*, *Hypericums* (in variety), *Solanum crispum*, *Ericas*, *Menziesias*, *Honeysuckles* (in variety), *Clematis* (in variety), *Polygonum boldschuanicum*, *Roses* (in great variety), *Indigofera Gerardiana*, *Hardy Fuchsias* (in variety), *Veronicas* (shrubby and herbaceous) (in great variety), *Campanulas* (dwarf and tall) (in great variety), *Geums*, *Lavateras*, *Acantholimon glumaceum*, *Androsace lanuginosa*, *Aubrietias*, *Dianthus*, *Gentiana septemfida*, *Linarias* (in variety), *Erinus*, *Sedums* (in variety), *Sempervivums* (in variety), *Onosma tauricum*, *Convolvulus mauritanicus*, *C. Cneorum*, *C. althæoides*, *Tradescantia virginiana*, *Dryas octopetala*, *Antennaria*, *Thalictrums*, *Anthericum ramosum*, *Achilleas*, *Delphiniums* (in variety), *Eremuri*, *Hyacinthus candicans*, *Gladiolus* (many varieties), *Œnotheras*, *Meconopsis* (in variety), *Phloxes* (herbaceous), *Alstræmerias*, *Anchusas*, *Galegas*, *Verbascums*, *Eupatoriums*, *Eryngiums*, *Eryngiums*, *Acanthus*, *Galegas*, *Chrysanthemum maximum vars.*, *Tritomas*, *Lupins*, *Aquilegias* (in variety), *Scabiosa caucasica*, *S. atro-purpurea*, *Bergamot*, *Linums*, *Sweet Williams*, *Nepeta Mussini*, *Liliums* (in variety), *Foxgloves*, *Centaureas*, *Helianthus*, *Salvias*, *Coreopsis* (in variety), *Lobelia cardinalis*, *L. ramosa*, *Pentstemons* (in great variety), *Antirrhinums* (in many colours), *Gazania splendens*, *Carnations*, *Sweet Sultan*, *Candytuft*, *Petunias*, *Verbenas*, *Gypsophilas*, *Leptosiphons*, *Stocks* (in variety), *Mignonette*, *Tufted Pansies* (in variety), *Godetias*, *Clarkias*, *Calceolaria amplexicaulis*, *C. mexicana*, *C. Burbidgei*, *Aperatum*, *Heliotrope*, *Pelargoniums* (in variety), *Anagalis*, *Phlox Drummondii*, *Nemesios* (in variety), *Dianthus Heddeiwigi* (in many colours), *Sweet Peas*, *Senecio japonica*, *S. Clivorum*, *Iris* (in variety), *Primulas*, *Hemerocollis* (in variety), *Lythrum roseum*, *Epilobium pedunculare*, *Lysimachias*, *Solidagos*, *Sagittaria sagittalis*, *Aponogeton spathaceum*, *Water Lilies* (in variety).

THE WEEK'S WORK.—*Antirrhinums* planted in groups of separate colours are now making a fine show. To ensure a succession of bloom the old flower-stems are cut off as soon as the blooms have fallen. If this is attended to lateral growths develop and a succession of flowers is maintained. If the seed capsules are retained the plants will at once cease blooming. *Pentstemons* are also making a grand show. In order to extend the flowering season as long as possible the plants are watered frequently during dry weather, using diluted liquid-manure occasionally. Herbaceous plants that have passed out of bloom have had their flower-stems removed down to the fresh leaves. If possible to keep these well watered during dry weather many will flower a second time. *Anemone coronaria*, having died down, the tubers have been lifted and stored in boxes of dry sand to be planted in fresh positions at the end of September. English and Spanish *Iris* that are nearing the ripening stage have also been lifted. Frequent hoeing and weeding are necessary. *Myosotis* and *Alyssum saxatile* raised in boxes have been pricked out in nursery beds on a border. *Meconopsis integrifolia* and *M. Wallichii*, raised from seed sown last March and pricked out into boxes as soon as large enough to handle, have made good progress, and have now been potted singly into 5-inch pots and placed in a shady position out-of-doors. These will be kept in a cold frame through the winter, and planted where intended to flower next spring. Many plants in the rock garden are now ripening their seed pods, and the gathering of these requires attention almost

daily. Select the seeds from plants with the best coloured flowers and the best habit of growth.

F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Kales.—These should be planted now. There are now so many superior varieties in commerce that no one would think of growing the sorts which were formerly favoured. The ground for Kales should be in good heart; if not firm it should be made so by trampling the surface before planting takes place. The plants may stand 18 inches apart in the rows, but they succeed better and withstand severe weather with less risk if accorded another 6 inches. The rows would be quite close enough together if they stand 2 feet apart.

Savoys.—These are always useful when cold weather sets in, and the supply of other green vegetables begins to run short. A good quantity of maincrop and late varieties should, therefore, be planted now on firm and, if possible, heavy soil, as the finest beads are developed under these conditions. The larger-growing varieties, such as *Best of All* and *Drumhead*, require the same space as Kales. To succeed the two last-named sorts plant *Late Drumhead*.

Shallots.—These should be lifted and laid out on mats or shutters placed somewhere in full sun to get the bulbs thoroughly dry and mature before storing them.

Early Potatoes.—The remainder of the crop will now be the better for being lifted, when requirements in the way of seed tubers for another season should have attention by selecting the requisite quantity and laying them out thinly in the store or on the floor of a shed to become properly matured.

Second earlies and late sorts.—The first-named have done well this season, and crops promise to be, judging by examination of a few stems, very heavy. Maincrop and late varieties also look well, growth being more satisfactory than it has been for several years past. Moulding has been completed, and the chief thing now is to keep down weeds until the tops have developed sufficiently to smother them. All big weeds are best pulled by hand and burnt.

Mushrooms.—Manure should now be obtained and prepared for the making of a bed about the middle or end of next month. In many places the supply has to be procured from livery and other stables in the nearest town. This usually contains a large percentage of straw, but this can be shaken out. Then if the residue or droppings are partly dried, if necessary, by spreading them out thinly on the floor of an open shed, and afterwards thrown together to ferment in the usual way, excellent returns result in due course from the use of such material. Manure from stables where carriage horses are still kept or from farm stables is, of course, equally as serviceable, provided in the latter instance the horses are not given quantities of green food. In that event the manure is useless for the purpose. In the meantime the Mushroom-house, if it is situated in a cool, shady position or on the north side of a wall, should be cleansed, disinfected by burning sulphur in an old bucket or similar receptacle in sufficient quantity to fill the structure with fumes, and then lime-washed. This gets rid of insects and any germs there may be present on wood-work, etc., and renders all sweet and clean for a start. When the temperature of the house is yet too high for a bed to be made up, a suitable place can usually be found in a shed or disused stable. Spawn in sufficient quantity should be purchased, and be ready to hand a few days before it is required. Any remaining over from last spring may be used or mixed with the new, but should not be relied on altogether.

Perennial Lobelias.—Where these are appreciated the present is a good time to raise young stock from seed. This should be sown and germinated in the same way as herbaceous *Calceolarias*. When large enough to handle, prick off the seedlings into pans or boxes and afterwards transfer them to 60-sized pots. If given frame or cold-pit culture they make nice

plants by the end of autumn, and may be planted out in the borders where required in the spring. A position such as a shelf in a cool greenhouse suits them best during the winter.

Coreopsis grandiflora.—No flower borders are complete unless this showy subject is represented in good-sized clumps. Seed, if sown now in a box and raised in a frame, quickly furnishes an abundance of plants, which if pricked out as soon as ready in good soil become fit for setting out in the borders in November, or they may be left till February and then planted in their permanent positions.

Canterbury Bells.—These should be pricked out at once to the required quantities in lines 1 foot apart, allowing a distance of 9 inches between the plants. Kept clear of weeds with an occasional stirring of the soil with a hoe between the rows, and watered when necessary, strong plants will result by the end of October. The double or cup-and-saucer varieties are charming subjects for flower borders, and have made a grand display this season. The single kinds are more suited for employment in the wild garden or for planting in Grass.

Malmesbury Carnations.—Directly the last of the blooms has faded the best of the young plants are picked out and set on one side for shifting into large pots to be grown on into specimen plants for another season. The remainder will then be layered to afford plants for growing on in 5-inch and 6-inch pots, from which specimen blooms (one each) will be taken next year. The layering is carried out in a low pit containing a bed of soil in which the balls are laid on their sides. The surface is then covered with a sufficient depth of suitable sandy compost for the layers to be pegged into. As the layering progresses the sashes are put on and shade afforded during the day. A sprinkling is given overhead daily in fine weather, and when rooting commences the pit is aired and shading dispensed with.

Callas.—Although the weather has been so sunless for some time past these have ripened up well and have enjoyed a fairly long period of rest. The tubers will now be shaken out and repotted, all the strongest and best being put into 10-inch pots and the weaker into pots of a less size. The compost consists for the most part of good fibrous loam of a holding nature. The additions are leaf-mould, a little rotten manure, lime rubble, and coarse sand. When finished the pots will be stood in a corner of the Chrysanthemum ground.

Poinsettia pulcherrima.—The early-struck cuttings should be shifted on into 6-inch and 7-inch pots, and another or third batch of cuttings got in for late flowering. These should be inserted singly in thumbs and placed in a propagating case to root. A. W.

MIDLAND COUNTIES.

Late Grapes.—So far, the present season has not been favourable to Grapes in late houses, and these will need plenty of encouragement in order that they may ripen perfectly. Late Muscats and Lady Downe's especially are difficult to ripen unless the season is favourable. Where the roots are confined to the inside of the house the trouble is greatly lessened. The bunches must be exposed fully to the light; therefore, if there is a thick covering of foliage, this should be drawn aside to allow the sun's rays to penetrate amongst the branches. Laterals must be removed before they become large, as the removal of a great quantity of growth at one time tends to paralyse root-action. Keep a brisk heat in the pipes except when the weather is hot, and do not allow the temperature to drop below 68 degs. until the Grapes are ripe. Give close attention to the watering of the borders, and when necessary choose a time when the ventilators can be opened fully.

Strawberries.—Young plants that were layered early will now be ready for severance. After cutting them off the parent plants they should be placed in a shady position for a few days to recover from the check, and afterwards planted in their permanent quarters without delay. A plot of land which was trenched and manured last winter and from which a crop of early Potatoes has been taken,

is being prepared for the main crop of Strawberries. After levelling the soil, a good dressing of soot and wood ashes is worked in, afterwards making the ground firm. In the main plantation it is necessary to leave a space of 2 feet between the rows, and 1 foot from plant to plant in the rows. In the following season, after the fruits have been gathered, every alternate plant is removed. When planting make the soil very firm, being careful to keep the crown of the plant just above the surface. After planting is finished give a thorough watering. The subsequent treatment consists in cutting off all runners as they appear and keeping the ground clean by constant hoeing.

Black Currants.—When the crop has been gathered the branches will be well thinned out to encourage the young growths from the base. If the bushes are thinned now these young shoots will ripen much better and earlier. All prunings should be burnt in order to destroy any insect pests that may be on them.

Sweet Cherries.—As the trees are cleared of their crops the shoots are stopped and the trees given a thorough washing with Quassia extract to destroy black aphid, which has been very troublesome.

Fig-trees on a south wall are in full growth and bearing good crops of fruit, but unless there is soon a change in the weather the fruits will fail to ripen. The shoots have been thinned down to a moderate number.

Lilium speciosum.—This is now blooming freely. As soon as the flowering season is over the bulbs will be placed in the open for the purpose of ripening them. A quantity of retarded *Lilium longiflorum* has just come to hand. The bulbs have been removed from the packages and placed in single layers in shallow boxes filled with sand. At the first opportunity the bulbs will be potted up singly into 6-inch pots, using a compost of three parts good fibrous loam, one part leaf-soil, and manure from a spent Mushroom bed, with sufficient coarse sand to render it porous. When potted they will be placed in a cool frame and covered with leaf-soil until they commence to grow. When well rooted, batches are introduced to heat as required. Cuttings of *Hydrangea hortensis* have been inserted in a frame to furnish single-stem plants for next year. Fairly hard shoots are selected and made very firm in the soil. After one good watering slight dampings overhead daily provide sufficient moisture until they are rooted. So far, the present season has been one of the most sunless experienced for some time past. In consequence of this, many of the crops are not nearly so satisfactory as they once promised to be.

Runner Beans promise to be good, although, like many other crops, they are very late. The leading growths should be kept trained to the supports, cutting away any surplus laterals. During dry weather the roots must be kept well supplied with water. A sowing of

French Beans will now be made in a frame to provide supplies late in the autumn. Protection from frost is necessary for this, but no artificial heat. The bed of the pit is dug deeply, and a quantity of manure from a spent Mushroom bed mixed with it. Make the soil moderately firm, and draw the drills at 18 inches apart, placing the seeds at 6 inches apart in the drills, and covering them with fine soil. Dwarf-growing varieties are chosen for this crop. The lights are removed from the pit until the weather becomes cold, when they are placed in position.

Seakale.—The crowns on plants grown specially for early forcing have been reduced to one, and every possible care taken to encourage the building up of stout, well-ripened crowns by the autumn. The surface of the soil is frequently stirred with the hoe, and during showery weather occasional applications of guano afforded.

Turnips.—The final sowing of Turnips will be made during the first week in August. The ground intended for this crop should be well manured to promote a quick growth, thus assisting the plants the better to withstand the attacks of the fly, which in some seasons prove so destructive. The early crops of Peas being now over, the plants have been

cleared, and the ground prepared for sowing winter Spinach.

Herbs are in demand during the winter. A quantity of most of the varieties, such as Sage, Marjoram, and Thyme, should be cut and carefully laid out to dry in a sunny position, afterwards tying them in small bunches and suspending in an open shed.

F. W. GALLOP.

SCOTLAND.

Vegetable garden.—In the early part of the week work was again interrupted by heavy rains, which, in conjunction with cold and sunless weather, make the outlook a little discouraging. Conditions improved about the middle of the week, and although the soil was rather wet, an endeavour was made to get rid of the weeds, which, suited by the weather, had become rather numerous. Hand-weeding was, of course, necessary, a method which, if slow, is sure, and when the surface was thoroughly clean the hoe was run through the soil to aerate it as much as possible. A young hare having found its way into the garden caused some destruction before its presence was noticed, and it became necessary to beat up a considerable number of different kinds of Brassicas out of which it had nipped the hearts. The intruder was promptly dealt with, and a look round for further damage revealed that a line of Spinach Beet just germinating had been neatly eaten over by the ground line. Resowing was done without delay, and at the same time a breadth of Prickly Spinach was sown. A good substitute for this at times disappointing vegetable may be found in Curly Kale, and to ensure a plentiful supply a line of some length was sown with seed saved from a plant or two for this purpose. Further sowings of Cabbage seed for providing material for autumn planting were made, a finish was made with the planting of Leeks, more Turnips were thinned, and a final sowing made. Suited by the rainy weather, Celery is making rapid progress, and the plants were relieved of side-shoots during the week. French Beans are noticeably later than usual from out-of-door sowings, as are Globe Artichokes. The last, however, are now of a usable size, and a very good crop. As it was too wet to sow Parsley out-of-doors in the beginning of the week, a sowing was made under glass in a box, the seedlings of which will be pricked off into their permanent quarters as soon as they attain to sufficient size. Lettuces are now sown where they are to grow, as the season is rather advanced for transplanting. A further allowance of artificial manure was given to Asparagus, which is making excellent growth.

Pentas rosea.—The batch of this useful hard-wooded stove plant, which is intended for early-winter blooming, has gone into flowering pots. These are chiefly 6 inches in diameter—a size sufficiently large for the requirements of this subject. The rosy *Bouvardia*-like blooms are freely produced, and while the plants cannot be said to be symmetrical, even when frequent pinching is practised, yet the stiff, long stems of the trusses of bloom render them valuable for cutting. When the roots fully occupy the pots a little weak stimulant will be given, and, meantime, as aphid is inclined to be troublesome on the tips of the shoots, the plants will be regularly syringed until the trusses are on the point of expanding. *P. rosea* is grown in the stove, and it blooms uninterruptedly throughout the winter and spring months.

Early-flowering Chrysanthemums.—The heavy rains having somewhat knocked about these, some time was devoted to staking them and tying them. Rain is at times more to be dreaded than gales, the weight of the water which accumulates on the foliage being apt to snap off the succulent and brittle stems. For staking, Bamboo canes are used. These are not unduly obtrusive after growth is some way advanced, and are very durable, lasting without rotting for a number of seasons.

Pot Chrysanthemums.—Not for some seasons has the growth of Chrysanthemums for winter decoration been so satisfactory. There has, so far, been an entire absence of pests of any kind, although there is always

some danger from earwigs at a later date. Although the rainfall has been excessive, yet daily inspection is given to these plants. It is never safe, I think, at this time to trust to the rainfall being sufficient for the wants of these plants on any wet day, for it will be noticed that the robust foliage sheds the water off. No plant suffers more quickly or is more easily damaged by a lack of moisture than the Chrysanthemum. Staking is being done at intervals when time can be spared.

Summer pruning.—A certain amount of summer pruning was done during the week, the trees attended to being Pears. The crop is more satisfactory than was at one time anticipated, some trees needing rather severe thinning. In the case of trees which have filled their allotted space the pruning is simple, merely consisting in shortening back the breast-wood and regulating the ties of the shoots. The latter point is, I fear, sometimes overlooked at the time of summer pruning, and an overtight ligature if not attended to at this time may result in damage to a shoot or a branch before the regulation pruning-time comes with the closing year. In the case of foliage which obscures promising fruits, no objection can be made to its removal, although wholesale defoliation is deprecated. In the case of Pear-trees which are grafted on Quince or other stocks, any suckers which may have made their appearance ought to be promptly removed. It is better, when possible, to twist these off at their junction with the stock, otherwise they are apt, if cut, to come away more strongly from dormant eyes. Such trees as have not been already mulched were attended to as seemed to be necessary, and trees which are not this year bearing a full crop were by no means neglected. It always appears to me to be bad policy to pass over a tree with scanty attention merely because it has missed a season. If such a tree is neglected how can it be expected to give a good return in the following year?

Peaches and Nectarines.—Thinning has now been completed in the case of Peaches and of Nectarines on the walls, and a beginning was made with the tying in of the young wood, the fruits being exposed as much as possible to the sun's rays. The crops are, in respect of number, quite satisfactory, and if the weather improves at an early date, progress will be rapid. In a general way, the fruits of Hale's Early Peach usually ripen in the early days of August, but they will most probably be a little later during the present season.

Stove.—This house may with advantage be now freely ventilated on all suitable occasions in order to ripen up the growth. This ventilating is especially valuable in warm weather, the soft air circulating among the plants being of much benefit. It also tends to check insect pests, thrips being at times troublesome among fine-foliaged plants. Gloxinias are very effective just at this time, and brightly-hued foliage is at all times attractive. Some small plants of different subjects which appeared to need a shift were moved into larger pots. Owing to the low temperature out-of-doors, it became necessary at times to light the fire, but as soon as possible it was again dispensed with. Syringing is being regularly done, soft water from the rain tanks always being used.

Schizanthus Wisetonensis for winter flowering was pricked off during the week. A departure was made from the usual way of sowing this seed. It was noticed in spring that numerous seedlings made their appearance on a stage covered with crushed granite upon which a batch of plants had been grown. These seedlings were stronger and more robust than others from a more orthodox sowing, so some time ago a pinch of seed was scattered over the granite on the stage. Germination has been free, and a sufficient quantity of stout young plants has been secured.

Alonsoa incisifolia.—A sowing of this bright and useful annual has been made for winter flowering. The scarlet sprays of this are very telling, and they are freely produced. No doubt, the habit of *A. incisifolia* is rather straggling, but this can be corrected by occasional pinching while the plants are in their younger stages.

Rose blooms are suffering from the wet. On the other hand, growth is good, and there is no trouble with insects. A watch is being kept for a possible outbreak of mildew, which is not unlikely to occur should a period of close and hot weather follow the late rains. A dusting or two of flowers of sulphur soon disposes of mildew if applied in its earliest stages.

Hardy-flower borders, too, have suffered from the excessive wet. Nevertheless, they are very attractive at the present time. The latest additions include the different varieties of *Anthemis*—a family which is not only bright in itself, but of long duration. A good *Woodruff* is to be found in *Asperula hexaphylla*, the neat *Gypsophila*-like blooms being useful in conjunction with Sweet Peas. *Stenactis speciosa* is showy, the Aster-like blooms being so useful for cutting. Rather prematurely, some colonies of the *Kaffir Lily* (*Schizostylis coccinea*) are in bloom, probably due to the dripping weather. W. McGurrog.

Balmac Gardens, Kirkcudbright.

NATIONAL CARNATION AND PICOTEE SOCIETY (SOUTHERN SECTION).

JULY 20TH, 1916.

COMPARATIVELY few exhibits were staged on the occasion of the annual show on the above date, held at the Royal Horticultural Hall, the entries being far below those of former years. To some extent, doubtless, the weather immediately preceding the show was responsible, cold nights and sunless days being alike unfavourable to the development of the flower. At the same time, it has to be stated in fairness that rarely have finer flowers been staged in the more important classes, those "open to all." In not a few of these, flowers of the highest cultural excellence were seen, for which no praise would be too great, and, arranged with much natural effect, practically made the show. Cut with full-length stems, judiciously garnished with "Grass" and unopened buds, these vase classes were worthy the best aims of any Society, while doing full justice to the flower itself. We say this much advisedly, in view of the flowers shown in those other classes on cards and boards, whose mutilated remains, attracting nobody, still appear to receive some measure of encouragement from the Society. For such as these, relics in part of a bygone age and as useless in the home as they are valueless in the garden, we have not the smallest sympathy. The part, too, they so poorly play in the exhibition hall could be far better filled with other and more useful sorts. The attention of the Society should also be directed to the neglect of certain exhibitors—one in particular—to name their flowers, despite the requirement of Regulation II. that "all exhibits must be legibly named." The educational aspect of an exhibition is held to be a matter of some importance, and neglect to name exhibits considerably nullifies it. The Martin Smith Memorial Cup was won by Mr. H. W. Frostick, Norbury, S.W., the Cartwright Challenge Cup being won by Mr. Douglas, who, as usual, was one of the chief prize winners. Sub-joined are some brief details of the leading exhibits.

FLOWERS IN VASES (FIRST DIVISION).

For four varieties selfs, three of each, Mr. J. Douglas, who was first, showed *Daffodil* (yellow), Mrs. G. Jones (rich apricot), Mrs. G. Marshall (maroon), and Fujiyama (scarlet). Four fancies other than white ground, first, Mr. Douglas, his set being *Mona*, *Pasquin*, *Linkman*, and *Edenside*. In the white ground class, similar conditions, Mr. Douglas had *Fair Ellen* (whose ground colour of exceptional

purity is touched with lavender), *Othello*, Mrs. P. W. Owen, and *Lord Kitchener*. Mr. Lakeman was second in each of these, none of his flowers being named. Mr. Douglas also led in the important class for nine distinct varieties selfs, fancies, and yellow ground *Picotees*, three in each vase, his set including *Lt. Shackleton*, *Lord Steyne*, *Fujiyama*, *My Clove* (pink, delightfully fragrant), *Her Majesty*, and Mrs. G. Marshall (maroon).

FLOWERS IN VASES (SECOND DIVISION).

In this Mr. H. W. Frostick, Norbury, who carried off the Martin Smith Challenge Cup, was the chief prize winner, securing firsts respectively for white ground *Picotees*, yellow selfs, and other colour (selfs), showing *Miss Rose Josephs*, a remarkable variety of antique rose, and for six varieties, selfs, fancies, and yellow grounds, three of each. In this last his set comprised *Gordon Douglas* (maroon), *Onward* (yellow *Picotee*), *Linkman*, and *Lord Steyne* (very fine), fancies, and *Bookham White*. Miss Shiffner won firsts for white selfs, showing *Bookham White*, scarlet selfs, with *Fujiyama*, terra-cotta selfs, showing *Elizabeth Shiffner*, and for yellow or buff ground fancies in which *Lt. Shackleton* (freckled with rosy-scarlet) was shown. Mr. J. Fairlie, Acton, showed *Persephone* (scarlet) and *Heliotrope* (fancy) in Class 25, and took first against seven competitors. The variety is very distinct and of outstanding merit.

DIVISION IV. (OPEN TO ALL).

This includes Classes 40 to 49, the Cartwright Challenge Cup being awarded to the best exhibits of any one exhibitor. The exhibits in these, as already hinted, practically made the show, though we could have desired a less free use of wire supports in some of them. Nine blooms, one variety, in a vase were asked for in each. In pink or rose selfs Mr. Lakeman led with *Rosy Morn*. White selfs: Messrs. A. R. Brown, Limited, King's Norton, were first with a superb lot of *Prairie Belle*, its petal quality very fine. A bloom in Mr. Lakeman's stand was selected for Premier. The last-named exhibitor took first for maroon selfs, having Mrs. G. Marshall (very fine), Mr. Douglas showing *The King* and gaining second prize. Mr. Douglas and Mr. Lakeman achieved success in the order named for yellow selfs, both showing *Daffodil*; also for scarlet selfs, both showing *Fujiyama*, which is of a glowing red colour. For buff or terra-cotta Mr. Douglas gained first prize with a handsome vase of *Elizabeth Shiffner*. For "any other colour" Mr. Lakeman was first, having *Miss Rose Josephs* (antique rose), the most distinct variety probably in the whole show, a telling colour wedded to fine quality. Mr. Lakeman again led for nine yellow ground *Picotees* with *Onward*, a light-edged variety. A bloom of this was selected as Premier. In yellow ground or buff fancies Mr. Douglas and Mr. Lakeman both showed *Pasquin*, a grand flower of the first-named lot, which was awarded first prize, being selected Premier. This is one of the finest fancies. Three others in this class showed *Linkman*. Nine fancies other than yellow or buff ground, Mr. J. Douglas took first with *Fair Ellen*, a novelty in white fancies head and shoulders above all else. Lightly-pencilled lavender on a clear ground of dazzling whiteness, the contrast is particularly good. It was also awarded Premier. Classing *Miss Rose Josephs* as the most distinct variety shown, we should characterize *Fair Ellen* as without a peer among varieties of the highest class to-day.

BOOKS.

"A WOMAN'S HARDY GARDEN."*

THERE are signs that the American country people are becoming much more interested in their hardy and native flowers. They have what is, perhaps, one of the noblest of known flora, and many years before they thought of the wild flowers some of them were much grown and loved in the British Islands, where they did very well. One of the busiest of writers about the American flower garden is Mrs. H. R. Eley, whose garden is on the hills of New Jersey. It is a great advantage that people should know what they write about. There is so much difference between our climate and that of eastern America that, as regards planting, there is not much to be said that would be profitable either way. Gardening must always be a matter of local observation, and the conditions in America are so different from ours that we must have quite different plans. The American summer is too hot for the full enjoyment of hardy plants, and their great advantage over us is in their shrubs, which ripen their wood so well that the flowering is profuse and beautiful.

The illustrations in this book are numerous and very often good, but spoilt by over-emphasis of the blacks. The printing of the letterpress is good. Mrs. Eley has written some excellent and stimulating books on the subject of hardy plants in America, and they are not without touches of humour.

With work in the garden care and worry vanish. The cook (as some cooks of mine have done) may announce that "'tis a woild waste of a place. I be lavin' the mornin'." The hamper of meat does not arrive on the one train from town, or somebody smashes something very dear to your heart—just go to the garden, tie up some Roses or Vines, or poke about with a trowel, and though murder may have been in your thoughts, in half an hour serenity will return. And what does it all matter, anyway? Another maid can cook for a few days, and there are always bacon and eggs. Philosophy is inevitably learned in a garden. Speaking of eggs, I think of hens. Living on a farm, of course, there have always been hens and chickens. These creatures were provided with houses and yards and fences, and given every inducement to remain where they belonged; yet with diabolical ingenuity they would escape from their quarters, dig under the fence, fly over it, or someone would leave a door or a gate open, and then, with one accord, all the flock would make for the gardeus and scratch and roll in the borders. But the limit of endurance was reached when, one afternoon, coming out to look at a bed of several dozen Chrysanthemums set out in the morning, I found the poor plants all scratched out of the ground, broken and wilted. Then in wrath the fiat went forth, "No more hens on this farm, those on hand to be eaten at once." For days a patient family had hen soup, hen croquettes, hen salad and hen fricassee, until the last culprit came to her end.

"THE BOOK OF OLD SUNDIALS AND THEIR MOTTOES."†

This is printed on toned paper, and has eight illustrations in colour by Mr. Alfred Rawlings, and some thirty-six drawings of famous sundials, in black and white, by Mr. Warrington Hogg. The sundials are found at churches in various parts of the country, in museums, at country houses, and over shops (such as one at Rye). Mr. Launcelot Cross writes a sympathetic description, extending to some twenty pages of letterpress, of old sundials. The greater portion of the work is given up to the mottoes of sundials,

* "A Woman's Hardy Garden," by Helena Rutherford Eley. London: Macmillan and Co.

† "The Book of Old Sundials and Their Mottoes," T. N. Foulis. Price 3s. 6d.

which are set out in old-fashioned type. The motto chosen by Queen Alexandra for the sundial at Sandringham occupies the first position. It reads: "Let others tell of storms and showers, I'll only count your sunny hours." The binding of the book is hideous.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Black-spot on Rose-leaves (*F. S. Iredale*).—The leaves you send have been attacked by "black-spot," a very troublesome fungoid disease, which is very prevalent on some sorts this season. We should advise you to spray the plants with Woburn Bordeaux paste, both now and throughout the season at intervals. It will be most effectual, however, if you commence to spray another year as soon as pruning has been completed. Be careful to burn all prunings and all decayed foliage. We do not reply to queries by post.

Oleander not flowering (*S. M.*).—It is very probable that the trouble with your Oleander results from insufficient moisture and feeding, as if properly drained it is hardly possible to give too much water. A dose of liquid manure about every fortnight during the summer will also greatly assist the development of the flower-buds and prevent them dropping. A genial atmosphere during the growing season is important, while during the summer the plant may be stood in the open air to thoroughly ripen the wood, on which successful blooming in a great measure depends.

Begonias unhealthy (*S. Lamb*).—The injury to your Begonia leaves is due to yellow thrips, insects so tiny that it is very difficult to see them. True, we could not find any insects on the leaves sent, but the damage is done when the leaves are young, and as the leaves grow the disease develops. An unduly dry atmosphere is the principal cause of the trouble, and the best remedy is frequent vaporising and maintaining a fairly moist atmosphere. It is of no use attempting to restore any plants so badly affected as the pieces you send us, and the best plan will be to clear them out into a frame and dry them off, gathering up and burning all the shoots and leaves.

Eccremocarpus scaber (*H.*).—In this we have a delightful creeper that is not often seen, notwithstanding it flowers long and freely during the summer months. The plant may not prove perfectly hardy in all parts of England, though in the southern and western districts it grows freely and flowers every year. The best position for it is against a wall, facing south or south-west, its orange-red flowers being very beautiful. It may be raised from seed early in the year, and planted out in May. In such a soil as yours we should prepare a place for it by substituting some loamy sandy soil and plenty of drainage for the clay. Give the plant the warmest nook you can find for it, and cover the roots with ashes or cocoa-fibre before the advent of hard frosts. Treated thus, even if it gets cut down to the ground, it will send up shoots from the root stock in the spring. If you plant it against a wall you will have to nail it up, but a better way would be to fix some Pea-sticks in the ground and lean them against the wall, allowing the plant to ramble at will among the sticks.

FRUIT.

Apples cracking (*A Reader*).—The only reason we can suggest for the cracking of your Apples is that the roots have gone into the poor sandy soil of which you speak. When that happens a fungus which preys on the ill-formed fruits and spoils them is set up. We should advise you to try, in the autumn, hard root-pruning, treating one side of the tree only. Cut off all downward roots so as to encourage the formation of new and fibrous roots on the surface. It is then that a mulch of rotten manure will be beneficial. Cox's Orange Pippin is very subject to canker, and it is just possible that such may be the case with the trees you refer to.

VEGETABLES.

Caterpillars on Cabbages (*Mrs. Cornish*).—We fear there is nothing you can do to prevent the white butterfly laying its eggs on the Cabbages. On the first signs of the caterpillar then hand-picking is the only remedy, but if the caterpillars are very numerous, syringe the plants with mildly-salt water, and soon after give a heavy washing with clear water. Dustings of fine salt applied over night and washed off with clear water in the morning often do much to destroy the caterpillars.

SHORT REPLIES.

Wm. Paul.—The truss of bloom had fallen to pieces, and it was quite impossible to form any idea as to its value.—*Miss Lushington*.—We do not now undertake *post-mortem* examinations. These were discontinued some few years ago.—*Mrs. R. M. Riccard*.—Seeing you give us no particulars as to the soil and the cultivation of the plants, it is quite impossible to suggest any cause. We should advise you to ask a practical man to visit the garden, and who by doing so could find out the cause and suggest a probable remedy.—*D.*—If, as in London, the weather with you has been dull, with little sunshine, the flowers open but slowly and bursting of the calyx follows. Some varieties are far more liable to burst than others.—*E. J. H.*—See reply to your query in our issue of July 29th, page 379.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*E. L. B.*—1, *Phacelia campanularia*; 2, *Gilia tricolor*; 3, *Dictamnus Fraxinella albus*; 4, *Papaver nudicaule*.—*F. F.*—1, *Pteris serrulata*; 2, *Pteris serrulata cristata*; 3, *Asplenium bulbiferum*; 4, *Pteris tremula*.—*A. Walker*.—1, *Escallonia macrantha*; 2, *Begonia Dregei*.—*R. W.*—1, *Thalictrum adiantifolium*; 2, *Hemerocallis flava*; 3, *Begonia fuchsoides*.—*E. D.*—1, *Arum Dracunculus*; 2, *Fuchsia procumbens*; 3, *Crucianella stylosa*; 4, *Centaurea montana alba*.—*A. W. A.*—1, *Sedum album*; 2, *Cistus ladaniferus*.—*Fernside*.—1, *Sempervivum* sp., probably *S. Haworthi*; 2 and 3, White-flowered forms of *Helianthemum vulgare*; 4, *Rhodiola rosea*.—*A. M. L.*—A, *Sidalcea malviflora*; B, *Epilobium hirsutum*; C, *Borago (Borago officinalis)*; D, A fine form of the Purple Loosestrife (*Lythrum Salicaria*).—*Mrs. Stewart*.—Fine, fully-blown Roses travel very badly, and yours were all fallen. We see the remains of Caroline Testout (pink), Hugh Dickson (red), and a beautiful Rose that looks like a big Malmaison.—*Tweedside*.—1 and 2, To name Ferns properly we must have spore-bearing fronds; 3, Specimen insufficient.

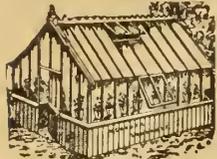

Name of fruit.—*F. Parker*.—Sorry we are unable to name the Gooseberries you send, as it is all important that the habit of the plant should be known.

OBITUARY.

N. N. SHERWOOD.

WE regret to announce the death, at the age of seventy-one, of Mr. N. N. Sherwood, at his country residence, Prested Hall, Kelvedon, Essex, on July 20th. Mr. Sherwood was the head of the well-known firm of Messrs. Hurst and Son, of Houndsditch, and his name will long be cherished for the great interest he took in all the gardening charities. For many years he was treasurer of the Royal Gardeners' Orphan Fund, a trustee of the Gardeners' Benevolent Institution, and to him we owe the inception of the Convalescent Fund of the United Horticultural and Benefit Provident Society, to which he annually sent a donation. He was one of the original recipients of the Victoria Medal of Honour. In 1902 Mr. Sherwood suffered from a very severe illness, owing to which he was compelled to hand over the management of the business to his two sons, William and Edward Sherwood, who since then have been entirely responsible for its direction.

NOTICE TO ADVERTISERS.
As we have to print a large edition of GARDENING ILLUSTRATED, it is essential that advertisement copy should reach us not later than the Friday morning for the issue of the week following.
We commence printing on Friday, and no advertisement can be altered or stopped after first post on Friday morning.
GARDENING ILLUSTRATED is obtainable on the Wednesday preceding the date shown on the paper.
63, LINCOLN'S INN FIELDS, LONDON, W.C.

READERS will oblige by mentioning GARDENING ILLUSTRATED when answering advertisements. Business firms are always pleased to hear from our readers.

MACHINE WORK IN GARDENS.

UNDER this heading in a recent issue of *The Times* some advice is given about introducing a motor-driven machine into our gardens—a very unwise suggestion. To keep the smell and noise of the motor out of the garden is the best way for most of us, who get enough of motors in other ways. The right plan is to refrain from mowing Grass as much as possible in these days of labour shortage. In the past hundreds of acres of pleasure ground, which would have been much better left alone, have been mown. It is much better to let the early flowers grow in the Grass. Mowing should be confined to essential needs of the garden or playground. All needed in most places could be done well by one man with the lightest of hand mowing machines, and so get rid of the horse or the motor in the garden. I have left my lawn unmown this year and cannot even mow it in the hay time. I lose the hay and can only turn the crop into mulching stuff when I have the labour to do it, but that is better than the alternative of mowing it with a motor.

Then the writer of the article introduces the blow lamp for destroying weeds, but that is snrely not nearly so effective or quick in action as a good weed-killer.

As to sweeping up leaves as they fall, a better way is to let them all fall before sweeping them up, and then gather them up in the old way and turn them into leaf-mould. Hitherto there has been much needless fuss over the sweeping up of the fallen leaves.

In most places all but bereft of skilled men, owners will be well advised to call to their aid every labour-saving device they can afford that may help them to tide over the very tight place in which they find themselves.

Just now when lawns that in many cases have been carefully tended for generations are in danger of going to seed, the usefulness of the mower would be increased tenfold by the evolution of a simple motor-driven machine, smaller and handier than those at present available, and marketed at a price within the powers of the man of moderate means. Meanwhile, where there is much Grass to be cut in straight-forward fashion those who possess a small light car geared to crawl at five miles an hour or less, will find that by taking the mowing machine in tow, work that usu-

ally occupies some hours can be done in a fraction of the time. Half-an-hour's practice should be enough to establish a working understanding between the man or woman at the wheel and the individual guiding the mower. The inevitable wheel marks will soon disappear.

Those who understand the handling of such things will find that a paraffin blow lamp of the kind employed by house painters for removing old paint makes a wonderfully effective weed destroyer, burning up tops and roots beyond recovery, and at far less cost than where poison is used. In the kitchen garden revolving cultivators deal with weeds as effectively as the Dutch hoe and in less than half the time.

Later on, when growth goes to rest and leaves cumber the ground gardeners will find leaf-sweeping machines of great use.

These changes are quite in the wrong direction and may do infinite harm. There is no need for machine work in the garden, and all the difficulties of the day in the garden may be got over by simpler means.

WALKS AND DRIVES.

The greatest improvement ever made in the keeping of gardens was the introduction of the weed-killer, and the "blow" pipe as suggested here would be a poor substitute. One mile of my drive, 15 feet wide, has been kept in order for several years now at a seventh part of the cost of the old way of ripping up and scuffing the drive. One dressing a year of Bentley's weed-killer is usually applied in August if weather permits, and its use saves much labour to turn to a better end. The amount of labour wasted on walks and drives in the past was great. Ripping up the walks was the rule in British and Continental gardens. A horse with a sort of large hoe was used in large parks abroad, and all this waste of energy to make a seed-bed for future generations of weeds. To get rid of the horse and his boots in mowing was a gain, and it is quite easy to get rid of mechanical aids in the garden; above all, those depending on the filth of petrol and its allies. The light and well-made American hoes and "cultivators" are useless on much of our heavy land, though well worth looking after on suitable soils.

The needless excess of walks in many gardens doubled the labour. This often resulted from the adaptation of office-made plans to ground inviting simpler design. A yard of walk not needed for the work and convenience of a place should not be made.

W. R.

NOTES OF THE WEEK.

Delphinium grandiflorum Azure Fairy.—This gives a cloud of pretty colour in a group; a lovely pale blue.

Rose harmonies.—You have, of course, made the acquaintance of the climbing Rose, American Pillar. It is good in constitution and good in effect when seen at a distance on the side of a house or down a bank, and even in combination with Lady Gay, which is lighter in colour, but distinctly free-flowering. They both flower at the same time.—R. H. B.

Antirrhinum.—With reference to the illustration of Antirrhinum in your issue of the 29th ult. (p. 373) I feel sure a mistake has been made in naming this Antirrhinum Asarina. The illustration appears to me to be Antirrhinum sempervirens true, quite a distinct plant from the former, which is a pale yellow in colour, the latter being white.—B. CRISP.

Romneya trichocalyx.—My plants of Romneya Coulteri, over 6 feet high, which have given us a fine bloom for years, are poor and shrivelled up this year, with no bloom in the last days of July, whereas the above-named was full of finely-formed flowers at the same date. The plants are about a yard high, but in effect finer than the old kind. They have been fully exposed for several years.

Abelia floribunda in Scotland.—Abelia floribunda, an article on and illustration of which appeared in your issue of July 22nd, grows and flowers well outside here. It is in a rather sheltered position, against the conservatory on a small rockery facing south and looking down on the Gareloch and Firth of Clyde. Various other supposed tender shrubs do well here.—JAMES MACKENZIE, *The Gardens, Glenoran, Helensburgh.*

Single-flowered Hollyhocks.—In some of the gardens in Bournemouth the soil is almost pure sand. I mention this because it is surprising that such stately specimens of Hollyhocks as I recently saw should grow in such soil. I always thought it was necessary to have really good, rich soil to grow plants similar to those I now refer to. Of course, light, sandy ground can be enriched with manure, but this had not been so treated. The plants were growing in irregular clumps, which added considerably to their beauty. The highest were nearly 12 feet; unstacked, but quite erect. It may be that I am specially foud of these plants, but I

think more of them should be grown in our gardens than is the case at the present time.—G. G. B.

The Willow Herb (*Epilobium angustifolium*).—Seeing this, with much pleasure, in various positions in wood and pleasure garden, I thought how little is made of so fine a plant. Under trees and in half-shady positions its beauty was remarkable, the flower-spikes, each a foot long, lasting longer than in sunny positions. The white form is a good plant, too, not so free as the usual one. Neither should ever be allowed in the flower borders, becoming in free soils weeds not easy to get rid of.—W.

Geranium Traversi.—With me *Geranium Traversi* has always grown a little bigger than *G. argenteum* or *G. cinereum*, but I can hardly agree with L. J. Rogers (page 388) in considering the pink flowers "rather disappointing." The white variety is still prettier in my estimation. Much of the charm of *G. Traversi* lies in the silky stems and leaves. I have not found *G. Traversi* as hardy as either *G. argenteum* or *G. cinereum*, as it appears to suffer more from wet winters than either of these.—S. ARNOTT.

Rose British Queen.—This, sent out in 1912, is bearing some magnificent flowers. It is true that while Mrs. Andrew Carnegie has risen in the Rose audit, *British Queen* has gone down from twenty-four to forty-seven, but the former does not flower so freely with me as *British Queen*. The creamy-white flowers of *British Queen* are very fine. It has not been long enough in general cultivation to have found its way into the bulk of gardens, having been introduced by the raisers, Messrs. McGredy and Son, in 1912.—SOUTH SCOTLAND.

The Valerian.—While reading the interesting note on this plant by "Pte. E. M." in the issue of July 29th (p. 368) I was reminded of the grand display it made in a long border close to the grand old Priory Church at Christchurch, Hants, when I saw it recently. The background is formed by an old grey stone wall whereon many kinds of plants nestle in clumps. The position, facing due south, is, naturally, a warm one and the rooting medium very dry. But the plants attain a height of nearly 3 feet and flower profusely. I can well realise how beautiful they look in the quarry referred to in the note mentioned above.—BOURNE VALE.

A good yellow Carnation.—Last autumn I noticed in *GARDENING ILLUSTRATED* a query asking for the name of a good yellow border Carnation. The answer was that there was not such a thing. I am sending you a box of blooms of one I have grown now for some years, and should like your opinion of it. It has a splendid habit and never splits. I fear the layering season will be very late, as my plants are only now coming into bloom, these being the first I have cut.—B. M. HORNER, *Bures, Suffolk*.

[A very good pure yellow, and if the constitution is good in all soils it might be valuable. Soils have a great influence.—Ed.]

A hybrid Primula.—I am much interested in your note *re* hybrid *Primula* in your issue of July 29th, p. 374. I have raised exactly the same thing; colour, a soft apricot flushed with scarlet. The colour varies. Mine are seeding freely, and I hope to ripen the seed. The plants are much taller than *P. Bulleyana* or *P. japonica*, at least with me. I measured my finest spike and find it 46 inches with seven whorls. Several plants have stems over 36 inches. I thought it might be a cross between *P. Cockburniana* and *P.*

pulverulenta. Do you think it would do in the water garden? *P. pulverulenta* does splendidly; also *P. japonica*. My garden is often under water in the winter, sometimes for three weeks at a time, but the plants seem to thrive.—B. M. II., *Bures, Suffolk*.

Cytisus hirsutus.—This upright-growing Broom flowered well during June and the greater part of July, and is now thickly set with its seed-pods, giving a plentiful promise of seedlings should they be desired. The under-sides of the leaves are thickly covered with villous hairs, the young branches having the same covering in plenty. The yellow flowers are borne in the axils of the upper portion of the branches and are freely produced. It is hardy with me here.—DUMFRIES.

Lilium Martagon Cattaniæ.—The *Martagon* Lilies are generally satisfactory in the garden, and the variety *dalmaticum* is so distinct that Mr. A. Grove approves of Mr. Elwes's recognition of it as a separate species. Its deep wine-coloured flowers are very striking. The variety *Cattaniæ*, variously spelled *Catani* and *Cattaniæ*, is, as Mr. Grove says in his work on "Lilies," "a very satisfactory form of the above." The flowers are lighter, but the colour, as the writer already quoted remarks, is "rather difficult to describe." I have grown this variety for well-nigh twenty years, I think, and it has generally given me much pleasure.—S. ARNOTT.

Varieties of the Field Poppy (*Papaver Rhœas*).—I am not by any means acquainted with all the varieties of flowers in this world, but if there is anything to surpass the *Field Poppy* in its now many colour varieties it must, indeed, be very beautiful. The great charm of this flower is its infinite variety allied to its airy gracefulness, and though the flowers do not last very long they are so plentifully produced that one can ignore this. They are truly fairy flowers. I have this year had some seed of an improved strain, and it certainly has produced very superior flowers. Nature appears to be inexhaustible in its power of excelling all its previous best things, and the gardener need never sit down and cry because there are no fresh worlds to conquer, not only in flowers, but in fruit and vegetables; also I believe that our best of to-day will be utterly eclipsed by the products of the future.—W. J. FARMER.

[All these forms are varieties of the *Field Poppy*, and that name should be kept as the right one.—Ed.]

Plagianthus Lyalli.—The beauty of this New Zealand shrub during July cannot be well known, otherwise it would be more often seen. In the neighbourhood of London it has stood for many years in the open, very severe winters killing it to the ground-line, but leaving the rootstock alive to produce new branches. This has occurred twice in the last twenty-five years, but very severe weather might, of course, result in more frequent disaster. Here it grows about 10 feet high, forming a well-branched, spreading bush, but in New Zealand it is said to form a small tree 25 feet to 30 feet high. From the axils of the leaves the clusters of white, pendent blossoms are produced. *P. Lyalli* should be given well-drained loamy soil containing a little leaf-mould, and it is advisable to provide a fairly sunny position sheltered from cold winds. The flowers are borne on the current season's growth, and there is no reason for regular pruning. Cuttings can be rooted in summer, though they are rather difficult to deal with, and better results may often be obtained by layering the lower branches.—D.

TREES AND SHRUBS.

SOME FRAGRANT SHRUBS.

WE might with advantage pay more attention to the many and varied fragrant shrubs, for nothing is more delightful when strolling round a garden than to be regaled with the odours which pervade the air where sweet-smelling plants are grown in quantity.

Upon the turf or in the "wilderness," by stream or woodland walk, we might have fragrant shrubs in masses, and they would pour out odours as rich and variable as the subjects which emit them. The *Lavender* is one of the sweetest of dwarf hardy shrubs, but hardly anyone thinks of planting it when making a shrubbery. It is beautiful when in bloom, as everyone knows, but so it is when out of flower, as the eye finds repose in, and never tires of looking upon, its soft-cushioned masses of silver-grey foliage. This is one of the things that might be boldly used in the foreground of the shrubbery between the taller shrubs and the turf; and, moreover, planting shrubbery margins with such things as these would render digging unnecessary. Another sweet thing of the same grey colour is the *Lavender Cotton* (*Santolina*). It has yellow Daisy-like flowers in summer. Then there is the *Rosemary*, which no garden should be without. It always looks fresh in its dark green dress of richly-scented leaves. Probably these three things are the most accommodating of all the scented shrubs, for they will flourish upon hot, dry, stony soils where little else would grow. Equally as sweet and hardy are the different forms of the *Southernwood* (*Artemisia*); in fact, this is quite a large genus, of which it is rare to see a single member in gardens. *Comptonia asplenifolia* is a hardy, spreading, bushy shrub with elegant Fern-like foliage, which gives off a delightful odour when touched. It is called the *Fern-leaved Gale*. Then there is the *Bog Myrtle* or *Sweet Gale* (*Myrica*), so suitable for wet situations. Many of the herbs might be used, especially such things as *Marroram*, *Camomile*, etc. The *Sweet Bay* is one of the finest of scented shrubs, and a valuable Evergreen too. Upon warm soils it forms quite a tree as much as 40 feet high. The *Sweet Verbena* (*Aloysia citriodora*) has a perfume which all appreciate. It is one of the most useful scented shrubs for cutting. Although considered and usually treated as a greenhouse plant, it will live out of doors in many southern gardens, especially if planted against a warm wall. Even raised from cuttings in spring and planted out in May it rapidly grows into a bush, with plenty of young shoots for cutting. It strikes very easily.

The *Balm of Gilead* (*Cedronella triphylla*) has a delightful odour. It is a half-hardy shrub in most situations, but would probably prove hardy in favoured spots in the west and south of England. It forms a spreading bush about 4 feet high, and the shoots are terminated by a little spike of pale flowers, but they are dull and ineffective. The merit of the plant is its fragrance, and as it can be readily struck from cuttings and grows freely upon warm soils it should be treated as half-hardy, and young stock be raised and planted out every year. *Junipers* and *Escallonia macrantha* have also a nice fragrance, whilst in the *Rose* family there is a variety of delicate odours in the leaves as well as the flowers, the best known and most appreciated being the *Sweet Brier*, which should be found in every garden.

THE LEPTOSPERMUMS.

THE most interesting shrubs at the recent exhibition at Holland House were the species and varieties of *Leptospermum*, several of which had red flowers. Until recent years the principal *Leptospermums* in cultivation had white or cream flowers, and a good deal of attention was paid to a group of a red-flowered kind which was exhibited for the first time at the International Exhibition at Chelsea in 1912. Since that time, apparently rapid strides have been made in the production of bright-coloured sorts. The family includes a score or more species, all evergreen shrubs from New Zealand and Australia, but of that number a few only are grown in the British Isles, and the outdoor cul-

the dried leaves as a substitute for Tea. In some parts of Australia and New Zealand the commoner kinds sometimes become a nuisance, for, after an area of land has been burned over, or otherwise cleared, one or more *Leptospermums* spring up in thousands and exclude to a great extent other vegetation, a densely-covered area being as difficult of access as a well-grown plantation of the Common Gorse here.

In the warmer parts of the country the *Leptospermums* can be planted as other shrubs in ordinary good loamy soil, the addition of a little peat or leaf-mould at planting time being an advantage. Except for the purpose of shaping the bushes in a young state, pruning is not required, and

more favourable places. The leaves are small and sharp-pointed, and the white flowers are barely $\frac{1}{2}$ inch across. One of the first of the rich-coloured sorts to claim attention was

L. CHAPMANI, said by some people to be a sport from *L. scoparium*. It has rose-coloured flowers, the colour of seedlings varying from bright rose to white, and its leaves from green to purple. The plant, however, to arrest attention here was

L. SCOPARIUM NICHOLLSI, or *Nicholli* as it is more frequently spelled. This, according to the "Botanical Magazine," t. 8419, was brought from New Zealand by Captain A. A. Dorrien-Smith in 1908. It was originally found on the sandhills to the north of Christchurch, and is thought

Part of a flowering shoot of *Leptospermum ericoides*. Nymans.

ture of those is restricted, for they are only really hardy in the milder parts, though there are other places where they succeed against walls, and they are well worth growing as cool or cold greenhouse plants either in pots or in tubs. Although they are only known as bushes here, some species form goodly-sized trees in New Zealand and Australia, reaching a maximum height of 40 feet to 60 feet with a diameter of 2 feet to 3 feet. The timber of such trees is valuable, and according to "Kirk," "Forest Flora of New Zealand," it is strong, durable, tough, and elastic, and is used for house-bloeks, piles, marine jetties, fences, spokes, etc., the smaller wood being used for Hop-poles and other purposes. Many of the species are known under the common name of Tea Tree, from the fact, it is said, of early settlers using

it is possible to add to the stock by inserting cuttings of half-ripe shoots firmly in sandy soil in a close propagating frame during summer. When grown in pots the plants should not be over-potted, but kept in health by feeding, and they should be stood out-of-doors in full sun during the summer months. A point to remember in the cultivation of pot or tub plants is the fact that they must not be allowed to become very dry, for once they suffer from drought it is difficult to get them to regain their vigour. At the same time they must not be allowed to become water-logged or they will suffer to an equal extent.

L. SCOPARIUM, the Manuka or Tea Tree, is one of the best-known species. In New Zealand it varies from a prostrate shrub on the mountains to a tree up to 30 feet high, with a trunk 2 feet in diameter in

to have originated as a seedling from a white-flowered plant. It is said to grow from 10 feet to 18 feet high, and is attractive by reason of its purplish leaves and its freely-produced deep-red flowers, which are each about $\frac{3}{4}$ inch across. Another equally beautiful plant is

L. BOSCAWENI, which has purple leaves and large red flowers. Hybrids between *L. Boscaweni* and *L. Nicholli* were on view at Holland House, the colour of the flowers varying from pink to dark red. One of the most beautiful was called Donard Beauty, whose petals were deep pink with a dark-red blotch at the base of each. This was given an Award of Merit. Another called Radiance, with red flowers, was equally good. The flowers in each case were about $\frac{3}{4}$ inch across. They were exhibited by the Donard

Nursery Co., Newcastle, Co. Down. The accompanying illustration gives an idea of the freedom of flowering of *L. Boscaweni*.

L. ERICOIDES is naturally a larger-growing species than *L. scoparium*, and the larger trees in New Zealand are said to be between 40 feet and 60 feet high. It also is called Tea Tree, and in New Zealand it is given the native name of Manuka-rauriki. The leaves are very small and the flowers white. An idea of its free-flowering qualities can be gathered by the accompanying illustration. It is very common in some parts of New Zealand and Australia, and in addition to other uses the wood is employed largely by settlers for heating.

L. LANIGERUM is widely distributed in some parts of Australia and is sometimes grown here, though it is generally less useful than those already named. Here it does not bloom very freely and is less worthy of general cultivation.

L. FLAVESCENS, also from Australia, grows from 15 feet to 20 feet high and bears small yellowish flowers.

L. GRANDIFLORUM greatly resembles *L. scoparium*, but is very free-flowering and the flowers are of large size.

Although other kinds have been introduced, it is probable that those already mentioned are of more value than the others, and are, at any rate, more easily obtained. D.

NOTES AND REPLIES.

New flowering shrubs.—At the Holland Park Show of the Royal Horticultural Society Awards of Merit were made to two pretty and very promising flowering shrubs, both of them of garden origin. *Escallonia Donard* Seedling was raised from *E. Philippiana* crossed with *E. langleyensis*. As this latter had *E. Philippiana* as one of its parents there is, of course, a considerable amount of *E. Philippiana* influence to be found in the new-comer. The flowers of *E. Donard* Seedling are freely borne and of a pleasing blush tint, the habit of the plant promising to be fairly compact. The second Award of Merit was given to *Leptospermum Donard Beauty*, described as the result of a cross between *Leptospermum Boscaweni* and *L. Nicholli*. Of these two *L. Nicholli* attracted a large share of attention at the International Exhibition in 1912, when it was awarded the silver cup as the best new plant in the show. The flowers of this are of a rich ruby-red. The variety *L. Boscaweni* was also shown at the same time, and received an Award of Merit. This is of looser habit than *L. Nicholli*, with larger flowers, which are nearly white, with a red centre, the buds being red. The variety *Donard Beauty* has the large flowers of *Boscaweni*, their colour being bright rose and of a somewhat paler tint at the edges. Both were shown by the Donard Nursery Company, Newcastle, County Down, Ireland.

The present season.—Among gardeners the present season seems likely to be branded as notorious for weeds and insect pests. No doubt both, especially weeds, have been more difficult than usual to deal with, but a little thought would show that the season is not altogether at fault. Most of us are suffering from the want of labour, and even in cases where men can be got they are unskilled, and have not the same interest in the work which is displayed by young and keen gardeners. With the lack of attention and the shortness of hands it is little wonder if weeds and pests are more in evidence than usual, but I am not prepared to admit that the increase of these worries is altogether due to the season.—W. McG., *Balmae*.

FRUIT.

STRAWBERRY INTERNATIONAL.

OF Messrs. Laxton's introductions of recent years, this stands out in my trials as a great advance. Of its value as a field variety I have no experience, but if one may judge from the vigour of the plant it should be a good market sort. The fruits, large and very bright, make an imposing dish. I do not say that it has come to replace Royal Sovereign, because it has not the same freedom and continuity, but, nevertheless, it is a noble Strawberry. It is strange that so many Strawberries do well for a time and then fail. One can recount numberless sorts, novelties of passing years, that in their youthful days were all or almost all one could desire as regards cropping and vigorous growth. After a brief life some of these sorts seem to, as it were, turn back and refuse to crop. Whether International will follow in the wake of its many predecessors time alone can decide. At the present time, at any rate, it inspires one with hope of maintaining its good name.

I am so favourably impressed with the general merits of International that I intend to extend its culture at the expense of others which, though giving very good crops of attractive fruits, fall behind in the averages. I have always favoured trials of new introductions, and learned much from these. At the present time I have a goodly number established, and with which I am able to make comparison. I discard only when it is found by more than one season's trial that the newcomers are not profitable. The bright colour, size, shape, and stout leathery leaves of International combine to make it a conspicuous as well as a favourite Strawberry. There are, I know, many who pin their faith to Royal Sovereign, but good as this is everywhere, I feel sure the palate would yearn for a change. It is only from young plantations that a really good stock of runners can be had. Planted during August most varieties will give a fair crop of fine berries in the season following, but it cannot be expected unless the runners are taken from young beds that have not been weakened by heavy cropping.

W. STRUGNELL.

MELONS IN FRAMES.

I SHOULD be obliged for hints as to Melons in frame. We have Sutton's Blenheim Orange, No. 1, but never succeed in growing them larger than 1½ lb. to 2 lb. We never have more than three on one plant. My gardener thinks it has something to do with soil.—LITTLE CHANG.

[Many amateurs would like to grow a few Melons, but are deterred by reason of the idea being prevalent that a hot-water apparatus of some kind is absolutely necessary. This is certainly not the case, unless the owner desires fruit early, for excellent crops can be produced in pits or frames by means of a little bottom-heat to give them a start, after which solar heat will be enough to keep them going. The main thing to ensure success is not to start too early in the season, for although we sometimes get very warm weather in April we almost invariably get a spell of cold again in the early part of May, and those who have not got pipes at command should not plant out their Melons until they are certain that they can keep them going without any check. As the pits and frames are usually fully occupied up to the beginning of May it is the best plan to sow the seed about the first week in April in the warmest quarter at command, and grow the plants on in pots until the

pits are ready, and as soon as they can be set at liberty have them emptied and thoroughly cleansed, washing the lights and giving the sides a dressing of fresh lime-wash; then put in a good body of fresh stable-manure, trodden in as hard as possible, for the tighter it is put together the slower and more lasting will be the heat. As soon as the heat has well spread through the whole mass put in some turves, with the Grass side downwards, in the centre of each light, and on them put a barrowful of turfy loam that has been stacked up for about three months; this should be chopped up, but not sifted, and as soon as it gets warm the plants may be put out. Some tepid water should be given to settle the soil, and after hot days a good syringing will greatly accelerate growth, but if dull weather prevails, too much moisture must be avoided, especially close up to the main stem of the plants, or they may rot off altogether; in fact, when the fruit is nearly full grown it is the best plan to keep the soil around the stems rather dry and water where the extremity of the roots can find it. When the shoots begin to run out about half-way across the frame the best time for earthing up has arrived, and this should be done with turfy loam, chopped up and trod in very firm; this will grow Melons to perfection without any addition whatever. The leading shoots should then be stopped, when a number of side branches will push out, and on these the male and female flowers will appear. It is advisable to fertilise these. One thing to guard against is to see that one or two fruits do not get too much in advance of the others, for the nearer a good regular crop can be set together the better, as they swell off more evenly. When the fruit gets near to ripening let the soil get rather dry, admit plenty of air, and elevate the fruit on tiles or flower-pots to keep it free from damp.]

GRAPES SCALDED.

I SEND some Grapes grown in my vinery. Please say what is the cause of the rotting? I have nine Vines (various), and may say that before the war I was a successful exhibitor at Shrewsbury with them for many years, but the war took my gardener, and I had to rely on an old-age pensioner, who has been an excellent gardener in his day. I have not forced the Vines this season at all. I fancy it is damp that has caused it, and that he would not give sufficient air. I have had to cut many berries out, but many bunches are not affected.—WREKIN.

[The berries you send have been what is known as "scalded." This always occurs during the stoning period, and is most troublesome in stormy and changeable weather, when, no matter how careful the inside management, the air temperature rushes to extremes. Under these rapid fluctuations the economist who grudges fuel allows the night temperature of the house to fall to a low figure, when the berries long before daybreak become extremely cold. A bright, sunny morning breaks, the temperature of the house rises faster than that of the berries, condensation of vapour follows, and a portion of the skin is destroyed.

Scalding does not extend over a long period—generally from a fortnight to three weeks, more or less, according to the regularity of the "set" and the active condition of the roots, while the greatest destruction almost invariably is experienced where ventilation is imperfect and the borders are wet and cold. The amateur who never reads his calendar, when he finds his berries scalding, unmindful of the fact that this subject has been discussed over and over again, at once sends berries to the editor of his paper, but be-

fore the oft-repeated reply can reach him the mischief is done, and many of his best bunches are disfigured, if not spoiled. Once more, then, upon the principle that prevention is better than cure, we would suggest the production and maintenance of conditions the reverse of those described. The fires, in the first place, should be started sufficiently early in the afternoon not only to expel sluggish vapour, but also to maintain a brisk circulation of warm air through the night. The apex ventilators should never be closed, and, the better to prevent a sudden rise, fire-heat should be shut off before the sun strikes the roof, when, by abundant, if not profuse, ventilation, a warm greenhouse temperature may be maintained through the day. Cold

crowding. Some varieties need but little pruning, owing to their habit of growth. For example, established trees of Kirke's, Reine Claude de Bavay, and Coe's Golden Drop very rarely produce such a superfluity of shoots as is the case with Washington, Victoria, Brahy's Gage, and others of more robust growth. A good watering is afforded to each tree as the pruning is done, as this has been found to give the young fruits a fillip. Blister, which for some time had been troublesome on Nectarines out of doors, has now disappeared under the influence of the warmer nights. Both these trees and Peaches are fairly well cropped, and at present the fruits are stoning. To assist them over this stage waterings are being

VEGETABLES.

SPINACH FOR WINTER AND SPRING.

WHERE Spinach is in demand throughout the winter and spring the value of a good breadth of it is great. In very many instances Winter Spinach is often very unsatisfactory. The grub of the Spinach moth is for the most part answerable for these failures, which are more prevalent in some seasons than others. The best preventive is to have the ground fallow at least a month before sowing, during this time well forking it over, thus exposing it to birds and the pulverising influence of the atmosphere. With soil nicely fined down the seeds germinate much more kindly. With Winter Spinach there is generally a difference of opinion as to the date of sowing for the main winter crop. The danger is, that if sown too early and the autumn should turn out warm and dry, it may run to seed, and if sown too late there is not sufficient time for it to become large enough to be of use for gathering during the winter. A week or two often makes all the difference one way or the other. For late districts the first week in August is none too early, but for earlier and warmer parts the end of the second week or throughout the third week is the more suitable. It is a good plan to make two sowings, one during the early part of the month and the other at the time stated. In this case the earlier sowing may be gathered from in the autumn, the other not being gathered from upon any account until the winter. The chances are if the winter crop should be gathered from in the autumn the growth will be checked. This may appear a simple matter, but it is best to be prepared if Spinach is expected to be forthcoming at all seasons, or, at any rate, when the weather will allow of its being gathered. Another sowing should be made at the latter part of September. This commences to turn in just as the winter crop is going over. It is well known how quickly the winter crop runs to flower upon the return to sunny and more genial weather. With the sowing under notice, the seedlings grow but very little before hard weather sets in, but at the turn of the day they commence to start nicely into growth and bear long before any sown in the new year.

For the main breadth of Winter Spinach there is nothing like having the plot in an open position, as here the plants are not likely to be attacked by grubs. Spinach follows well after Potatoes or even Peas. The soil having been well forked over, should, previous to having the surface broken down, receive a fair dressing of soot and also burnt refuse. This, besides stimulating growth, also has a deterrent effect upon grubs. For providing the supply for the winter season the Prickly-seeded is the variety generally grown, but Victoria is now having many advocates, it being considered much superior on account of the larger leaves and not bolting so quickly in the spring. Whatever merits Victoria may have, the older Prickly-seeded will continue to be largely grown, as on suitable soils the leaves of this even will grow surprisingly large. The drills should be drawn quite 18 inches apart, as crowded rows are not very desirable, the seeds also being sown thinly, as if at all crowded the young plants become unduly disturbed in the thinning, which should be gradual, or an attack of grub may lessen the number of plants. Although Winter Spinach likes a moderately firm soil, yet surface hoeing is very essential, this promoting a healthy and free growth, and,

Part of a flowering shoot of *Leptospermum Boscaweni*. Nymans. (See page 397.)

draughts must be guarded against, otherwise another enemy in the form of rust may put in an appearance, when the intended remedy may prove worse than the imaginary disease.]

NOTES AND REPLIES.

Summer pruning is being attended to now, Plums being dealt with. In a general way Plums are much too severely handled. Neat trees are all very well, but when neatness can only be achieved by the extravagant use of the knife it may be assumed that a tree so treated will either have a short life, be troubled with gumming, or shy in fruiting. It is better to prune as sparingly as possible, and to lay in as much young wood as can be found room for, avoiding, of course, over-

given from time to time as occasion requires.—KIRK.

Nectarine Cardinal.—This Nectarine, sent out by Messrs. Rivers in the autumn of 1896, has well maintained the position which it immediately claimed. In Cardinal all the good qualities which one looks for in a Nectarine are combined—size, colour, appearance, flavour, and freedom of setting. An additional recommendation is its earliness, the variety being quite a fortnight in advance of Early Rivers. Cardinal, unfortunately, does not succeed out of doors, but does well in quite a cool house. Cardinal is a clingstone, a fact which detracts from its value with some, but intending planters during the coming autumn might, with advantage, give it a place.

besides, if grubs should be present this will disturb them; in fact, hoeing should be practised as long as possible. In gathering, a leaf or so should be taken off each plant, as then the plants are more likely to keep on giving a supply, weather permitting.

NOTES AND REPLIES.

Grubs at roots of Cauliflowers, etc.—I send some grubs which are attacking my winter Greens, in particular Cauliflower and Broccoli. I have pulled up thirty to forty. Can you tell me what to do with remaining plants, as I am afraid they will be attacked as well?—A. W. ARNOLD.

[The grubs attacking your plants are the larvae of the Cabbage-root fly. They are very troublesome, but, as a rule, their attacks do not continue much later than this. The best preventive measure is to sprinkle sand moistened, with paraffin along the rows in order to check the flies from laying their eggs. It is too late to hope for much from this measure. Watering the rows with a weak solution of carbolic acid is said sometimes to give relief, but this must be done with caution, so that none of the fluid touches the foliage.]

Cabbage.—Where a large and continuous demand for vegetables has to be met, a good breadth of these should be planted at once for autumn cutting. A good variety for household or general purposes is Enfield Market, which grows to a good size and is of excellent table quality. The plants should be set out not less than 18 inches apart each way. For dining-room and similar purposes Rosette Colewort should still be planted in quantity on any piece of ground that may be available. These, as has before been mentioned, may be set out 1 foot apart each way. The hardy winter varieties should be allowed a distance of 18 inches both between and in the rows.

Broccoli.—Advantage should be taken of the moist condition of the soil to get the various breadths of Broccoli planted. The varieties will, or should, consist of such as will form a regular succession from late autumn until June in next year. For the first-named purpose Autumn Protecting is very reliable, and can always be depended on to produce medium-sized heads of the highest quality. To succeed the foregoing there are Winter Mammoth and Christmas White. After this Spring White and Vanguard will yield good, useful-sized curds. Then come the main crop varieties, of which there are many valuable kinds, and finally the late sorts, such as Model, Late Queen, and others. Planting should be done on firm ground, otherwise soft growth and stems will result, which quickly succumb when subjected to severe and prolonged frost. If space is available for so doing, the plants should be set out 2 feet apart both in and between the rows.

Late Peas sown the second week in June have been earthed up and the sticks placed in position. New sticks were chosen for this crop in order to withstand the rough autumn winds. If dry weather sets in a good mulching of dung will be applied before the ground becomes very dry, in order to avoid having to give cold water to the roots, which is a fertile source of mildew.

Leeks.—The plants for maincrop supply are now of a sufficient size to transplant. These are grown in trenches taken out in the same way as for Celery. The plants will stand 9 inches apart in the rows, and the latter 1 foot asunder in the trenches.

Herbs.—The various kinds of herbs are now coming into flower. A sufficient quantity of each should, therefore, be cut when dry, tied into bunches, and suspended under the roof of an open shed to become dried for winter use.

GARDEN FOOD.

THE ARTICHOKE.

This vegetable is now in season, and very welcome it is. There are various ways of cooking it in France, but it is not easy to beat plain boiling. It should not be served hot, but cooked beforehand and served cold with a little oil and Lemon-juice by way of sauce, and that is not wanted by those who like the Artichoke plain. Old, neglected plants give poor heads. Plantations should be renewed now and then and the shoots of old plants thinned out in spring to one or two. It is needless to use any second term for this plant, the only true Artichoke. The Sunflower we dig up the roots of in winter is a very different thing, and a good thing, too, in its season. There is endless confusion in the cookery books, owing to the names being misapplied. The French never make this mistake. We give a few French recipes from *L'Art du bien manger*:—

ARTICHAUX A LA PROVENCAL.—Prenez des artichauts que vous nettoyez dessus et dessous; faites-les cuire un quart d'heure dans l'eau; ôtez-en le foin: mettez-les sur une tourtière avec huile, gousses d'ail, sel, poivre; faites cuire feu dessus et dessous: quand ils sont cuits, ôtez les gousses d'ail, et servez avec un jus de citron.

ARTICHAUX SAUTES.—Coupez en quatre des artichauts moyens et tendres, ôtez le foin et parez-les en leur laissant à chacun trois feuilles; lavez et essuyez. Mettez du beurre dans une casserole où vous arrangerez vos artichauts, et les mettez sur un feu doux seulement vingt minutes avant de servir. Dressez-les, sur le plat, en turban. Mettez une cuillerée de chapelure dans le beurre, autant de persil haché et un jus de citron, un peu de sel: servez cette sauce dans le milieu des artichauts. Il ne faut pas les blanchir.

ARTICHAUX AU GRAS.—Coupez en deux de moyens artichauts, ôtez-en le foin et les parez: faites-les blanchir à l'eau et sel; lorsqu'ils sont cuits, mettez des tranches de lard gras dans une casserole, avec une ou deux tranches de veau, deux oignons, une carotte, un clou de girofle et très peu de thym; arrangez les artichauts sur les hardes et le veau, et mettez sur un feu doux. Quand le veau a pris couleur, mouillez avec un peu de jus ou du bon bouillon: faites mijoter. Servez les artichauts en turban, et la sauce que vous avez liée de fécula, au milieu.—(*Ancienne mode.*)

ARTICHAUX FRITS.—Prenez-les, petits et très tendres, les couper par quartiers, et les faire blanchir à l'eau bouillante salée. Faites une sauce à la poulette, composée d'un morceau de beurre fondu à la casserole; ajoutez une cuillerée de farine, mouillez de crème, liez de jaunes d'œufs; trempez-y les artichauts, laissez-les refroidir. Au moment de servir, trempez-les dans une pâte à frire.

ARTICHAUX A LA DISLAIRE.—Après avoir ôté le vert de dessous, coupez les feuilles de dessus à moitié, ou les partagez en deux. Le foin ôté, blanchissez à l'eau bouillante; faites-les cuire avec du bouillon, du sel, poivre, un houquet de persil, ciboules, deux clous de girofle, un oignon, une carotte et la moitié d'un panais. Presque cuits, égouttez-les, et les farinez pour les faire frire; servez-les garnis de persil frit.—(*Mode ancienne.*)

A good part of the Artichoke is the base or bottom, called by the French *Fond d'Artichaut*, which is used largely in winter cookery, preserved. It is very good indeed for winter use. Best of all, though, is the bottom of the Artichoke in summer when freshly cooked. The "fond" is easily taken away from the head, and the scale of good heads is used at the same time. As the plant is a very free bearer when well grown there are often more heads than one can use, and it is then a very good thing to save them all for winter use. Treated well in the garden and kitchen the Artichoke affords one of the most wholesome and delicate of the mid-

summer foods. There are several varieties in cultivation in France, and any one with experience of these would confer a favour by telling which of them is found the best for our country.

HOT SALADS!

Vegetables should always be hot when made into a salad, for they absorb the dressing as they cool. Such ingredients as Potatoes, Haricot Beans, Lentils, Rice, in fact all starchy foods should be finished by adding stock, milk, cream, or mayonnaise sauce when they are made into salads, as this treatment gives them a creamy consistency. They are too often served dry and unappetising.

The above, from the *Telegraph*, is among the amusing items of news one may gather since the great dailies took to writing on gardening and cookery. We should say the sort of salad so made is a salad to be avoided. Coolness, freshness, well-grown Lettuce, and no mixture of meaty stuffs of any sort are what should be sought in a British garden salad.

NOTES AND REPLIES.

Mountain Ash Berry jelly.—I should be greatly obliged if you would say if fruit of Mountain Ash enclosed is edible. I am told it can be made into preserve.—E. E. L. CAIGER.

[Yes, the berries can be made into jelly. The berries must be gathered when dry and quite ripe. Pick off the stalks and put into a preserving pan with a little water, and simmer until they can be broken up. Pour into a jelly-bag and run the juice through, but do not use any pressure or it will not be clear. Allow a pound of loaf-sugar to every pint of juice. Boil rather rapidly for an hour, skimming well, then put into perfectly dry pots and tie down at once. The berries you send are those of the yellow-fruited form, the ones generally used for the making of jelly being those of the red-fruited variety.]

Apple jelly.—In this district, and in others, too, the Apples are falling in large numbers as a consequence of the cold, inclement season, and it is specially important this year that they should not be wasted. Many people do not know that immature Apples make delicious Apple jelly—much nicer, in fact, than ripe Apples do—and the process is quite simple. Here is a good recipe:—Wash the Apples thoroughly and put them into a preserving-pan with just enough cold water to cover them. Let them boil for about an hour until they are reduced to a pulp, and then strain the juice through a stout muslin bag. Add to the juice preserving sugar, allowing 1 lb. of sugar to every pint of juice, and then boil gently for 2 or 2½ hours. A little Lemon-juice added is thought an improvement by many. It will be found that a pint of juice with 1 lb. of sugar will make 1½ lbs. of jelly, and with sugar at 6d. a lb. the cost will work out at 4d. per lb. of jelly, exclusive of firing, so it is quite a cheap preserve, and goes further than jam, and being, of course, free from pips or stones, is especially good for children.—N. L.

Cucumber fritters.—If Cucumbers are plentiful they will make an acceptable change when cooked in fritters. Peel the Cucumber, cut into slices ¼ inch thick. Make a batter with one well-beaten egg, half a cup of milk, and enough flour to make it of the right consistency to drop from spoon. Season batter with salt and pepper. Dip each slice of Cucumber in the batter, coating it well, then fry a nice brown, and serve very hot.

PLANTS AND FLOWERS.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

CRANESBILL IN THE ROCK GARDEN.

It is doubtful if we make as good use of these plants as we well might. They have the great merit of hardiness with good colour. Some of them have much beauty, as the one figured here, and which is very useful in the rock garden. The Spanish and English Geraniums take to the Grass, and look very pretty among it. The Spanish *G. ibericum* kind is most vigorous, and fights its way in a hedgerow, and the white form of our native kind is also

against the grey stone of the retaining wall on which it grows. There is now a number of plants at Monreith, and although it does not give spikes up to 4 feet in length, as is said to be the case in some places, they are very handsome.—S. ARNOTT.

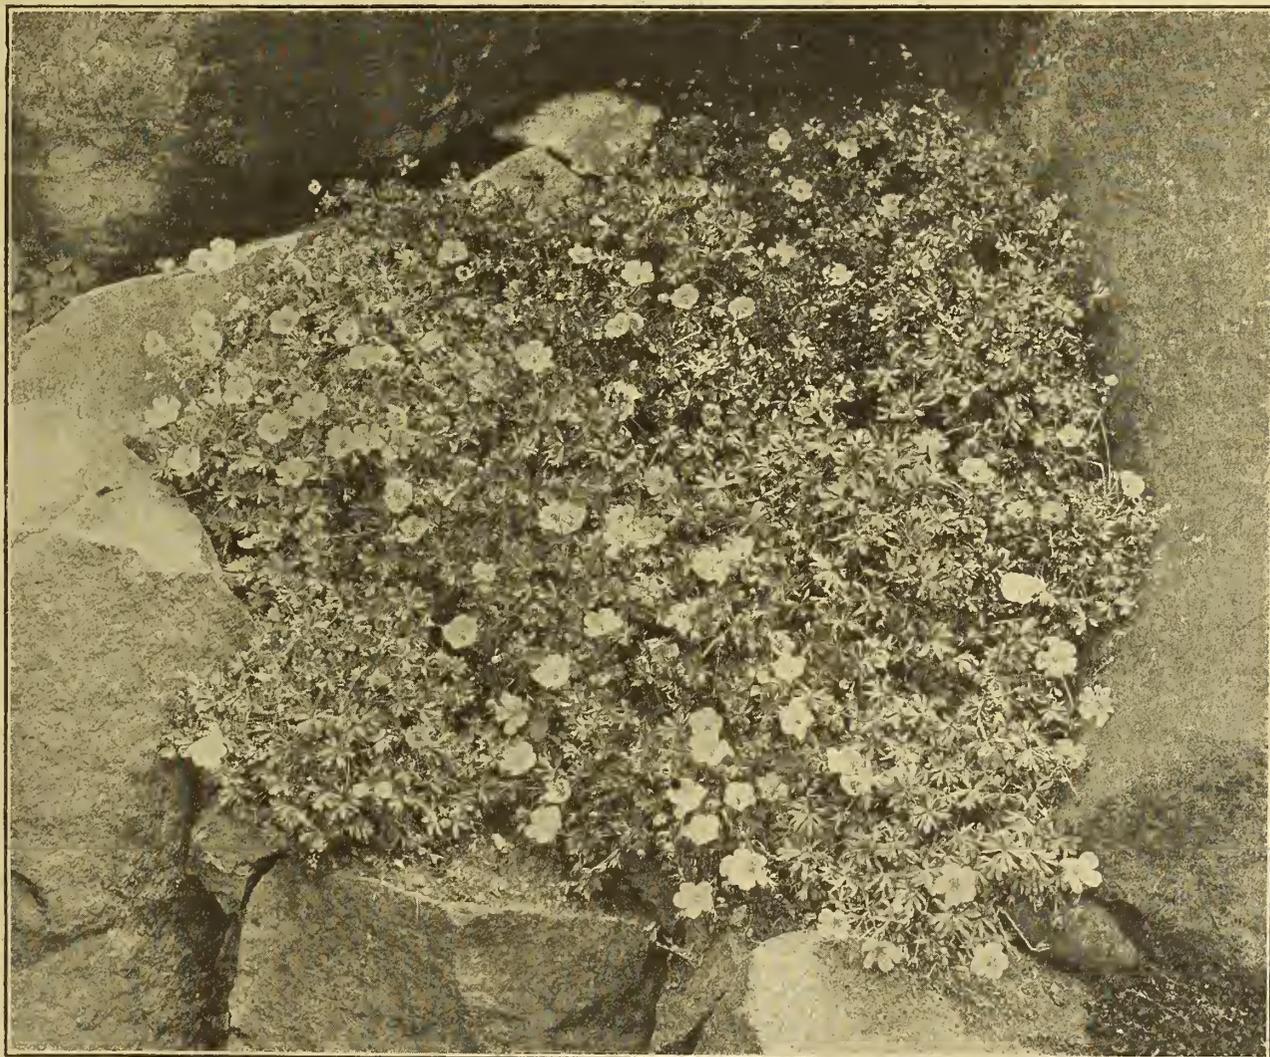

Campanula rotundifolia alba.—Several forms of the white variety of *Campanula rotundifolia* are in existence, some of which are not only purer but have larger flowers than others. I have a good white one, which I received a good many years ago from Mr. T. O. Walker, of Carnforth. This produces sheaves of good, open, pure-white flowers every year.—S. ARNOTT.

Æthionema Warley Hybrid.—I am very fond of all the *Æthionemas*, the flowers are so delicate and pretty, and the foliage is usu-

OUTDOOR PLANTS.

PROPAGATING BEDDING PLANTS.

The propagation of Zonal Pelargoniums should commence by the middle of August, and wherever possible every cutting should be inserted by the end of that month. Many, especially trade growers, strike them in "stores," that is, something less than a dozen in a 6-inch pot, and pot them off in early spring. It is perhaps the most economical way of wintering them, as so many can be stored away in a small space, but it necessitates a lot of labour at a time when there is much work coming on, and at the present time, as all interested in gardening work know, labour is scarce and expen-

The Silvery Cranesbill (Geranium argenteum) at Friar Park.

very effective. The one we show is an extremely good example of an arrangement which cuts it off from various enemies, and looks very effective. The Armenian Geranium is a very showy plant. Some people object to the colour. I do not. There are some not yet in cultivation that are well worth attention. W.

NOTES AND REPLIES.

Saxifraga Cotyledon icelandica.—In this we have the finest of the forms of *Saxifraga Cotyledon*. It appears, however, that *icelandica* is a misnomer. It is said to grow well at St. John's, Oxford. At Monreith, Sir Herbert Maxwell's garden in Wigtonshire, it is magnificent in the wall garden, the massive, yet elegant, spires of bloom showing well

ally of an attractive glaucous hue and the habit neat. This hybrid has flowers of a much richer shade than most, the colour a bright rose-pink. The flowers are small and the whole plant is compact. Like most of its family, it likes a dry, sunny position in a light soil with a fair proportion of lime. All the *Æthionemas* should be cut back after flowering to keep the growth from becoming straggly.—W. O.

Campanula rotundifolia Hosti.—This, with the form called *C. r. alpina*, not to be confounded with the species *alpina*, should be grown in every garden where rock plants are cherished. It has much larger flowers than those of the typical *C. rotundifolia* (a very variable plant, by the way). The flowers are large, produced in great numbers, and are of a deep purple blue. There are some forms of *C. r. Hosti* which are much better than others.—S. A.

sive. For years past I have struck my Zonals singly in 2-inch and 2½-inch pots, according to the season and condition of the cuttings. They are stood in the open and in fine weather watered once a day, but never in the evening, which minimises the danger of damping. In a time of extreme heat they may need more than this. In this way labour is lessened in spring. The pots are then full of roots, and as soon as growth commences they can be fed so that when they are planted out they have trusses on them as large as those produced by much older plants later in the season. The advantage of this is obvious. The beds are effective early in June, whereas when the cuttings have to be potted off in spring there is a check from which it takes them some time to re-

cover. In blooming power plants grown as above indicated are equal to two plants wintered in stores, and are quite as good as three spring-struck plants, which cannot be relied on to come to their best before the middle of July. I would advise readers to try this way of propagating bedding Zonals. I feel sure that one trial would convince them of its superiority over the method usually followed. It may be objected by some that the pots being full of roots quite early in the year, the plants become to some extent starved, and therefore in a measure deprived of their blooming power, but they can be fed, and all practical men know what can be done in this way when the plant is healthy and the pots filled with active fibres.

VERBENAS are not so much grown as they were. When I was a young man they were considered indispensable, and beds of Brilliant de Vaise, Purple King, and Mrs. Holford (a fine white) were prominent features in well-ordered gardens. From some cause or other, I think possibly to the express method of increase adopted to meet the great demand, the constitution of the popular varieties declined. They fell a victim to some kind of disease, and it was found impossible to make them a part of the flower-garden arrangements. In my early days I had much to do with the propagation of this class of plant, and quite 90 per cent. of the cuttings was struck in warmth in spring. In the course of time this undoubtedly exercised an enfeebling effect. It is, moreover, sometimes difficult to obtain good succulent cuttings from flowering plants. There should be reserve plants which should be in good ground and not allowed to bloom, from which stout growths in plenty can be obtained in August, and which, inserted in 42-pots at the rate of about a dozen to the pot, and wintered in a cool-house, will form sturdy little plants ready for potting off early in April, and which can go into cold frames where, in favourable weather later on, they can be exposed to outside influences. Such plants become very hard by the end of May, and as the Verbena will bear a certain amount of frost without injury they can be planted out at a comparatively early date, and therefore get good root-hold before the hot weather arrives.

CALCEOLARIAS are perhaps the most economical bedding plants in use, as they need no artificial warmth to keep them through the winter. They never do so well as when wintered in old-fashioned turf pits with a light on them. The turves keep out frost much better than bricks, and with some litter on the frame the plants will come through a hard winter without injury. The cuttings are simply inserted in free soil and can then be lifted with good balls. Calceolarias are very impatient of artificial warmth, and never seem to have the vigorous health when struck in pots and wintered in a greenhouse. Many of the failures with this plant are due to late planting. The latter end of May is too late. They should be in place by the beginning of the month, which can be done with safety if wintered as above indicated. I have known plants stand over the winter when not very severe.

PARIS DAISIES can be wintered in the same way. They are not very tender and do not damp off. They could well be wintered in a cold frame with, of course, protection against hard frosts. It is as well to know this, for the amateur and trade grower have never too much room in heated greenhouses during the winter.

HELIOtropES are altogether different. The newer varieties seem to be more tender than those grown some thirty years ago, and if the temperature is frequently

below 45 degs. they are apt to cast their leaves. They should be propagated early in August, putting half-a-dozen cuttings into a 2½-inch pot, as they winter better when the pots are full of roots. Stand them in the warmest end of the greenhouse and be very careful in watering from December till March.

LOBELIAS are often raised in warmth in March, but this is a mistake. Seed should be sown in boxes or pans early in September, allowing the seedlings to remain in a cold frame until December, with full exposure in fine weather. Sturdy, hardy little stuff will be the result, and they can be pricked off early in April, taking them out in little bunches. By the time they are to go into the open air they should be nice compact little plants and well in bloom. It is not everyone who has a warm house for raising seeds early in the year, but all who possess a cool greenhouse can command in the manner above described a good stock of this useful little bedding plant, almost indispensable for window-boxes.

AGERATUMS are nowadays frequently raised from seeds in spring, but they are very easily struck from cuttings, putting a dozen into a 4½-inch pot, and they are not liable to damp off. I do not see, however, why they should not be raised from seeds in July or early in August and wintered in the seed-pans.

PETUNIAS can be propagated from cuttings, but only in early spring, when succulent shoots can be had. Seedlings are preferable, and must be raised in heat. Coleus and Iresine strike easily in August, but must be wintered in a minimum temperature of 50 degs. BYFLEET.

NOTES AND REPLIES.

Anemone fulgens.—You would greatly oblige if you could give any hints in GARDENING ILLUSTRATED which would throw light on the cultivation of *Anemone fulgens*. With me, in a mixture of loam and leaf-mould, well drained, it flowers for the first season pretty well, after that it does no more good. And yet I hear of people declaring how it increases. I am inclined to give it up altogether.—R. L. ROUTH, *Banbury*.

[The cultivation of this fine scarlet Windflower in your county should not be fraught with the least difficulty, unless there is some peculiar local cause of which you afford us no information. The plant is usually a success in sunny gardens, and fails in those much shaded or where shade and a heavy, more or less retentive soil obtain. Generally speaking, the freshly imported roots do well the first year, and we know instances in rather warm counties and with a certain amount of chalk in the rather heavy soil of the plant succeeding permanently when planted in Grass. For garden decoration, however, we suggest the warmest and sunniest spot you can find, and planting not later than October. If your soil is heavy or clayey, add quite a third of sharp grit where the tubers are planted—that is, mixing the sand freely with the other soil and finally surrounding the tubers also with sand. After the first flowering it may be well to lift the roots after the leaves are quite ripened off, and give them a thorough resting in some open shed through which a free circulation of air is passing. After this treatment replant them as before, preferably in a fresh spot.]

Meconopsis chelidoniifolia.—This is exceedingly graceful. It comes from Szechuan in Western China, and has been distributed generously from Glasnevin, where it first flowered in Europe. As it is quite hardy, a good perennial, and, moreover, very easily propagated, it ought to be found before long in every good gar-

den where a cool, half-shaded position can be spared for it. I brought home a tuft of young plants from Glasnevin a year ago last April, divided it, and planted the resulting pieces in two clumps. Those among some Ferns in rather rich, cool soil did best and threw up slender, leafy stems, but did not flower last year. The tallest of these stems fell over, and I was delighted to find in the autumn that where they touched the ground every axil had rooted and produced a little plant. This spring each plant has shot up a stem, which arches over with the weight of the many heart-shaped flower-buds on the terminal shoot, and the lesser zigzag sprays that branch out from the leaf-axils of the central stem.—E. A. BOWLES in *Garden*.

Sweet Peas.—Judging by the scarcity of notes on Sweet Peas in GARDENING ILLUSTRATED, it may be inferred that there is something of a slump in them. Not, perhaps, from a garden point of view, for, no doubt, they are being as largely grown in that way as ever, but there does not now seem to be the same booming of new varieties, nor the same amount of writing concerning their merits from "experts." With all its good qualities the Sweet Pea was never really worth the position which it assumed, for some years, in garden literature. It was, as has been previously the case with other flowers, forced to the front by the efforts of enthusiasts, and, again as is generally the case, these very enthusiasts are responsible for its partial eclipse. The huge flowers, stems, and foliage with which we were familiar on show benches created a positive feeling of repulsion among many admirers of Sweet Peas, and the meaningless introduction of variety upon variety—the majority of them differing but little from others in cultivation—also tended to become a weariness to those who wished to keep abreast of the times. That the Sweet Pea is a most valuable stand-by for cutting cannot be denied, and if the present slump results in a return to its cultivation in a saner form so much the better. Grown naturally the blooms of Sweet Peas are among our fairest flowers, but when, like Chrysanthemums, they are taken under the wing of the exhibitor, their usefulness and their beauty alike vanish.—KIRK.

Scabiosa ochroleuca and S. caucasica.—The flowers of these, used in combination, make a lovely table decoration, the soft primrose-yellow of *S. ochroleuca* harmonising perfectly with and setting off the delicate lilac-blue shade of *S. caucasica*. Both of them flower on long, stiff stalks, so that they are ideal for cutting, and they last a fair time in water when cut. *S. ochroleuca* is the easier of the two to grow, and in any good garden loam, either in full sun or in partial shade, it grows like a weed. It flowers profusely during June and July. *S. caucasica* is rather more particular, and prefers a light and very stony soil in sun. Like *S. ochroleuca* it is very easily raised from seed, and when it finds itself in congenial quarters it improves year by year. The seedlings vary considerably both in colour and in habit, some having leafy bracts round the flowers, which do not improve their appearance. There is a white variety, but I do not care for it.—N. L.

Spiræa Aruncus.—The Spiræas are a moisture-loving family, but this handsome species seems almost indifferent in its tastes. I have a large plant growing in an ordinary raised border of rather dry loam, and it is a magnificent sight just now with twenty to thirty great snowy plumes of blossoms, making a striking object in the garden. It is a somewhat

slow-growing plant and is not seen at its best until it has been established for some years, but where there is plenty of room it is well worth growing.—N. L.

OSTROWSKIA MAGNIFICA.

This is without doubt one of the noblest of hardy herbaceous plants. A group of vigorous plants in full flower has a magnificent appearance. The blossoms, as seen in the illustration, are each fully 6 inches in diameter, whitish with a lilac suffusion throughout, and satin-like in texture, borne on stout stems, each from 5 feet to 7 feet in height. Unfortunately it must be considered a somewhat capricious plant as it is not a success in every garden. Even when apparently permanently established it occasionally dies unaccountably. A heavy soil to which has been added plenty of old mortar-rubble is evidently to its liking. With me it succeeds splendidly in such a soil planted under a wall having a south-east aspect. The only protection afforded the plants is a few Spruce branches placed

they all came up, looking very healthy, none of them bloomed. I see the plants depicted in your paper were planted at the same time as mine were, and I should be greatly obliged if you could tell me why mine have not flowered and what I ought to do to make them grow as well as in your illustration?—T., Loughton, Cloughjordan, Co. Tipperary.

[There may have been too much shade. Soil should be deep sandy peat and leaf-mould. The best plants we have seen of this were grown on the cool side of a wall in the Glasnevin Botanic Gardens.—Ed.]

ROYAL HORTICULTURAL SOCIETY

AUGUST 1ST, 1916.

INTEREST of a special character attaches to the meeting held on this date by the first exhibition of hardy British-grown flower-bulbs being held in conjunction therewith. From many points of view this latter must be regarded as a success, though it was a matter for surprise, seeing the far-reaching, almost national importance of encouraging to the full home industries at this time, that a much larger

Nottingham were also on view. Tulips from Wisbech and Spalding merited the highest praise, as did also the Hyacinths from the first-named district. Rarely, indeed, has such produce been seen. For the rest the wonderful collection of Gooseberries from Langley attracted the attention of everybody, a remarkable lot of mid-season Peas (100 varieties) from the Wisley trials also coming in for a fair share of attention. Phloxes and other hardy flowers were well shown, an extensive collection of Hart's Tongue Ferns (*Scolopendriums*) from Edmonton presenting a most cool and refreshing appearance. Gladioli also constituted a feature in an exhibition of unusual interest.

HARDY FLOWERS.

A plant of some importance to gardeners, which has yet to find its way into general cultivation, is *Thalictrum dipterocarpum*, a recent introduction from China. Of graceful habit and with violet-blue sepals, it is both elegant and attractive. It was shown by Mr. James Box and stood out well in a handsome grouping of the best hardy flowers. The finest Phlox novelty seen at this meeting was *P. Aubrey Alder*, whose salmon-scarlet flowers and blackish stems make it quite distinct. It gained an Award of Merit in the Phlox trial last year at Wisley. Mr. W. Wells, junr., had a big stand of it, and another of the new *Delphinium*, Mrs. H. Kaye (dark purple and violet), which also gained an Award of Merit at this meeting. Mr. H. J. Jones, Limited, also had some good novelties in herbaceous Phloxes, *Leonie Cobb* (pale salmon) and *Evangeline* (self-salmon) being among the more pronounced of these in a standard collection in which the finest of these good border flowers were remarked. Quite one of the most charming of new alpine Bellflowers is *Admiral Sir John Jellicoe*, a dainty thing in palest sky-blue, 4 inches or so high, that has resulted from crossing *C. Waldsteiniana* and *North Star* of the carpatia set. Lord Kitchener is a Bellflower of the *Fergusonii* and *Hendersonii* type, giving an impression of *pyramidalis* influence. Both were exhibited by Messrs. T. Grove and Sons. The prettiest thing of recent introduction and choice withal in Mr. G. Reuthe's collection was *Astilbe simplicifolia*, whose feathery white plumes of 9 inches high appear profusely above pointed heart-shaped, deeply-notched foliage. It is of quite alpine character. *Solidago rigida* is the most golden-coloured; "Golden Rod" we have seen, minus the weedy commonplaceness of so many of its tribe. It and the lovely *Romneya trichocalyx* were conspicuous items in a group from Messrs. Wallace and Co., which also teemed of the newer *Astilbes* so valuable for moist spots in the open or for gentle forcing. The Donard Nursery Co. sent a lovely lot of flowering examples of *Sparaxis pulcherrima*, obviously from the ordinary pot-grown, nursery-plunged stock than which nothing could afford better proof of the genial Irish climate whence they came. Graceful and beautiful to a degree, the array of pendent blossoms rendered the exhibit a chief attraction. A 3 feet high example of *Desfontainia spinosa* full of its gold and scarlet blossoms, *Styrax japonicum* (white), and the curious *Lomatia pinnatifida*, which is not generally hardy, were also from the same source. Mr. G. W. Miller's best plant was the new rosy-crimson *Astilbe Gloria*, in which the inflorescence is more densely arranged than usual, but the rich colour is its chief attraction. The most striking object in a large collection of plants from Mr. L. R. Russell was *Erythrina crista-*

Part of a group of *Ostrowskia magnifica* at Lilford Hall, Oundle, Northants.

around them in spring to ward off late frosts. In making a bed for the *Ostrowskia* this should be fully 3 feet deep, as the Carrot-like roots descend to a great depth. Perhaps the best method of establishing this plant is to raise seedlings, planting these out when about 6 inches high in the soil recommended. Seedling plants usually take about four years to reach the flowering stage. The roots are exceedingly brittle, and it is almost impossible, even with the greatest care, to lift a plant from the open ground without breaking them, this rendering its transplanting without damage most difficult. F. W. G.

Lilford Gardens, Northants.

Cypripedium spectabile.—I was much interested in the note on and picture of *Cypripedium spectabile* in your issue of July 29th, page 371. Two years ago next autumn I bought three of this Orchid, and planted them in a moist, shady spot, which I thought would suit them, mixing in peat with the soil before putting the plants in. The first spring after planting the three plants came up, but only one of them flowered, and last spring, though

number of growers did not participate in it. It may be that in large measure many of those who grow chiefly for the wholesale trade or others who cultivate extensively—almost exclusively—for market work were prevented from showing their produce, owing to shortness of labour, or difficulties of transit, or both. At the same time in a matter of such exceeding importance occasion should have been taken to demonstrate the vast superiority of British-grown bulbs, a fact which, if well known to cultivators and specialists, is insufficiently recognised by the great flower-growing public, who each year send vast sums of money abroad. Of the show itself—particularly the Daffodil classes—it would appear that, in the main, exhibitors had laid themselves out to showing produce of giant size to the exclusion of the much more useful commercial article. Giant "mother bulbs," indeed, were frequent, some from Ireland surrounded by a numerous family indicating the great possibilities of bulb cultivation in that land. Bulbs of the highest quality, however, from Cambridge, Lincoln, and

galli, which, though among the older-cultivated plants, is in the nature of a novelty to a large number. The brilliant crimson-scarlet flowers are a great attraction. Sweet Peas were very finely shown by Mr. Bolton and Messrs. Piper. A pretty new pink, *Dianthus deltoides flore-pleno*—the flowers are semi-double and in other respects replicas of those of the typical kind—was sent by Messrs. Baker. While gaining no award, it is likely to be of considerable service for rock garden work. *Scabiosa caucasica* was grandly shown by this firm. Gladioli of the finest description and in great variety were from Messrs. J. Kelway and Sons, whose two novelties, *Wraith* and *Phyllis Kelway*, are hybrids showing *primulinus* influence. That last named is an all-yellow variety of much beauty and purity of tone. It is also very handsome. *Empress of India*, of intensely dark crimson, was very fine.

ROSES.

Four novelties of much merit in a collection from Mr. Elisha Hicks stood out from all the rest. These were *Joanna Bridge* (semi-double), cream and pink, with a wonderful spread of roundly-formed petals, being the most conspicuous of all, *Candeur Lyonnaise* (big double white), *Mrs. Dunlop Best* (apricot), and *Red Letter Day*. Rev. J. H. Pemberton showed the new hybrid Musk Rose, *Pax*, which also possesses the Musk perfume. It is white-flowered and showy.

HARDY FERNS.

A collection of upwards of a hundred varieties of Hart's Tongue Ferns (*Scolopendrium*) was among the most refreshing and cool-looking exhibits staged at this meeting. Well grown and well staged, their dark, glossy, green fronds were welcome amid the heat and flower gaiety of the occasion. Such indispensable crispum forms as *Bowdeni*, *Grayi*, *latum*, and *robustum* were very noticeable, while of the tasselled set *grandidens* and *corymbiferum* were among the more distinct.

DRY BULB SHOW.

In the important class for twenty varieties of Daffodils twenty bulbs of each the Donard Nursery Co. were placed first, with a truly wonderful collection of mother bulbs. Messrs. R. H. Pearson were second. There were eight collections. In the Tulip class Mr. G. Monro, junr., was first, and Messrs. R. H. Bath second, both showing magnificent produce. For thirty varieties of bulbs and tubers, Daffodils and Tulips excluded, Messrs. Wallace were first and Messrs. Barr second, Mr. G. Monro, junr., being awarded first for an exhibit of market Daffodils in ten varieties.

FRUIT AND VEGETABLES.

Outstanding novelties in this section were Red Currant Laxton's Perfection, the finest Red Currant yet introduced, its glossy crimson-scarlet fruits in racemes of a score or more being a great attraction. Fruiting bushes of it also demonstrated its prolific bearing qualities. It is essentially a dessert Currant, though alike valuable for cooking. Plum Early Laxton (River's Early Prolific and Fraser's Early Yellow) shows a great advance in earliness. Both were shown by Messrs. Laxton Brothers, of Strawberry fame, and secured Awards of Merit. The new Black Currant "Blacksmith," also raised by this firm, is full of promise. Fruits of giant size, fine flavour, and abundantly produced, the variety appears to require no further recommendation. In short, it appears unique. A collection of upwards of a hundred varieties of

Gooseberries, gathered fruits, and single, double, and triple cordon trees, demonstrating how best to grow these fruits to attain perfection, was among the finer exhibits of a good meeting. No new variety was on view, though such high-class dessert varieties as *Langley Gage*, *Golden Gem*, and *Langley Beauty* will require some beating in this direction. These were well shown by Mr. J. C. Allgrove. From the Society's gardens at Wisley mid-season culinary Peas to the extent of a hundred varieties were placed before the Committee.

A complete list of the certificated plants and fruits, as also the list of medals awarded, will be found in our advertisement columns.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM AUGUST 2ND. — *Arundo conspicua*, *Ceanothus* (in variety), *Buddleia variabilis*, *B. globosa*, *Spiræas* (in great variety), *Ozothamnus rosmarinifolius*, *Philadelphus* (late-flowering variety), *Rhus* (in variety), *Clethra arborea*, *C. alnifolia*, *Calycanthus floridus*, *Spartium junceum*, *Carpenteria californica*, *Metrosideros floribunda*, *Berberis Wilsoni*, *Colutea arborescens*, *Escallonias* (in variety), *Hydrangeas*, *Nandina domestica*, *Cistus ladaniferus*, *Andromedas*, *Hypericums* (in variety), *Jasminum affine*, *J. humile*, *Hardy Fuchsias* (in variety), *Honeysuckles* (in variety), *Clematis* (in variety), *Indigofera Gerardiana*, *Tricuspidaria lanceolata*, *Viburnum coriaceum*, *Deutzia scabra fl.-pl. purpurea*, *Olearia nummulariæfolia*, *Veronicas* (shrubby), *Bocconia cordata*, *Raphiolepis ovata*, *Forglives* (in variety), *Delphiniums*, *Phloxes* (in variety), *Helianthus*, *Verbascums*, *Helonium pumilum*, *Erigerons*, *Anchusas*, *Lavateras*, *Chrysanthemum maximum* (in variety), *Echinops*, *Eryngiums*, *Acanthus*, *Galegas*, *Centaureas*, *Tritomas*, *Romneya Coulteri*, *Achilleas* (in variety), *Aster Amellus*, *Ænotheras* (in variety), *Geums* (in variety), *Nepeeta Mussini*, *Lobelia cardinalis* (in variety), *Gazania splendens*, *Verbena venosa*, *Santolina viridis*, *S. alpina*, *Glossocoma clematidea*, *Heucheras* (in variety), *Aubrietias* (in shade), *Sedums* (in variety), *Convolvulus mauritanicus*, *Linarias*, *Sagina glabra*, *Oralis floribunda*, *Onosma tauricum*, *Tradescantia virginiana*, *Veronica Lyalli*, *V. candida*, *Androsace lanuginosa*, *Silene Schafta*, *Plumbago Larpentæ*, *Mimulus* (in variety), *Erinus*, *Primula capitata*, *Dianthus* (in variety), *Gentiana septemfida*, *Francoa sonchifolia*, *Banffia petræa*, *Æthionema coridifolium*, *Antirrhinum Asarina*, *Potentillas* (various), *Linums*, *Calceolaria amplexicaulis*, *C. mexicana*, *Salvias*, *Ageratum*, *Heliotropes*, *Petunias*, *Verbenas*, *Phlox Drummondii*, *Stocks* (in variety), *Antirrhinums* (in many colours), *Pentstemons* (in variety), *Tufted Pansies* (in many varieties), *Cosmos*, *Candytuft* (in variety), *Leptosiphons*, *Godetias*, *Clarkias*, *Alstræmerias*, *Canterbury Bells*, *Sweet Sultans*, *Begonias*, *Verbenas*, *Dianthus Heddewigi*, *Gladiolus* (in variety), *Hyacinthus candicans*, *Montbretias*, *Mignonette*, *Annual Larkspurs*, *Pelargoniums* (in variety), *Carnations*, *Campanulas* (dwarf and tall) (in many varieties), *Sweet Peas*, *Roses* (many species and varieties), *Lysimachias*, *Epilobiums*, *Solidagos*, *Lythrum roseum*, *Senecio Clivorum*, *S. japonica*, *Iris Kæmpferi*, *Sagittaria sagittalis*, *Water Lilies* (in variety).

THE WEEK'S WORK.—During the past week a great deal of time has been given up to watering, for, although deep-rooting subjects have not suffered, shallow-rooting plants quickly feel the drought. Many of the earlier varieties of Climbing Roses have ceased blooming. These are being overhauled and some of the old growths cut out to allow the young basal shoots to be retained in their places. There are usually many more shoots than are required, and the weaker ones should be cut clean away, retaining only sufficient of the stronger branches to furnish the allotted space. It is a mistake to tie in too many shoots, for unless they are ripened properly the results will not be satisfactory next

season. Sweet Peas have grown to an unusual height, and it has been necessary to afford extra support. Where the plants are in rows, stout poles were inserted firmly in the ground at intervals of a few yards, and a row or two of string stretched between them. Some of the old plants of Tufted Pansies (*Violas*) have been cut down to encourage young growth suitable for cuttings. From these plants good cuttings will be obtained by the end of the present month or early in September. Tufted Pansies may also be propagated at the present time by dividing the old plants and planting them in a border, but I prefer young plants obtained from cuttings. Cuttings of many plants put in a month ago into a bed of sand (as described on page 338) are now well rooted. We are now potting them up singly in small pots, using a sandy soil. After potting they are placed in a cold frame, which will be kept close and lightly shaded, spraying the plants twice daily until they get over the check of removal, after which they will be gradually hardened off.

F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Fruit garden.—The layering of Strawberry runners should now be brought to a conclusion. Those layered early in the month and which will soon be ready for severing from the mother plants must be kept well supplied with water. When first removed, it is best to place them close together in partial shade for a few days, after which pick out those required for pots and stand them by themselves. Potting should be done before the plants become pot-bound. The budding of stocks with suitable kinds of fruits may now be proceeded with. Trees grafted last spring should have the young growths made secure against damage from rough winds by tying them to bamboo canes lashed on to the branches below where the scions were inserted. In the case of wall-trained trees and espaliers this is, of course, unnecessary, as the shoots can be fastened either to the wall or wires. Red and White Currants trained on walls facing north should have all side shoots shortened to four buds and be securely netted to preserve the fruit from birds. The young canes of autumn fruiting Raspberries should be thinned out, dispensing with the weakest and retaining sufficient of the stronger so that when tied to the wires they stand about 9 inches apart. Cut out the old canes of the summer fruiters and burn them. Then thin out the canes of the current season's production, rejecting the weakest and those of medium strength, and tie to the wires the best and enough of the strongest to stand when finished about 6 inches apart. Where the old-fashioned method of growing them in clumps and tying the canes to stakes still obtains, from seven to nine new canes should be retained on each, and be loosely fastened to the stakes. Any thinning of fruit required in the case of Apples or Pears—which will certainly be the exception this year—should now have attention, leaving the best-shaped and such as are in a more forward condition as a matter of course.

Orchard-house.—Trees laden with fruit, such as late Peaches, Nectarines, Pears, Plums, and Apples, must be carefully attended to in the way of watering, as any neglect in this direction will lead to premature ripening and dropping of fruit. Judicious feeding, both with diluted liquid and artificial manure, is very necessary, seeing that the pots are so full of hungry roots, and a renewal of the mulch on the surface should take place as soon as that previously applied becomes exhausted. Until the fruit begins to ripen, the foliage needs to be copiously syringed morning and afternoon, and in the case of Plums the water used should be clean and free from lime, otherwise the fruits will be marked and their appearance spoilt. Free ventilation is necessary, especially when the ripening has to be retarded as much as possible, while to promote a cool and healthy internal atmosphere, both paths and the surface of the bed on which the pots are stood or plunged should be frequently damped in fine weather. Trees from which the fruit has already been gathered may be moved outdoors and stood on

a hard base and in full sun that the wood and buds may become the more thoroughly ripened. If boards are stood on edge in front of the pots—some loose litter will do equally as well—watering will need less frequent attention.

Pot Vines.—Canes required for forcing early next season should now be moved outdoors for the ripening of the wood and buds. A good position for them is the base of a hedge facing south, as the canes are then readily afforded the security and support they require to prevent them becoming damaged in any way while the sun has full play on the wood and buds. A wall answers the same purpose. In either case watering must be strictly attended to, but to lessen labour in this direction adopt the same measure for the prevention of undue drying out of moisture as recommended for orchard-house trees.

Pinks.—These should be propagated now either by the rough-and-ready method of planting tufts containing seven to nine growths with a portion of the old stem attached or by inserting cuttings or pipings in prepared soil and covering with handlights. For ordinary purposes the former method answers every requirement. For the working up of stock of a new or scarce variety the latter is the preferable mode.

Pentas carnea.—This is a most useful plant for indoor decoration during autumn and winter. The plants should now be shifted into their flowering-pots, 6-inch and 7-inch, and grown on in heat, frequently stopping the young growths until hushy specimens of the required size have been secured, when they may be allowed to flower.

Tuberous Begonias.—Plants required for autumn decoration and now coming into bloom require assistance at the roots in the form of diluted liquid alternated with a pinch of Clay's fertiliser. A light, airy position, shading them from direct sunlight, will now both suit their cultural requirements and prolong the blooming period. Any of the seedlings raised last spring, whether of single or double varieties, that are of exceptional merit should be labelled and taken care of.

A. W.

MIDLAND COUNTIES.

Peaches and Nectarines on a south wall are very backward and need more sunshine. It is necessary to frequently look over the trees, keeping the lateral shoots persistently pinched in at the first leaf. The fruits are fully exposed to light and air by removing a few of the leaves covering them, or fastening them back. Trees carrying heavy crops are assisted by an occasional application of liquid-manure. All shoots required for fruiting next season are carefully tied in, removing any surplus ones that have been overlooked in order to avoid overcrowding.

Apples.—Although early-summer pruning of the Apple is not advisable owing to it producing a profusion of sappy growths, the summer pruning of the bush, espalier, and similar trees that have their growth restricted should now be completed. In pruning, it is necessary that the operator knows the difference between ordinary wood growths and fruit-bearing spurs—i.e., short, sturdy growths which ultimately terminate with a fruit-bud. Some varieties of Apples, such as Jacob's Seedling, Irish Peach, Worcester Pearmain, and Cornish Gilliflower produce a great portion of their fruit upon this principle. The removal of such growths would consequently cause failure. On young trees sufficient terminal and other shoots to properly furnish them should be retained. Attend to the thinning of fruit where it is necessary, but in our case, except in the case of a few espaliers, it has not been necessary this season. Where aphid has been troublesome, the trees and their fruit will be benefited by being thoroughly washed with the garden engine.

Chrysanthemums will now be afforded a good top-dressing, first removing all weeds and suckers, and stirring the surface-soil with a pointed stick. A suitable top-dressing consists of good loam and horse-manure passed through a sieve, adding a 5-inch potful of bone-meal to every bushel of soil. See that the

ball of soil is moist before applying the top-dressing, and ram it firmly with a potting-stick. The shoots need to be regularly tied and made secure against wind. An occasional spraying with Quassia extract keeps aphid and other insect pests in check.

Pelargoniums of the show and fancy sections will now be pruned. Show Pelargoniums should have nearly the whole of the current year's growth cut away, but the fancy varieties must not be pruned so hard. In each case the grower must be guided by the shape of the plant. After the plants are pruned and cleaned they are placed in a cold frame, taking care not to crowd them. Lightly syringe the plants twice a day, but for the present give no water at the roots. The frame should be well ventilated.

Calanthes are now growing vigorously and require an abundance of water at the roots. They are afforded alternate waterings of liquid cow-manure. Many young roots are appearing on the surface of the compost. A thin layer of good fibrous loam will be laid over them, and into this they will quickly enter.

Malmison Carnations.—The one-year-old plants having passed out of flower are being repotted, giving each a good shift according to the strength of the plant. A suitable compost consists of good loam, a little mortar rubble, wood ashes, crushed oyster-shell, silver sand, and a small quantity of bone-meal. The pots must be clean and well drained, and the soil made very firm. After repotting, the plants are placed in a well-ventilated frame and carefully watered. The earliest layered plants will soon be ready for potting. It is a good plan to sever the layers from the parent plant a few days before potting. Pots 3 inches in diameter are a suitable size. The compost for these young plants should be the same as for the old plants, only omitting the bone-meal. Pot firmly, and keep the collar of the plant above the soil.

Cauliflowers.—The main crop, now turning in for use very fast, is of exceptionally good quality. Tie the leaves together directly a plant shows signs of developing a curd, in order to have the heads white and of the best quality. When it is found that they are coming into use too fast, some of the plants may be taken up and placed in a cool shed, where they will keep good for many days. There is still time to plant Cauliflowers for early winter supplies, selecting rich soil in a sheltered situation. If the variety Early London is put out now, the plants may be expected to yield heads throughout October. Fresh plantations of young Cauliflowers should be watered freely with liquid-manure and the ground between the rows stirred frequently. Late Broccoli, Kales, and winter Cabbage, as well as Savoys, may still be planted on ground cleared of Potatoes and other early crops. Give a slight earthing up to earlier-planted Savoys and winter Cabbage. The seedlings from the first sowing of spring Cabbage are now appearing, so a second sowing will be made. A sowing of Chervil will be made now, this being frequently in demand for flavouring during the winter months. As soon as large enough, the young seedlings are thinned out to about 6 inches apart.

Parsley.—Plants raised from seed sown a month ago are now ready for thinning. Those removed from the rows will be planted in a sheltered position, where they may be covered with box frames during severe weather. If the seedlings are planted at 8 inches apart they will have room to develop into good strong plants before the season is far advanced. Liberal supplies of water are afforded the roots, and when the plants have grown to a good size they will be cut close to the ground to encourage a stocky growth.

Leeks.—A further plantation of Leeks has been made to provide supplies next April and May. The plants are allowed a distance of 1 foot between the rows and 8 inches in the rows. Give plenty of clear water to the roots until they are established, and keep the soil loose by frequent hoeing. Leeks planted early in the season will derive much benefit from good waterings of liquid manure. Place a little soil around the stems as growth advances. The Leek is a cross-feeding subject,

and, unlike most vegetables, the largest specimens have the mildest flavour.

Endive.—To ensure a continuous supply, frequent small sowings will be made during the next four weeks. Plants raised from earlier sowings are put out as they become ready in rich soil on a site facing south-west, allowing a distance of 12 inches between the plants.

F. W. GALLOP.

SCOTLAND.

Plants for spring flowering.—In the course of the week a look round was given to the hardy border plants with a view to selecting such as may be of value for the greenhouse in the spring. The restrictions upon the importation of hulks will by many be felt, but there are many border plants which, if judiciously used, may be relied upon to give a good account of themselves, while, in addition, their use is a breakaway from the stereotyped flowers of spring. The Plantain Lilies (Funkias) of all kinds are amenable to cultivation in pots, and very hardy they are. These will stand a considerable amount of forcing, but need from the beginning to be lavishly supplied with moisture. *Dielytra spectabilis* and Solomon's Seal, as well as *Hoteia japonica*, are too well known in this connection to need more than a passing reference. The value of the Day Lily (*Hemerocallis flava*) for greenhouse work is less known. It is, however, a fact that good-sized clumps of this popular plant may be accelerated by placing them in a moderate heat. *Montheletias*, too, are, generally speaking, a novelty under glass. These will not endure forcing, but if grown quite coolly they are very much appreciated in the late spring. All of these I have used at one time or another for the purpose referred to, and with satisfactory results. Therefore, strong pieces were marked in order that no mistakes may occur when the time for lifting comes round. In addition to these things, there are, of course, great possibilities in the way of using Stocks, Wallflowers, Canterbury Bells, and Forget-me-not, so that, for once in a way, the loss of the usual batches of bulbs may be endured with equanimity.

Hardy fruit.—The weather having become warmer and brighter, progress is now being rapidly made. Raspberries, Strawberries, Red Currants, and White Currants ripening practically simultaneously, picking takes up no inconsiderable portion of the time, but is being persevered with as occasion permits. Naturally, the soft fruits are dealt with first. In the case of Raspberries, a considerable proportion of the crop is bottled. For this purpose the first berries are preferred, as they are larger, firmer, and altogether finer than those which ripen at a later date. The bottles are filled direct from the canes, and conveyed to the kitchen. Gooseberries are later than usual. Wall fruit, encouraged by the finer weather, is now going ahead, but here, too, the crops will be decidedly late. Apples are a thin crop, alike on walls and in the open, with the exception of a collection of young trees on the Paradise, which have fruited freely.

Present sowings of flower seeds may yet include such things as Pansies, Lupins, Canterbury Bells, Aquilegias, Hollyhocks, and supplementary sowings of Primulas, Calceolarias, and Cinerarias. In the case of Pansies, a cool, but not shady, place is to be preferred. Seedling Pansies are always very useful, their blooms being larger than those from plants propagated from cuttings. These blooms from seedling plants may not, of course, be of such high quality or so well marked as flowers from named varieties, nevertheless they are quite as good for general purposes. Tufted Pansies may also be sown. Some varieties, such as Primrose Dame, come quite true from seed.

Cleaning, etc.—With the more favourable weather conditions an effort was made to deal with weeds, which had become more prominent than is usually the case. All the available labour was concentrated on this work, and at the week's end everything was in a more satisfactory condition. It may be mentioned, in this connection, that the present week is the first one of the season in which the mow-

ing-machine had not to be taken off on account of rain.

Woodland.—During the week woodland walks received their usual annual clean up. Being overhung by trees, Grass and weeds are not very troublesome, and a thorough clean up about midsummer keeps the walks in pretty good order until the fallen leaves require to be gathered.

Shrubberies.—Foliage at the present time is more in evidence than bloom, and, owing to the dripping season, is more luxuriant than usual. At the same time there is a considerable amount of bloom. Fuchsias of different kinds are very free and showy. Veronicas, and especially *V. Traversi*, are in fine form, and the shrubby *Spiræas* begin to be telling. Among these, *S. ariaefolia* and *S. Bumalda* are noteworthy. Some large pieces of *Rosa rugosa* have bloomed consistently for some time. The Elders are in flower, the variety *rubra* being well worth attention. It is not such a pest as the common sort, which is grubbed out wherever it is noticed. *Coton-easter frigida* is full of flower, this auguring well for a profuse display of berries. The False Heath (*Fabiana imbricata*) still blooms, *St. John's Wort* and other odds and ends adding to the attractions of the shrubberies at this season of the year.

Vegetable garden.—All vegetable breaks have been thoroughly hoed. Potatoes are lifting well, much better than was anticipated after the backward weather experienced since the time of planting. Indications point to the second-early varieties being better than the early sorts, *Beauty of Hebron*, *Puritan*, and *Sir John Llewellyn* being remarkably promising, if haulm is any criterion. Parsley was sown, as was a bed of Carrots, and some lines of Prickly Spinach, and another line of Spinach *Ecet*, which is always useful in autumn, and especially so in spring. A further sowing of an early variety of Cabbage was got in. Lettuces were sown, and preparations were made for the forthcoming sowing of autumn Onions. More of these will be sown than is generally the case. They will be thinned as soon as possible, and the best of the thinnings transplanted. A few more Early *Ulm Savoy* and a final lot of Cauliflowers were planted. It is to be hoped that Peas and Broad Beans may now come away in response to the finer weather. Up till now, although pods are very numerous, they have not filled well. W. McGuffog.

Balmæ Gardens, Kirkcubright.

Royal Horticultural Society's Lindley Library.—The Lindley Library of the Royal Horticultural Society has been presented with a magnificent collection of books from the library of the late President of the Society, *Sir Trevor Lawrence, Bart., K.C.V.O., V.M.H.*, whereby many gaps which previously existed on the shelves are now filled. The volumes are beautifully bound in half calf, are all valuable, and in many cases rare. They bear a book plate inscribed: "Presented to the Lindley Library of the Royal Horticultural Society in memory of *Sir J. J. Trevor Lawrence, Bart., K.C.V.O., V.M.H.*, President of the Society from 1885 to 1913, by his children, 1916." Among the books may specially be mentioned:—"Coloured Engravings of Heaths," *H. C. Andrews*, 4 vols.; "The Naturalist on the River Amazon," *H. W. Bates*, 2 vols.; "The Flowers of Japan," *J. Conder*; "British Entomology," *J. Curtis*, 8 vols.; "Illustrations of British Mycology," *Mrs. T. J. Hussey*, 2 vols.; "Illustrations of Orchidaceous Plants," *T. Moore*; "Select Orchidaceous Plants," *R. Warner*; "Iconographie des Orchidées," *Lindénia*, 17 vols.; "L'Orchidophile," 10 vols.; "Journal des Orchidées," 7 vols.; "La Belgique Horticole," 35 vols.; "Revue de l'Horticulture Belge," 25 vols.; "Journal of Botany," 45 vols.—*W. Wilks*, Secretary, Royal Horticultural Society.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Madonna Lilies failing (*J. E. Longson*).—Your Lilies have no doubt been attacked by that terrible disease (undoubtedly of fungoid origin) which has destroyed this Lily in so many gardens in which at one time it used to do so well. Various remedies have been tried, but up to the present none of them seem to have given general satisfaction. Spraying the plants with a solution of 2 oz. of sulphide of potassium dissolved in 3 gallons of water has been recommended, at the same time removing any decaying foliage and burning it. Lifting the bulbs and shaking them up in a bag of sulphur have in some cases proved efficacious.

TREES AND SHRUBS.

The Poison Ivy (*Rhus Toxicodendron*) (*John Wyatt*).—This ought to be known to everyone who is interested in a garden, if only to know a plant that is well to avoid. It would really be a good thing if it were banished from gardens, for it is an extremely poisonous shrub and one which people who know nothing of its dangerous qualities would only be too glad to possess, for the ternate leaves assume brilliant hues in the autumn. The danger lies in the sap, which causes a kind of eczema, which has a decidedly unpleasant irritating effect, while bad attacks have been known to prove fatal. Some people appear to be immune from its harmful influence, while merely handling the leaves affects other people. A synonym which has misled many people is *Ampelopsis Hoggi*, under which name it is often found in nurseries and gardens. Needless to say, it has nothing to do with *Ampelopsis*.

FRUIT.

Peaches dropping (*K. F. Green*).—To imperfect fertilisation of the flowers may be traced the origin of the dropping of the fruit, and there is no remedy that can be applied to benefit the present crop. The vigour of the tree affords no solution of the difficulty because it is not the result of bad health, but rather the reverse. When Peaches are flowering it is never safe to trust to chance in the setting, for without artificial fertilisation the fruit may swell away for a time and then drop from premature softening accelerated by the unsound stone. Fresh-slacked lime applied in sufficient quantity to whiten the surface is a good remedy in such cases, applying it two or three times during the growing season. In the case of over-luxuriant growth, root-pruning, lifting, and placing the roots nearer the surface go a long way towards remedying the evil. Unripened wood will also cause the

trouble, while allowing the borders to get dry after the crop is gathered is also very often the cause of the trouble.

VEGETABLES.

Tomatoes not swelling (*A Reader*).—The cause of the fruits failing to swell is that the fertilisation was imperfect. In order to ensure this taking place the pollen should be distributed by passing the hand or a feather lightly, yet briskly, over each expanded truss of bloom about noon each day when the sun is shining and the atmosphere dry. Give as much air as you can, do not shade, and keep the atmosphere of the house dry. You are feeding too freely. Food given when the fruits are setting causes too much leaf-growth, and the flowers drop. Feeding is required only when the fruits are swelling.

MISCELLANEOUS.

Improving clay soil (*Miss Barton*).—In order to improve clay soil, such substances should be added as will render it more porous. Road grit, old mortar-rubble, wood-ashes, burnt vegetable refuse, leaf-mould, and fresh manure from the stable with plenty of straw in it are all good. The ground should be deeply trenched, and the bottom well broken up, mixing with it the materials above mentioned. You cannot expect any good results from such a soil unless you do this.

SHORT REPLIES.

A. M. Allen.—1, You may gather the pods as they ripen, or better wait until the pods and haulm are quite dry, then pull the haulm with the pods attached and thrash out, drying the seeds carefully before storing. 2, Dried Peas for winter use are saved in the same way. 3, The White or Green Flageolet are usually grown for their seeds, and are cultivated in the same way as the kinds the pods of which are used green. Allow the Beans to ripen thoroughly before pulling them, afterwards drying them and storing them.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*I. S.*—1, *Lysimachia vulgaris*; 2, *Astilbe japonica*.—*W. P. R.*—1, *Euphorbia Lathyris*; 2, *Linaria pallida*; 3, *Lonicera aureo-reticulata*; 4, *Alstrœmeria aurantiaca*.—*W. F.*—1, *Galega officinalis*; 2, *Agrostemma coronaria*; 3, *Sidalcea Listeri*; 4, *Scabiosa caucasica*.—*H. G.*—1, *Asclepias tuberosa*; 2, *Galega officinalis*; 3, *Matricaria inodora fl.-pl.*; 4, *Solidago Virgaurea*.—*M. A.*—1, *Lavender Cotton* (*Santolina incana*); 2, *Sidalcea candida*; 3, *Erigeron speciosus*; 4, *Campanula lactiflora*.—*S. D.*—1, *Sedum Sieboldi*; 2, *Fuchsia Riccartoni*; 3, *Salvia Horminum*; 4, *Olearia Haasti*.—*E. E.*—1, *Malope grandiflora alba*; 2, *Godetia Lady Albarle*; 3, *Platycodon grandiflorum*; 4, *Veronica prostrata*.—*E. S.*—1, *Phacelia tanacetifolia*.—*J. E. Kelsall*.—So far as we can judge from the flowers you send, the plant is *Sedum spurium*.—*T.*—1, *Linaria purpurea*; 2, *Campanula sp.*, should like to see fresher specimen; 3, *Lychnis Haageana*.—*Miss Ramsden*.—Cannot name with any certainty without fresh flowers.—*Morgan Williams*.—*Clarkia elegans fl.-pl.* *Salmon Queen*.—*Frank Hubbard*.—*Linaria pallida*.—*R. N.*—1, *Inula glandulosa*; 2, *Centaurea macrocephala*; 3, *Lathyrus rotundifolius*; 4, *Galega officinalis alba*.—*S. T.*—1, *Hypericum calycinum*; 2, *Deutzia crenata fl.-pl.*; 3, *Thalictrum aquilegifolium*; 4, *Chrysanthemum maximum*.—*J. P., B'head*.—So far as we can say without seeing the flowers you refer to, the yellow-flowered plant with dark spots is *Helianthemum formosum*.

Names of fruits.—*H. J. W.*—Apples: 1, *Keswick Codlin*; 2, *Beauty of Bath*.

Trial of winter-fruiting Tomatoes at Wisley.—The Royal Horticultural Society will carry out a trial of winter-fruiting Tomatoes at Wisley during the ensuing season. Seeds for trial (one packet of each variety) should be sent as early as possible to the Director, *R.H.S. Gardens, Wisley, Ripley, Surrey*, from whom the necessary entry forms (one for each variety) may be obtained.

THE TRUE LAUREL AND THE EVERGREEN CHERRY.

In the passage printed below from a letter sent to the daily papers the Duchess of Rutland helps in the misuse of the terms often wrongly applied in gardens to two trees commonly grown.

Would it not be a becoming symbol of gratitude for what the Empire has achieved, of honour to the dead whom the Empire has given, and of living love and faith in the thousands of the sons of the Empire still fighting and dying with us and for us for the ideals which inspire us all, if wreaths of Laurel and Bay should decorate these statues on the coming August 4, the second anniversary of the declaration of war, when in one single moment of time the scattered Empire knew that it was one, and united for ever?

This is another instance of the blundering about names common with us. The true Laurel (*Laurus nobilis*), often wrongly called the Bay Laurel, is the noblest evergreen tree we have, and both Duchesses and Lady gardeners should be told to use for it its own classical name. By natives of our islands it should be doubly cherished, from its ancient associations and the fact we may enjoy its fine form in the open air, whereas in northern Europe it has to be protected, and hence its extensive use in houses and winter gardens in cold countries. Such are its claims, however, that it is grown to a vast extent for this purpose in the Belgian nurseries. All the greater reason why its one simple name Laurel should be used and the term Sweet Bay discarded.

Next as to its use in gardens. The name being wrongly given to a totally different tree has, to some extent, led gardeners and planters to neglect or make a poor use of it. The coarse Evergreen Cherry is, owing to the confusion of name, often put to do its work. That being a coarse grower, to keep it in bounds leads to acres of mutilated objects in pleasure-grounds, and much harm has come from the practice. A very good use is to form backgrounds of this beautiful tree, for which purpose it is better than the Yew, Spruce, and various other trees often used in this way, with the gain that, in its case, shaving or clipping is unnecessary. In all our southern counties near the sea and in mild situations it should be used. In the same districts groups are very effective in pleasure-grounds. In the colder northern districts, where the tree is not hardy, those who care for it

might well grow it in sheds or cool houses, standing it in the open air in the summer.

It is well to remember that the Laurel is, naturally, when grown under favourable conditions, a tree of 50 feet high or more, and that it will attain the same dimensions in warm valleys round our own coasts, which knowledge should prevent our regarding it as a mere shrub.

THE EVERGREEN CHERRY (PRUNUS LAURO-CERASUS).

This also is a noble evergreen tree, and it deserves a good name. Bringing in the word Laurel in connection with it at all is wrong. It is as easy to say Evergreen Cherry as Evergreen Oak. This is an important matter, and when we use the right name we separate it at once from the Laurel. It is a noble tree if well used, but it has hitherto been often misused, particularly where it had to be clipped. Its true use is seen when we have it in a bold, picturesque group in the pleasure-grounds or home wood. Its form is very fine if allowed to grow in its own way and not mutilated as it often is. It has a number of interesting variations, narrow-leaved and other forms, some of which flower in a very pretty way. As an evergreen in mixed woodland the Evergreen Cherry gives a fine variety of colour and form, and some shelter for birds.

W. R.

NOTES OF THE WEEK.

Spiræa arborea.—Long used to the effect of Lindley's *Spiræa* one could not well expect anything finer, but the above named has broader plume-like masses of flower. It is said to be the most tree-like of the group it belongs to, and is a native of China. Seen at Myddleton House, mid-August.

Blue Lactucas.—These, often known as *Mulgedium*, are very useful in half-shady places in shrubbery or the wild garden, giving masses of tall blue flowers when good blue flowers are scarce. The one to avoid in the garden, *L. alpina*, is a graceful, tall plant, but once get it into the garden it is impossible to get it out. I saw it lately at Myddleton House in various safe positions.—W.

Ceanothus Gloire de Versailles.—This, although a trifle later than usual, is now, July 27th, in flower. In some districts it may succeed in the open, but although the climate here is milder than the average it is necessary to give *C. Gloire de Versailles*

the protection of a wall. The late Mr. Jeffery planted this fine shrub in the open in Captain Hope's garden at St. Mary's Isle, but while it grew to some extent it could never truthfully be described as a success.—KIRKCUDBRIGHT.

Epilobium hirsutum Apple Blossom.—

It is interesting to seek good forms of our native wild plants, and this, so constant in its wild state in every wet ditch, never promised much, but a white form with pink buds has been found on the banks of the river Lea and proves a very pretty water-side plant. Seen at Myddleton House.

Roscea cautioides.—Either due to the character of the soil or because of some variation among the plants, *Roscea cautioides*, as seen in gardens, apparently varies in depth of colouring. It is, happily, proving hardy, and I have met with it doing well in several Scottish gardens both last year and this. On a grey stone moraine it is not nearly so pleasing as it is in the garden of Sir Herbert Maxwell, where, in a border with a background of greenery, it looked exceedingly pretty this summer.—S. ARNOTT.

Chionodoxa in light soils.—Few spring flowers are so beautiful as the *Chionodoxas*, which seem to thrive in almost any soil except heavy clay. This spring I was astonished to see how they were thriving in a small garden at Camberley (West Surrey) under some large Fir-trees. The owner told me a few bulbs were planted some five years ago and they had only been replanted once. They had been allowed to seed every year and had increased more than double. They did not appear to object to the Fir needles.—J. CROOK.

Ourisia coccinea.—I am always unwilling to question the views of Mr. Jenkins, but there are places where it is quite unnecessary to lift and divide *Ourisia coccinea*. I know gardens where it flowers well annually and where it is never lifted, but allowed to grow on year after year. In one of these gardens pieces from the original mass have been tried in other parts of the garden, but have always failed. Mr. Jenkins' advice is certainly worth following in many gardens, but it would not be successful in others.—S. ARNOTT.

Raoulia australis.—This is one of the dwarfiest as it is the most silvery of carpeting alpines, the whole plant, even at flowering time, not more than a $\frac{1}{2}$ inch high. Too close and dense growing, per-

haps, to admit of much succeeding well if planted beneath it, a good use may yet be made of it in the rock garden by planting it near others of distinctive leaf character by way of contrast. In this way colonies of such diminutive subjects may well play a part in any good rock garden. It does not object to a little shade, though given good soil it is more silvery perhaps in sun.—E. H. J.

The Cape Pondweed (*Aponogeton distachyum*).—This ought to have a small tank or pond to itself, as, after it has become established, it has an extraordinary way of monopolising everything and of crowding out its neighbours. I know of a large Water Lily pond which gave an immense amount of trouble owing to the *Aponogeton* in pools in a streamlet which flowed into the pond having seeded, the seeds being washed down to the pond, where they germinated. The pond had to be cleaned out, but not before some of the *Nymphaeas* had been choked up and destroyed.—S. A.

Tropaeolum speciosum in Scotland.—I once saw a cottager digging Potatoes in a roadside garden in Scotland. The hedge next the road was scarlet with the flowers of *Tropaeolum speciosum*, and the thick white roots came up along with the Potatoes. "What will you do with these roots?" I asked. "Throw them away," was the laconic reply. I asked for some, which were willingly given—an awful almost. "Now," said the donor, "be careful' whaur ye pit it—it's the worst weed ye can ever get into a garden." And so it seemed to be there, and in other places northward, but with some it is one of the most capricious and stubborn of plants.—T.

Grinum Powellii and C. P. album.—A border of these bold bulbous-rooted subjects has for a long time past been providing a feast of flowers beside the economic house at Kew. Tall shafts of 5 feet or so high by the score—almost the hundred—could be counted, and remembering the succession of buds that such would carry the display has been one of long duration. The white form is particularly good at the moment, and if of somewhat dwarfer stature its lovely pure white bells are of giant size and of exceptional quality. Hardy and free-flowering, no bulbous-rooted subjects are possessed of a finer presence than these when rightly placed.—E. J.

Campanula grandis.—During the last half of June and early July this has made a fine show in many gardens on our poor Camberley soil. In a garden near me there is a big group many feet across in full sun. This was a mass of colour, the flower-stems 3 feet to 1 foot high. In the autumn of 1914 a few small plants were planted a foot apart. In another garden I saw it doing well amongst the Grass in a portion given up to bulbs in spring. This gave me the idea of its value to give colour in rough Grass after bulbs are over. In a cut state it is most enduring. I cut some when just opened, placing them in my sitting-room, where they looked well and lasted for some time.—WEST SURREY.

Orange Lilies and Larkspurs.—What charming effects can be made in the garden at this season with these plants alone. The contrast of colour as well as form is perfect. The tall purple spires of the Delphinium group beautifully with the spreading flat heads of the rich orange-yellow Lily. Here, then, are two common and inexpensive plants capable of producing striking and pleasing effects for a few weeks at this season. Those who contemplate planting groups of hardy flowers this autumn should not forget to

plant in proximity several plump bulbs of the orange Lily and strong clumps of the best sorts of Delphinium. Plant in good, deep, well-trenched soil, manure well the Larkspurs, and in the second season there should be an array of bloom as attractive as one could wish for.

Delphinium Queen Mary.—This was one of the most beautiful new Larkspurs at the Holland House Show, where Messrs. Bunyard grouped it on a lavish scale. The flowers are sky-blue with white centre, almost identical in colour with those of the old *Belladonna*, the flowers thrice as large and bearing some relation to that variety in the freedom with which its flower-spikes are borne.—E. H. J.

The Plum crop.—In a recent issue enquiries were made as to this crop. In this part of West Surrey the Plum crop may be described as fairly good, especially of such kinds as *Victoria*, *Early Prolific*, and others of this type. In my own garden trees of these have heavy crops. On one or two trees more than half had to be pulled off before stoning, although the trees are in an exposed position and had a big crop on them last season. I have a nice bush tree of *Kirke's* which blooms abundantly every year, but never gives more than a dozen fruits, while *Pond's Seedling*, by its side, bears well. I have seen *Kirke's* on bush trees at *Marriott's Nursery*, in Somerset, carrying enormous crops.—W. SUREY.

A Lily from the leaf.—Some six years ago, when I was living in Hampshire, I grew *Madonna Lilies*. I observed one day that one of the leaves was partially buried in the surrounding soil. On freeing it I noticed a tiny bulb like a pearl had formed at the end of the leaf. I watched it till the pearl grew to the size of a Pea, and the Pea grew to the size of a marble. Then I severed the bulb and potted it, and now it is blooming for the first time after all these years. Propagating by leaves is a known thing, but the growth of a bulb from a leaf seems unique and unusual, which is the reason I am sending you an account of it.—Mrs. E. Towgood, *Okhampton, Devon*.

[The growth of a bulb from a leaf is not at all unusual, the *Gloxinia*, *Sireptocarpus*, *Begonia*, to only mention a few, being easily increased from leaves. We have never heard of the Lily being increased in this way.]

Campanula arvensis.—Only those who have grown and flowered this unique Spanish Bellflower with some measure of success can form an adequate idea of its beauty and worth. Four inches or so high, and at its best in July, when covered with a profusion of its violet-blue or purplish flowers, it is quite one of the gems of a race which owes much to the miniature or alpine section of the genus. In flower character it may not inaptly be referred to a larger, freer-flowering, and more vigorously-inclined *C. Waldsteiniana*, to which must be added its more intense violet-blue colour. The leaf character, too, is quite distinct, green in that under notice, and with basal leaves varying from roundish cordate to almost Ivy-leaf form. Those of the other kind named are longer and of a glaucous tone, the plant smaller in all its parts. Of its perfect hardiness I am not yet quite sure, a goodly plant succumbing last year rather suddenly, probably, however, from some cause other than cold. Rich soils doubtless would be opposed to success, and moraine treatment, or poor, stony and gravelly soils, in which such as *C. cenisia* delights to ramble, would suit it better. It has also been called *C. acutangula*.—E. H. JENKINS.

VEGETABLES.

WINTER CUCUMBERS.

THESE are not in such demand now as was at one time the case, but where necessary to grow them the matter should now receive consideration. A house partly sunk in the ground, provided it is well heated, answers better for the purpose than one standing entirely above ground, as there is a much less loss of heat in cold weather, while structures of this description can be conveniently covered at night either with mats or canvas for the conservation of heat and economising of fuel. Before the plants are taken in, the house should be thoroughly cleaned, and if there is an old fermenting bed of leaves this should be cleaned out beforehand, as the space so occupied will be required for the making up of a new one when leaves become available unless a sufficient quantity left over from last year is in reserve. The leaves are, of course, to supplement and not to supply bottom-heat entirely, as a good quantity of hot-water piping laid in a brick chamber should be in existence beneath the bed. Before the new bed is made up the brickwork should be thoroughly limewashed.

Winter Cucumbers succeed best when grown in large pots. These should have their rims on a level with the surface of the bed, and to prevent them moving out of position it is best to stand them either on loose bricks laid one above the other or on inverted flower-pots before the bed is made up. Grown in this way the roots of the plants are well under control, and in due course, when the pots are full to the rim with compost, they can then be encouraged to root over the sides if suitable compost is placed above the rims and around the pots on the surface of the bed. If the house is not at liberty no time should be lost in getting the requisite number of plants of an approved free-cropping variety raised. Set out in good time, they will then bear in late autumn and throughout the winter, or until the January-raised plants come into bearing.

G. P. K.

NOTES AND REPLIES.

Peas failing.—I shall be glad if you can tell me what has made my Peas go off like this. They came up beautifully green and looked as though they were going to be a good crop. But they soon went yellow and died from the roots upwards during the damp weather we have had, the Peas becoming shrivelled before they were full. The gardener thinks there is some disease near the roots, and I shall be glad to know what may have caused it.—EVERS.

[The plants submitted have succumbed to an attack of the Pea blight (*Brachypisum pisi*). The only thing we can suggest in the way of a preventive is to dress the ground in future where Peas are to be grown with a soil disinfectant, of which several are advertised from time to time in our columns. If the attack could have been caught in its initial stage spraying with Bordeaux mixture would in all probability have killed or prevented its further development. This is a soil fungus of which but little is yet known.]

Thrips on Peas.—A row of Prince of Wales Pea, which is well above the normal height, looks quite healthy and has cropped abundantly. A good many of the pods are affected as enclosed, which appears to prevent them filling properly. My Peas this year have had no manure except a dusting of superphosphate at sowing-time, and never looked better. What is the cause and cure?—BENJILL.

[The Pea-pods are affected with thrips, a destructive pest which extracts the juices from the pods, which, in turn, prevents the Peas from developing. Unless

taken in hand directly the insects put in an appearance, remedies are of little or no avail. If the attack is not very general you may possibly save part of the crop by syringing the plants and pods at once with Quassia extract. This must be repeated daily until there are no further signs of the insects present.]

Planting vegetables in August.—Will you kindly tell me if it is too late to do anything with a kitchen garden the middle of August? I move into a new house then, and would like to know what vegetables I could put in.—**PRIMROSE.**

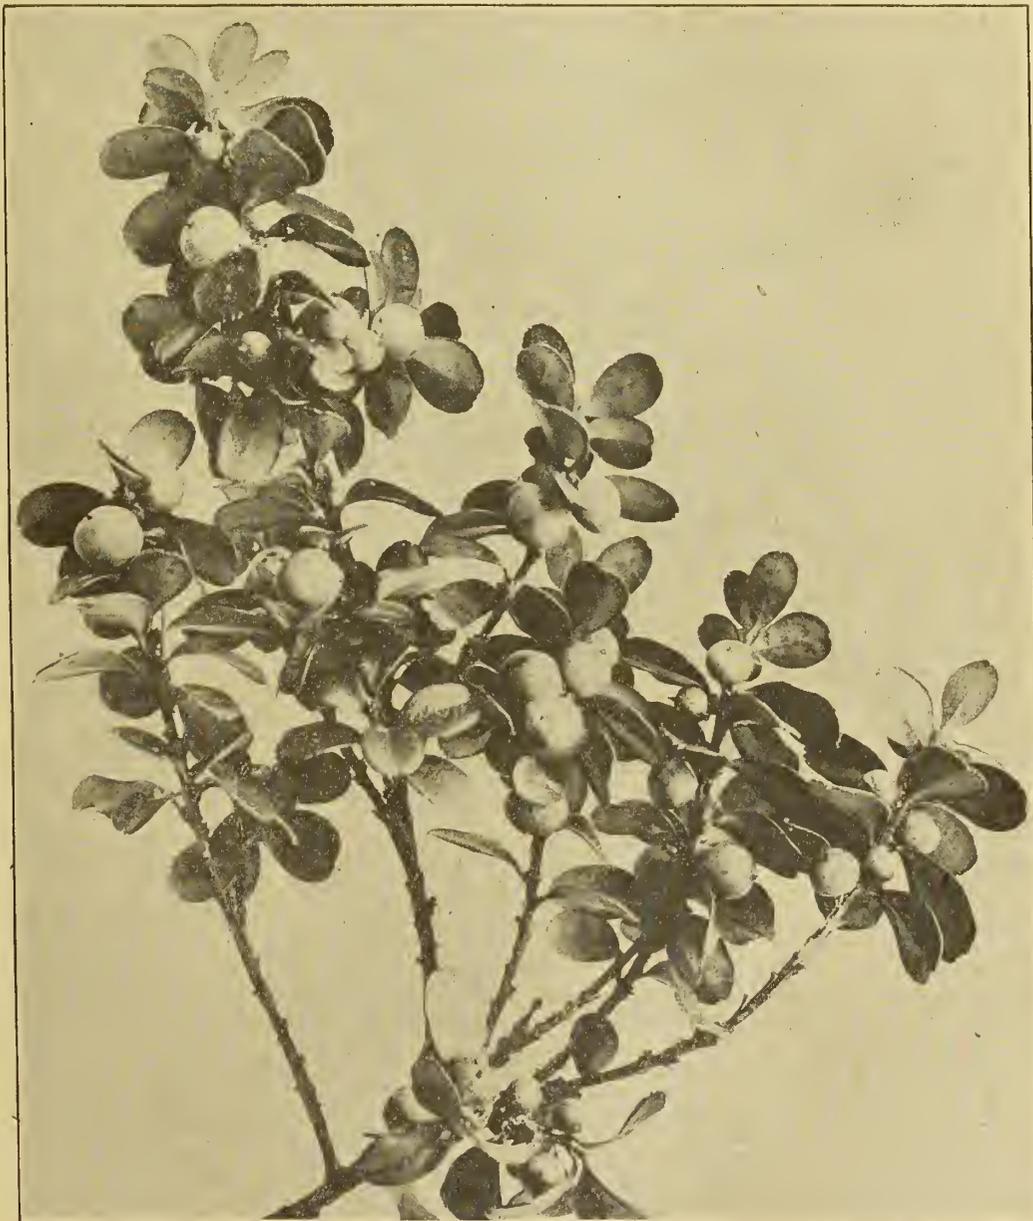

[It is not yet too late to plant your gar-

Mammoth, Penzance, Vanguard, Spring White, Leamington, Reading Giant, Safeguard, Late Queen, Model, and Latest of All. A selection from these will give you a regular supply up till June. The useful and hardy Sprouting Broccoli should be included, and do not omit to plant three or four different kinds of Kale, which are hardy and furnish a very wholesome article of diet from January till April. You would also be well advised in planting a good number of Cabbage plants of a suitable variety for spring cutting, such as Early April or Flower of Spring. These should be set out as soon as procurable on

TREES AND SHRUBS.

MYRSINE AFRICANA.

This interesting evergreen shrub is widely distributed in the higher regions of East Africa, in South Africa, the Himalaya, China, and other countries, but it is not generally hardy in the British Isles, although there are many places where it may be expected to give good results. It is quite at home in Mr. Messel's famous garden of rare plants at Nymans, Sussex, where it both grows and fruits well. Never growing very tall, it may be found

Myrsine africana in fruit. Nymans.

den with vegetables. No doubt you can yet obtain plants of Autumn Giant and Walcheren Cauliflowers, Autumn Protecting and Michaelmas White Broccolis, which will carry through to the end of the year. Then of the Cabbage tribe there are Cabbages of varieties such as Nonpareil, Enfield Market, and London Rosette Colewort. The last can be planted from 12 inches to 15 inches apart each way. Savoys must not be omitted. Of these there are Earliest of All, Drumhead, and the late variety of the latter. Of Broccoli for winter and spring supply varieties are numerous, reliable kinds being Winter

a well-manured and sheltered plot of ground 15 inches to 18 inches apart each way.]

Asparagus.—As Peas are now plentiful, cutting must cease for the season. Attention must, however, still be directed to the keeping of the beds clear of weeds and affording stimulants at intervals to ensure good results in future.

Tomatoes in the open are very late, but the crop has greatly improved since the advent of fine weather, especially in the case of those on south walls and buildings. Remove all surplus growth that the fruit may be exposed as much as possible.

under a foot high or it may exceed 3 feet in height, with a rather dense system of thin, twiggy branches covered with small oval leaves. The green and inconspicuous flowers are borne in the axils of the leaves, male and female blossoms appearing on different plants. The female flowers are followed by small berries, which are purplish in colour when ripe and very attractive, reminding one somewhat of small berries of *Pernettya mucronata*. The neat habit of this shrub makes it a suitable subject for the rock garden, where it should be given a sunny position in light loamy soil containing a

little peat. In places where it cannot be grown in the open it will probably prove a success if planted at the foot of a low wall with a south or west aspect. D.

THE SUMMER AND AUTUMN-FLOWERING HEATHS.

Few more beautiful sights can be imagined than wide, Heath-clad hills and moorlands from July onwards to the end of September. Although wild, Heaths may be brought into the garden, where they will continue in good condition for many years, giving little trouble and producing a lavish display of flowers each year.

Planting in formal-shaped beds should be avoided, and if an area of ground in a semi-wild part of the garden or park can be given up to them so much the better. They need not be isolated from other vegetation, but their associates should be such as will harmonise with them and their surroundings. Patches of French Gorse (*Ulex Gallii*) are very effective when interspersed with Heather and Ling, and the results of such combinations are well seen in the southern counties, more particularly around Bournemouth, where the Gorse forms compact, tussock-like patches, perfect masses of gold, amongst the Heather. The Bilberries are also good associates, as are also trees of such species as common Birch, Holly, and Scots Pine, arranged in irregularly-shaped clumps with occasionally an isolated specimen. Here and there, on the outskirts of the Heaths, patches of Wild Thyme may well be allowed to grow, whilst masses of the dwarf Scotch Rose are also in keeping. Pure garden plants, however, such as ornamental-foliaged trees and variegated-leaved Hollies, must be avoided, for they are quite out of place amongst natural surroundings and native plants.

Heaths are not difficult to cultivate provided they are given soil moderately free from lime. They are popularly thought to require peaty soil, but peat is not essential. Very good results are obtained by removing the coarse herbage from the ground to be planted, then spreading over the surface a layer 3 inches deep of decayed leaves or peat, afterwards digging the ground over one spit deep. Light loam is better than soil of a heavier nature. Plants can be raised from seeds, cuttings, or layers. The layers usually take two years to root, branches of old plants being buried in fine soil and kept in place by means of stones. Cuttings are taken during July and August and inserted in pots of sandy peat placed in a cold frame or in firm soil under a hand-light out-of-doors. Seeds are best sown indoors in February. After Heaths have bloomed it is a good plan to go over them and remove the old flower-heads, this improving their appearance and keeping them compact.

ERICA CINEREA is the commonest Heath in the British Isles. Under normal conditions it grows from 6 inches to more than a foot in height, and bears its reddish-purple flowers freely over a period of quite three months. Under cultivation variations have occurred in habit and colour of flowers. Some distinct forms have been given varietal names, *alba*, *rosea*, *atropurpurea*, *coccinea*, and *rubra* being very beautiful.

E. CILIATA, though less conspicuous than the last named, is abundant in some places. It forms very long, slender branches, lying close to the ground, from which erect flowering shoots spring. The flowers are rosy-red, rather large as hardy Heath flowers go, and borne in racemes for at least three months. The

variety *Maweana* is a great improvement on the type. It is of erect habit, with shoots each 9 inches to 12 inches long, bearing terminal heads of large red flowers from July to November.

E. TETRALIX (the cross-leaved Heath) is found almost throughout the country. It grows from 9 inches to 12 inches high and bears terminal heads of rich rose flowers. In one variety the flowers are white and in another pink. *E. Watsoni* and *E. Mackayi* are considered to be hybrids between this species and *E. ciliaris*. Both bear reddish flowers.

E. STRICTA is the tallest-growing of the summer and autumn-flowering Heaths. Under the most suitable conditions it may grow 8 feet high, though it is more familiar as a bush 3 feet to 4 feet high. The branches are erect and wiry, the flowers rose, and borne in terminal heads in July and August. A native of S.W. Europe, etc., it is hardier than other species from that region, and grows well in Derbyshire at an elevation of 1,000 feet or more.

E. VAGANS is better known as the Cornish Heath. Of vigorous habit, it forms a spreading bush 1½ feet high, bearing long, cylindrical racemes of pale pink or white flowers, according to variety, from August to October. It is common in south-west Cornwall, where it covers many acres. The variety *alba* has white flowers, whilst *rubra* and *grandiflora*, two excellent varieties, bear red and pinkish-purple flowers respectively.

E. MULTIFLORA, a native of S. Europe, is closely related to *E. vagans*. The rose-coloured flowers are borne freely from July to October.

CALLUNA VULGARIS, the common Ling, is usually associated with *Erica cinerea* in a state of Nature, and may occur in a variety of conditions, from a dwarf, Moss-like plant scarcely 1 inch high, to a tall, spreading bush 3 feet in height. It is easily distinguished from *Ericas* by the arrangement of the leaves, which give the stems an angled appearance. The pinkish-purple flowers are produced freely from July to September, August being the best time. As they are very productive of honey, bee-hives are often carried out to areas where the plant is common. There are numerous varieties with colours varying considerably in shade. *Alporti*, *rubra*, and *coccinea* are three of the best reds; good whites are *alba*, *alba Serlei*, and *Hammondii*; *euprea* and *aurea* have copper-coloured and golden leaves respectively; *argentea* has silvery leaves, and *minima*, *Foxi*, and *pygmaea* are of dwarf, compact habit. The branches of the tall-growing forms are often used for thatch for summer-houses, fruit-rooms, etc., and are excellent for the purpose.

DABECIA POLIFOLIA, called St. Dabec's Heath and the Connemara Heath, is another very useful relative of the ordinary Heaths. Found wild in Ireland and Western Europe, it forms a spreading bush 1 foot to 2 feet high, and bears erect racemes of large, urn-shaped flowers, which in the type are reddish-purple. There are also white and bicolor forms. Flowering commences during late May and continues through summer, but the most brilliant display is usually reserved for September. It is an excellent plant to include in the Heath garden, for it is at the same time attractive, and few shrubs have a longer period of beauty. D.

Zelkova serrata.—*Zelkova serrata*, or, as it is more generally known, *Z. keaki*, *Keaki* being the Japanese name for this tree, is one of the important trees of Japan. Although no longer very common or of a large size in the Japanese forests, it is

one of the largest of Japanese trees, for specimens 100 feet high, with trunks from 8 feet to 10 feet in diameter, are not uncommon in temple gardens and by village roadsides. The wood is more valued by the Japanese than that of any other tree; it is tough, elastic, and durable both in the ground and when exposed to the air, and is considered the best building material in the Empire. *Keaki*, however, has now become so scarce that it is not used for building except in temples in which the large, round, light brown, polished columns which support the roof are always made of this wood; it is universally used in the manufacture of *jinrikishas*, and it is still much employed in cabinet-making and turnery.

PLANTS AND FLOWERS.

INDOOR PLANTS.

THE HONEY PLANT.

(*HOYA CARNOSEA*.)

Would you please name the enclosed specimen and also tell me what is the best compost to use for growing same. Does it require to be fed during growth? If so, what kind of manure should I use? How should I strike cuttings of same, and what kind of compost? Please give cultural hints.—LANCASHIRE LAD.

[This is the name of the plant flowers of which you send. The best soil for this plant is peat with a small proportion only of yellow loam (about one-sixth). The peat should be full of fibre, so also should the loam, the finer or dusty particles in both instances being cast aside, for this plant does not thrive for any length of time in a close or retentive soil. To the peat and loam should be added some charcoal broken up to about the size of nuts, or in lieu thereof some clean, broken potsherds would be a good substitute, the object in either case being to aid in keeping the soil porous. Silver sand also should be freely added. In potting take particular care to pot firmly, as by so doing the soil will remain much longer in a condition favourable to healthy root-action. For a time after potting some considerable care should be taken in watering so as not to sour the new soil. At no time is *Hoya carnosa* a moisture-loving plant as compared with the average run of plants. Before it is watered it should be seen that the soil is fairly on the dry side. The extreme of drought should, of course, be avoided. The leaves should not at any time become soft or flaccid. Rather more water will be required when new growth is being made both at the root and in the atmosphere, with an occasional dose of weak liquid manure. A sunny, warm position from the spring onwards will do much to encourage flowering. As young growths proceed do not tie the shoots to the older wood, but allow them either to trail about or train them upwards on small strings. In potting, be careful to use clean or new pots, also drain the pots liberally. If it be practicable we should advise that your plants be planted out, using the same soil as in potting, only in a considerably rougher state. Under this treatment the plant would, if favourably circumstanced, grow more freely, and in all probability flower sooner if not eventually so profusely. A deep border would not be needed, but this and many other plants enjoy an extended root-run. *Hoya carnosa* is a very good plant for training on a wall; grown thus, if the wall be a little damp, it will, Ivy-like, root into the wall. It has a tendency even to throw out these roots under pot culture. When the flower-trusses eventually appear do not cut them, for the same trusses will go on

flowering continuously for several years at least once, and often twice, the same season; thus it will be seen that cutting the trusses robs the plant of much of its beauty. It is easily increased from cuttings inserted in any open soil and plunged in a moist heat.]

NOTES AND REPLIES.

Hydrangeas losing their leaves.—Kindly tell me why my Hydrangeas in pots all lose their leaves? They turn yellow and drop off.—MRS. A. LONGFIELD.

[You say nothing as to the treatment your Hydrangeas have received, but we have little doubt that starvation is the root of the trouble. It may be from the pots being crammed with roots or from want of water, perhaps the two combined. Again, if the plants have been grown in a somewhat close and shaded structure and from that have been turned out where fully exposed to air and sunshine many of the leaves may, from the altered conditions, turn yellow and drop. In the case

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

SAXIFRAGA COCHLEARIS MAJOR.

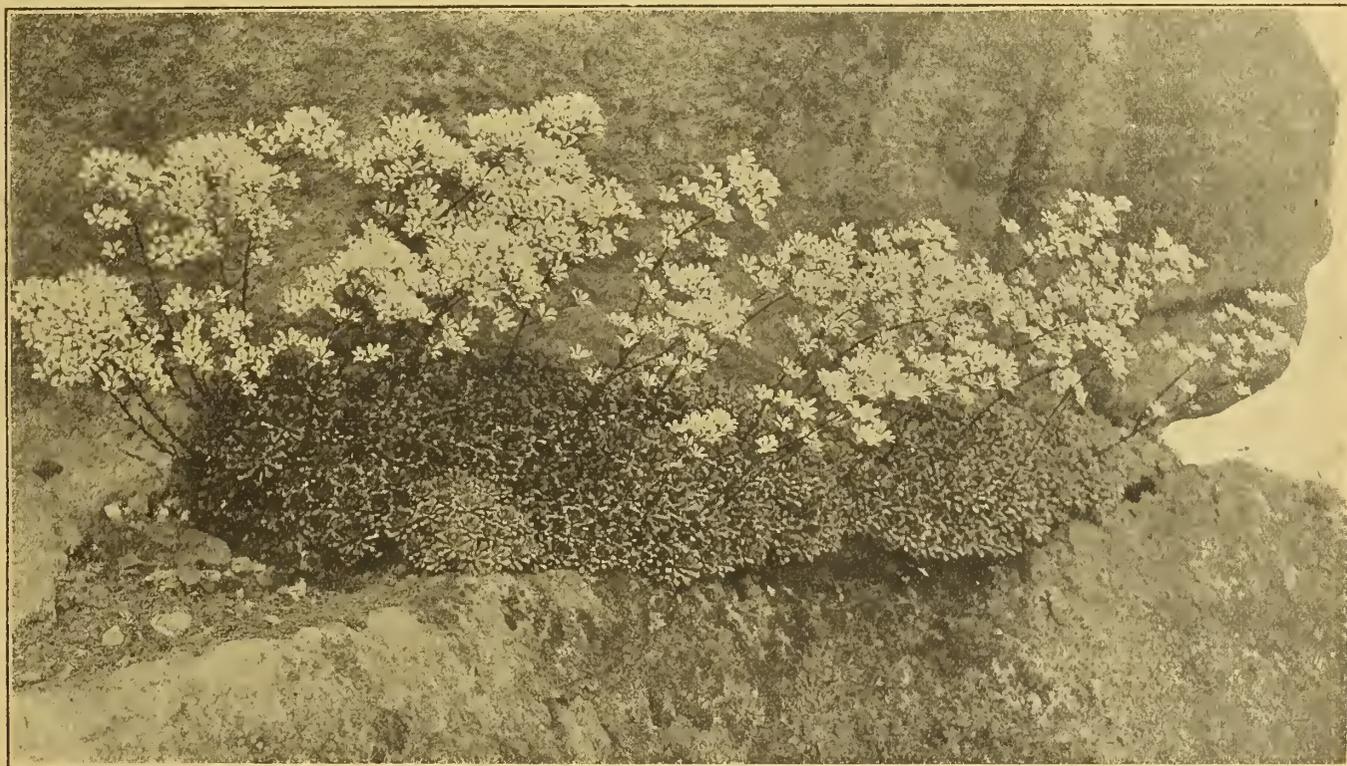

There is a nobility about this Saxifraga when in flower that distinguishes it from the majority of dwarf alpine plants. From a rosette not much bigger than half-a-crown is thrown up a foot high densely-branched flower-spike with about 100 pure white blossoms. The varietal term major is frequently applied without much reason, but in this case the type pales into insignificance by the side of the larger form. The accompanying illustration very faithfully depicts this fine Saxifrage and shows its decorative value when massed. For some years I grew the type under the name of major, and it strikes me that my experience is no uncommon one. I fancy that the majority of alpine plant growers are not aware of the existence of this major form, and as I got my plants in the first instance from a noted firm it is evi-

into which it can root and renew its vigour. After blooming the flower-heads should be sheared off at once to keep it in good health. There is a pretty white variety which, however, is not so vigorous as the type, and the foliage is of a lighter green. It is a precious plant even when out of flower for its beautiful carpet of tiny green leaves, which are pleasantly fragrant.

N. L.

THE ROCK NAVEI-WORT.
(OMPHALODES LUCILLE.)

This exquisite alpine has always ranked high among rock garden subjects, and one whose beauty must be seen to be realised, since no word picture could adequately portray its charm. Indispensable as it is to every good rock garden, it requires to be grown with the greatest care, keeping an incessant watch for slugs, which are almost sure to find it out. Just now it is in good condition in two opposite positions at Kew, one group receiving the morning sun the other the afternoon sun with

Saxifraga cochlearis major.

of Hydrangeas, if the pots are well furnished with roots an occasional dose of liquid manure or some other stimulant will be beneficial. As Hydrangeas are so easily grown your plants must have been sadly neglected in some way or other, but to what cause their ill-health can be assigned a personal inspection of the plants is absolutely necessary in order to give a positive opinion.]

Repotting.—The present is a very good time to repot Dracenas, Aspidistras, and Palms. Except, however, in the case of smaller specimens, repotting is not absolutely essential every year for the welfare of these plants. When it is needed there should not now be further delay, for with the advancing season root-action diminishes and the soil is apt to turn sour before they take possession. For potting Palms, if a good dark loam is available peat can be dispensed with. A little leaf-mould and sufficient sharp sand are necessary. Let the drainage be thorough, and pot firmly. Care is needful in watering, too much moisture leading to the collapse of the plant, while insufficient supply leads to the tips of the leaves turning brown and unsightly.

dent that some trade growers do not know it. The variety minor is very much smaller, not much bigger than cristata. It is a dainty little thing, but has not the stamina of the typical and major forms.

J. CORNHILL.

THYMUS SERPYLLUM.

This lovely native species is making the rock garden bright just now. The form usually grown is *T. Serpyllum coccineus*, a bright crimson, but the pink blossoms of the wild type are almost as nice, and both forms flower so profusely as to practically hide the foliage. It is one of the first rock plants I had, and I think it is still one of my favourites. It is of the easiest culture and will grow anywhere, either in sun or partial shade, provided the soil is light and fairly dry. It prefers soil of a calcareous nature, but is not at all particular in this respect. It is of rambling habit and likes to root as it goes along, hence it is not so suitable for hanging over a rock as for running along a ledge or down a wall which has plenty of crevices

shade at other times. As the plants of both groups appear equally happy, position might be regarded as not counting for much, though I look upon some measure of protective shade—as opposed to full exposure—during a part of the day as desirable. As to soil, I have usually had the best success from growing it in about equal parts of loam and peat, with fully a third of finely-broken brick and some sand intermixed. In short, a sparse-rooting subject always, perfect drainage appears essential.

Doubtless many during the last few years have given this unique subject moraine treatment, and the assured moisture during growth, with complete drainage at other times of such treatment, while going far to please it, should also assist to keep the slug at bay. Forty or so years ago the late Mr. James Atkins grew the plant to perfection in a small rockery at Painswick, the plant running about with considerable freedom in a rather low-placed position, which I also remember was mulched with slate chippings.

The soil was loam mingled with the magnesian limestone of the district, which suited many plants well. Given healthy, well-established specimens, it is not difficult to grow, though it is not one which the cultivator can do just what he pleases with. Disliking manure, which would appear altogether too gross for beauty so refined, it is fastidious also in the matter of moving and dividing established examples. Late in the year—September or after—is almost always fatal to success, and division, difficult at all times, and attended with uncertain results, should only be attempted in spring with the on-coming growth. Cuttings secured with a heel about the same period may also be rooted, though they require much care. Best of all ways of increase is by seeds, though a certain percentage of the seedlings, losing the soft, glaucous grey which characterises the original, appear with leaves of a pale-green tint. At flower time the soft grey, glaucous leaves, sky-blue flowers, and pinky buds form a pretty contrast. The "Dictionary of Gardening" gives 1873 as the date of its introduction from Asia Minor, etc. In that or the previous year, however, I saved a quantity of seeds from an established plant, hence I imagine a slight error exists.

E. H. JENKINS.

HYPERICUMS FOR THE ROCK GARDEN.

THESE are particularly welcome because they bloom in August, when, except for Campanulas and a few other species, the rock garden is getting bare of flowers. They are generally of very neat growth and seem for the most part to like a dry and sunny position. *H. Coris* is one of the neatest, making a pretty little miniature bush with tiny Heath-like foliage, crowded with little yellow stars of blossom. It is very happy with me in an exposed position in gritty soil. *H. polyphyllum* is a much more spreading plant, with long, almost prostrate, stems and large yellow flowers, with the usual big bunch of stamens in the middle. It succeeds in similar conditions to those that suit *H. Coris*. So does *H. olympicum*, which is somewhat smaller in flower and less spreading in growth, and with more glaucous foliage. Both this species and *H. polyphyllum* are readily propagated by layers or cuttings. *H. Coris* also strikes easily from cuttings. *H. reptans* is one of the choicest species, and this likes a partially shaded position where it can trail over rocks. Its flowers are more solid-looking than in the others, and remind one of a miniature *H. patulum*, as the flowers of *H. polyphyllum* suggest a very small edition of those of *H. calycinum*. *H. humifusum*, a native of this country, is a neat little trailer with small yellow flowers, and other good species are *H. repens*, *H. fragile*, and *H. cronulatum*. All can be propagated from cuttings.

H. Moserianum is a much bigger thing; in fact quite a shrub, but dwarf. It has very handsome, deep yellow flowers of good substance, and looks very well in the bolder parts of the rock garden. It seems a little tender if planted on the flat in ordinary loam, but grows very well with me on the lower part of a big retaining wall in dry, sandy soil, and is very easily kept within bounds by judicious cutting back in the spring. It is a hybrid between *Hypericum calycinum* and *Hypericum patulum*, and the flowers are almost as large as those of the former species, but of a deeper yellow and of a more solid texture. It flowers very freely and is quite one of the handsomest of the larger species.

N. L.

GARDEN FOOD.

THE TOMATO.

WE can remember the time when the Tomato was little known or liked, and yet to-day it is admitted to be one of our most useful and acceptable fruits of the sub-acid kind. Its peculiar nature makes it readily adapted for use, raw or cooked, and it is treated by some cooks as if it were a vegetable and by others as if it were a fruit. The Tomato is, in warm countries, best eaten raw, being useful either as a food or thirst-quencher. Eaten with brown bread and butter it makes an excellent form of sandwich. As a blood cleanser the Tomato, in our opinion, has no superior. It is purifying to a degree and has a tonic action on the liver that is most gratifying to those troubled at times with that organ. We have often thought, as we have read of places where Society meets for certain fashionable cures, that a Tomato cure, to be carried out at one's own home when the fruit is at its best, would be worth much more than some of the vaunted places of resort either in this country or on the Continent.

For those who prefer the Tomato cooked there is an abundance of forms available. As a salad in warm countries its use is frequent, as in America in summer. This vegetable is now in popular use in our country, judging by the excellent supplies of it in markets everywhere. The prejudice against it has died out to a great extent, and its excellent uses are acknowledged everywhere. With the Italian and Spanish cooks it is, of course, a most important aid, and therefore we consider it from that point of view, but it is even more important to consider its uses in the uncooked state. In all hot countries it is, perhaps, the greatest aid to the making of salads which people have, and its use in that way ought to be encouraged.

— The Tomato is easily cultivated. All who possess a garden with a moderate amount of glass can grow it successfully through the summer and autumn months, and in many localities it is possible to grow it satisfactorily in favourable seasons entirely in the open. However well Tomatoes may be grown in the open they always lack that high finish which they attain under glass, and without an average amount of sunshine it is certain that the work will be doomed to partial failure.

CULTURE UNDER GLASS.—Seeds should be sown thinly in well-drained pots or pans filled with a mixture of equal parts of good fibrous loam and leaf-soil, adding sufficient sand to ensure porosity. If the soil is in a medium state of moisture water will not be required before the seeds germinate. When it is needed, immerse the pots in a vessel of tepid water and let the moisture soak the soil from the crocks to the surface. Place the receptacles in a shady corner of a warm house. As soon as the seedlings appear place as near to the glass as convenient, and allow all the light and air possible to reach them. As soon as the seedlings are large enough to handle transplant them 4 inches apart into shallow boxes, afterwards potting them singly into 3-inch pots, using a compost of loam two parts, leaf-soil one part, and old Mushroom-manure and sand one part. Repot into larger pots as soon as necessary. A moderate temperature and a dry atmosphere suit the plants best. A close, moist atmosphere is conducive to disease, and plants subjected to such do not fruit satisfactorily. One of the chief causes of failure (especially among amateurs) is

finally placing the plants in too rich a soil and allowing them too much root-run. I much prefer growing Tomatoes in either 10-inch pots or suitable boxes to planting them out in open borders, as by so doing the growths are not so strong and the fruits begin to set much earlier and near the base of the plants. The soil for the final potting should consist principally of good, sweet, fibrous loam, to which should be added a little manure from a spent Mushroom bed, wood-ashes, and coarse sand or road grit. The pots or boxes should be well drained and sufficient fibre placed over the crocks to prevent the soil becoming mixed with them. When potting, make the soil very firm. Give a thorough watering after about the third day, and where possible the growths should be trained up the front of the structures on wires about 9 inches from the glass. Never allow any undue forcing, but endeavour to promote a sturdy, short-jointed growth. Give air freely both top and bottom when the weather is favourable, and a little ventilation should always be kept on the top through the night. Keep the plants to one main stem, and regularly remove all side shoots as soon as they appear. When the plants begin to flower give them a gentle tap during the day to distribute the pollen. Immediately the fruits swell, a moderate amount of feeding may be given.

OPEN AIR CULTURE.—The best position to grow the plants is against a south wall or a close-boarded fence. A west position is the next best. Failing this, choose a south border or the most sunny position available. The plants must have been sown and nursed along under glass, and good, strong specimens in at least 6-inch pots be ready for planting out by the end of May. Suitable varieties must be selected and the plants kept to one main stem, exposing both the wood and fruit to the sun and light as much as possible. Until a good crop of fruit is assured feeding must be withheld, after which mulch with good stable-manure, and keep the plants well supplied with moisture at the roots during dry weather. In late autumn it is often necessary to cut the fruit when quite green and ripen it in a warm place. Though these lack the flavour and high finish of those which are in a more advanced stage before cutting, they will be useful for cooking, sauce-making, etc.

VARIETIES are almost endless at the present day so far as names go, but many of them are much alike, being selections in many cases from well-known varieties. Nevertheless, a few sorts are not only quite distinct, but stand out prominently as among the best. Carter's Sunrise, I consider, takes first place as a variety for cultivation under glass or in the open. I have grown this under many and varied conditions and at all seasons of the year, and have never known it fail. It has everything to recommend it, being a very free setter even in the worst of weather, produces its trusses freely, of beautiful shape and colour, medium size, and of the highest quality. Other first-class and distinct varieties I have grown successfully include:—Under glass: Duke of York, Princess of Wales, Satisfaction, Best of All, Money-maker, Polegate, Ailsa Craig, and Winter Beauty. In the open: Sutton's Earliest of All, Magnum Bonum, Sutton's Mainerop, Abundance, and Sutton's Open Air, large fruits, somewhat corrugated, but of good flavour and one of the best for cooking.

F. W. G.

[In an early issue we hope to give some approved recipes for cooking the Tomato.—Ed.]

OUTDOOR PLANTS.

BROWN'S LILY.

We have known this Lily for many years, but never saw it so well grown as in the group shown at Hillbrook Place. The bulbs have been in five or six years and the bed they were planted in was not prepared in any way beyond trenched of the natural chalky soil. One curious thing about the bulbs was that in 1914 they flowered very well, while in 1915 very few came up and there were hardly any flowers, so much so that it was thought mice or disease had got at the bulbs. Then again this year they are excellent! This tends to prove that Lilies sometimes lie dormant for a year after prolific flowering. Perhaps the bulb of *L. Browni* dies

out very conspicuously against the ivory-white petals. *L. Browni* is, especially when dormant, very impatient of an excess of moisture, as the scales of the bulb are liable to decay just at their base; and sometimes the bulb, which, at a casual glance, appears to be sound enough, will fall to pieces on being handled.

Though by no means a rare Lily, it must be regarded among the more uncommon kinds. The only Lily with which *L. Browni* can be confounded is *L. odorum*, known also as *L. japonicum*, and in auction catalogues during the winter frequently called *L. japonicum Colehesteri*. Though a good deal of confusion has existed between the two, the points of difference are so well marked that there is really no excuse for it, as, commencing with the bulbs, those of *L. odorum* are

the fact that the English Iris (*I. xiphioides*) prefers a rather wet and cold soil to a dry, warm one. In a moist position the leaves do not become yellow so soon as in a dry one, where they wither long before the flowers have reached the zenith of their beauty, and are, indeed, frequently quite yellow before the blooms expand.—Ess.

AMONG THE HARDY FLOWERS.

PERENNIAL LARKSPURS FROM SEEDS.—Most of the seedlings from a good strain are useful, and a few may be found of sufficient quality to be considered worthy of a special name. Delphiniums are easily raised, either by sowing the seeds in a pot or box in spring under glass or sowing in shallow drills in the open later in the season. I have even had good plants from

Group of Lilium Browni at Hillbrook Place, Iver, Bucks.

after flowering and offshoots flower the next year.

— This is a beautiful Lily. The flowers, which are large and massive in texture, are ivory-white within, but heavily tinged with chocolate on the exterior, especially if they are in a position fully exposed to the sun, as where heavily shaded the marking is less pronounced. The bulbs of this are very distinct from those of any other Lily, being narrow at the base, widening towards the centre, with a peculiarly flattened top, the entire bulb being tinged with reddish-brown. Its flowers have an agreeable perfume, which is not so powerful as in many other Lilies. The foliage is very dark green, while the stem, especially towards the base, and the leaf-stalks are tinged with purple. When the blossoms are fully expanded the dark-brownish anthers stand

whitish, and in shape more like those of the longiflorum section, that is, broader at the base than in *L. Browni*, while the centre is somewhat raised. In all stages the stems of this are green, the leaves much broader and thinner in texture, while they are throughout of a dull pale green, very different from those of *L. Browni*. The flowers, too, are somewhat shorter and rather more widely expanded at the mouth, while the exterior is much less deeply tinged than in *L. Browni*. It is somewhat difficult to understand the specific name of *odorum* being applied to this Lily, as so many other members of the genus are quite as fragrant.

English Irises.—These have been late this season, but they are flowering better than last year, when a period of drought checked their progress. This bears out

self-sown seeds, but it is not wise to trust to these.

INCARVILLEA DELAVAYI DYING OFF.—I wonder what is the reason that old plants of *Incarvillea Delavayi* die off in many cases after having been established for several years. Some growers tell me that the tuberous roots get too big and old, and that decay sets in. Others assert that it is frost which causes the death of the plants, as the crowns are too shallow and are destroyed by severe frosts. Still others assure me that insufficient drainage rots the tuberous roots. I have come to the conclusion that a rather light, dry, well-drained soil is the best, and that the plants ought to be deep enough planted, so that the crowns may be 3 inches or 4 inches beneath the surface. I have been doing this with advantage, and some of my plants are now of considerable age.

By the way, *Incarvillea Delavayi* comes easily from seeds, which are plentifully produced by my plants. The seeds can be sown in the open in spring or summer, but it is preferable, I think, to sow them in a frame.

THE NETTLE-LEAVED BELLFLOWER.—*Campanula Trachelium*, which I have seen named *C. urticifolia*, is not up to the high level of beauty of most of the other varieties. At one time, I am told, a double white and a double blue variety were largely grown. I have in my garden several single-flowered varieties, but these are being gradually banished. This Nettle-leaved Bellflower seeds very freely, so that if a plant is allowed to ripen seeds a crop of seedlings soon appears. I do not think *C. Trachelium* is worth keeping, as it is far inferior to many of the Bellflowers which grow to rather more than a foot high, its usual stature.

WHITE PINKS.—I have an idea that Her Majesty is one of the best as regards the non-splitting of the calyx. The old double White Pink is pretty and satisfactory in many ways, but the splitting of the calyx is a great defect. As an edging plant it has been very largely employed in old gardens, and there is nothing so fragrant among the Pinks as this old-fashioned flower. I grow Mrs. Sinkins still, but it, also, is a bad splitter, and some do not care for the greenish-tinge in the centre of the flower. I can forgive both these faults, and appreciate the handsome, fragrant blooms.

SINGLE PINKS FROM SEEDS.—I have been admiring a lot of single Pinks raised from *Dianthus plumarius*. Some of these seedlings are charming and the shades of colour and markings are very beautiful. I have white, pink, rose, and nearly crimson-flowered forms, with zones and spots of different shades on the flowers. Some with dark chocolate, deep maroon, or red zones are very beautiful and quite equal to some named varieties.

AN AMATEUR OF HARDY FLOWERS.

CAMPANULA GLOMERATA DAHURICA.

THIS form of the clustered Bellflower is not only one of the best of its race, but it is also one of the showiest and hardiest of true herbaceous perennials. Quick and easy to grow in almost any class of soil, good in colour and free-flowering are among its many good points. Less than 2 feet high, producing leafy, sturdy stems surmounted by clusters of erect, bell-shaped flowers of a deep violet-purple tone, the plant is at once attractive when seen in flower. The flowering is long continued, the spikes also appear in profusion from a low, spreading tuft, which, if generously treated, will soon cover a ground area of 2 feet or more; indeed, were it so desired—and the plant is well worthy of it—a yard wide patch could readily be formed by pulling a few clumps into small pieces and replanting the latter a few inches asunder. No plant lends itself better to this particular treatment, and when, a year hence, the group reaches the flowering stage, it will be seen how amply repaid is the gardener for the trouble he has taken. Not only does the plant lend itself readily to this free increase, it is immeasurably benefited thereby, and the flowering proportionately increased and improved. Happily, the sturdy stems require no artificial support. March and the early portion of April are the best seasons for dealing with the plant as suggested above. Firm planting and a generous treatment—*i.e.*, deep digging and a free addition of decayed manure and leaf-soil—will not be in vain. There is a

white-flowered variety of the typical *C. glomerata*, and, if not quite so large in its individual blossoms as the subject of the present note, is still large enough and good enough to merit general cultivation.

NOTES AND REPLIES.

Phlox Aubrey Alder.—This is one of the new herbaceous Phloxes. It is the only variety, I believe, not in commerce that secured an Award of Merit at the Royal Horticultural Society's trial at Wisley last year. In that trial a great number of varieties, new and old, were included, and with good ordinary cultivation, such as might in any garden under normal conditions be meted out to them, some few naturally stood out well from the rest. That above-named was one of them. The colour is an intense brilliant salmon with almost crimson eye. It is of moderate height, 3½ feet or so, of good habit, and one which, apart from colour, may lay claim to distinctness by reason of its unusually dark stems.—E. H. J.

Nepeta Mussini.—All through June the garden has been brightened by the masses of deep lavender-blue flowers of this. It is seen at its best and flowers most freely when in a hot, dry position. I have it all about my garden here in London, but the best clumps are on top of a high retaining wall, where it makes a mass of lovely colour for weeks together. The greyish foliage is quite pretty, too, when the plant is out of bloom. It seems to appreciate a little lime in the soil.—N. L.

GARDEN PESTS AND FRIENDS.

WEEDS AND THEIR SUPPRESSION.

DAMAGE DONE BY WEEDS.—The most serious objections to weeds may be stated as follows:—(1) They absorb from the soil moisture and plant food which would otherwise go to nourish and increase the crop which is being cultivated. (2) They "crowd" the crop, restricting the amount of light, heat, and air necessary for healthy growth and for the proper assimilation of plant food. The effect is to hamper the growth of the plants during early life, especially in the case of crops of slow growth, while they prevent or retard ripening and drying, particularly in the case of Corn crops. The straw of cereals may be weakened and rendered liable to "lodge," thus making the work of cutting at harvest both difficult and expensive. (3) Weeds, especially such climbing kinds as Bindweed and Cleavers, hamper harvesting of Corn crops, both as regards cutting and drying. (4) Weeds interfere with, and render more expensive, proper and thorough cultivation, and the "singling" of root crops. (5) Weeds may harbour, or favour the development of, insect and fungus pests. (6) The value of samples of cereals is reduced by the presence of Cockle, Garlic, Cleavers, and Wild Vetch; the value of most farm seeds is lowered by the presence of the seeds of weeds; and the market value of Hay and other farm produce is similarly reduced by certain weeds or their seeds. (7) Some weeds—*e.g.*, Garlic—taint the milk of cows which eat them, whilst others—*e.g.*, Meadow Saffron and Water Hemlock—are poisonous to stock generally. (8) Other weeds (Dodder, Broomrape, Yellow Rattle) are parasitic or semi-parasitic, and directly feed upon the crops they infest. (9) The underground stems and roots of weeds may cause the stoppage of drains. It is impossible to obtain the best returns from the land when weeds are allowed to grow unchecked. Experiment has shown that on a properly weeded area of arable land the crop may be double that on an unweeded area.

MANNER OF DISTRIBUTION.—Before the suppression of weeds can be intelligently dealt with it is essential to have a clear conception of the manner in which weeds are spread broadcast amongst cultivated crops. The manner of distribution is very varied, but amongst the commoner processes are:—(a) Distribution by means of the wind. Many seeds, like those of the Poppy, are so small that they are readily scattered considerable distances from the parent plant. (b) Distribution by means of a special parachute-like apparatus, or other arrangement, of fluffy hairs and flattened wing-like projections, by which seeds, such as those of the Thistle, Dock, Groundsel, etc., are rendered buoyant, and easily carried about in a light breeze. (c) Distribution by means of farmyard manure. Screenings from threshing and winnowing machines, and sweepings from barns and hay-lofts, often find their way to the manure heap, while manure from cattle fed on inferior hay is also likely to contain weed-seeds. Many seeds of weeds may be uninjured by the heat of fermentation, and will in due course pass on to the fields. Some seeds may even germinate better after lying in the manure heap, or after passing through the stomach of an animal. Well-rotted farmyard manure will, however, contain fewer germinable weed-seeds than fresh manure, and is, therefore, less liable to introduce weeds. (d) The use of impure seed is a potent means of introducing weeds to a farm. The presence of 1 per cent. of Dock seed in a mixture of Grass and Clover seed means ten or more Dock seeds per square yard all over the field wherever such a sample is sown at the ordinary rate for leys. (e) Some weeds—*e.g.*, Creeping Thistle, Couch, Field Bindweed, Onion Couch—are spread by means of broken portions of the rootstock, which may be carried from field to field or farm to farm in a variety of ways.

METHODS OF SUPPRESSION.—Weeds may be annual, biennial, or perennial, and must be combated by somewhat different methods according to their habit of growth. It must be emphasised that, whatever methods are adopted, they must be promptly, vigorously, and faithfully carried out; systematic, well-timed effort is the foundation of success. (1) The most obvious means of suppressing weeds is to prevent them seeding. When it is recognised that an ordinary Charlock plant produces from 1,000 to 4,000 seeds, and a moderate-sized Poppy 10,000 to 15,000, and large plants 50,000 seeds, the force of the adage that "one year's seeding is seven years' weeding" is obvious. Further, as many weeds produce seeds which do not germinate uniformly, the mischief is greater than appears at first sight, for they may lie dormant in the soil and grow after several years. In destroying weeds of this type the frequent recurrence in the rotation of root and other crops which permit thorough cleaning is an advantage (see also 4, 9, 13). Seeding of weeds growing in hedgerows, on roadsides and waste places, and round farm buildings, should similarly be prevented. (2) Under no circumstances should imperfectly cleaned seed be either purchased or sown. Care should be exercised as to the disposal of refuse seeds from threshing, screenings, sweepings of hay-lofts, etc. Such refuse should be burnt. (3) Deep ploughing is sometimes resorted to with considerable success, many seeds rotting when deeply buried. Others, however, remain dormant under such conditions, without losing their vitality, and may subsequently be brought to the surface. Where practicable, shallow

cultivation and the preparation of a good tilth prior to the sowing of a crop will encourage the seeds to germinate, when they may be destroyed by further stirring of the soil. Such a method will help to clear the ground of many annual and biennial weeds, such as Poppy, Charlock, and some species of Thistle. (4) In view of the present shortage of manual labour, in districts where hand-hoeing is usually largely practised, Corn crops may usefully be drilled in rows wide enough apart to permit of horse-hoeing, say 8 inches to 9 inches apart. This is especially useful in the case of spring-sown Corn. (5) Where horse-hoeing cannot be practised, the wetter the climate, or the more the land is subject to the growth of annual weeds, the closer the drill coulters should be set. When weeds are plentiful it is advisable immediately after harvest to disc or lightly scarify the surface, with a view to encouraging the germination of annual weeds. These should afterwards

stored up in their rootstock and prevent storage of further supplies. Judicious cutting with spade, hoe, or scythe will destroy all weeds if the cutting is repeated often enough. Many weeds when cut near the ground send up new stems, and these are produced at the expense of food stored below ground in the previous season. The growth of these secondary stems weakens the plant as a whole, and if, when produced, they are immediately cut off and the process repeated, total destruction will be the result, no matter what the plant may be. The first cutting should be made early in the year, and as often after that, during the summer, as new shoots appear. If left too long the weeds may either seed, or again store up food in the roots in preparation for the next season's growth. One cutting in the case of perennials like Creeping Thistle, Field Bindweed, Couch, and Coltsfoot is quite valueless. (9) Fallowing, either bastard or bare, as a cleaning process, is largely

ing may so stimulate cultivated crops that many of the worst weeds will be crowded out, a fact which is of especial significance at the present time in connection with the growing of successive Corn crops. (12) Farmyard manure, believed to contain weed seeds in any quantity, should be allowed to rot well before application to the land. Many weed-seeds may be present when meadow hay and chaff (barren glumes) of Oats are fed to stock. (13) Weeds may often be suppressed or much reduced by the growth of dense, heavy "smother" crops which choke them out. On foul land such crops may be of much value before or after a well-hoed root crop. Suitable crops for the purpose are Vetches, or a mixture of Vetches, Peas, Oats, or Beans; Mustard, Rape, and Maize. The last-named is especially valuable, because it is not only thoroughly hoed, but casts a dense shade. It can, however, be grown only in the warmer southern counties. Where weeds are likely to be abundant it may prove a good plan to sow part of the root "break" with a Vetch mixture in autumn. This would not only "smother" out weeds, but reduce the labour bill for roots. (14) Close feeding with sheep will often check certain plants and prevent them seeding, e.g., Ragwort, Yellow Rattle, and Hardhead or Knapweed. (15) Finally, spraying crops with chemical substances, more especially with sulphate of copper (bluestone) and sulphate of iron, has been found exceedingly useful in destroying weeds. The destruction of Charlock in corn crops by spraying is dealt with in Leaflet No. 63. Solutions of the sulphates of copper and iron, however, may be employed against other weeds, some of which may be destroyed and others crippled. *Persicaria* or Red-shank and Spurrey may respectively be killed by spraying with 4 per cent. and 5 per cent. solutions of copper sulphate, while the following weeds are more or less crippled and seeding largely prevented by spraying with a 5 per cent. solution of copper sulphate, or a 15 per cent. solution of sulphate of iron:—Poppy, Corn Cockle, Black Bindweed, Dock, Groundsel, Dandelion, Perennial Sow Thistle, Cornflower, Thistles, and Coltsfoot.

LABOUR.—During the past year, no doubt largely owing to shortage of labour, weeds were unusually plentiful in many districts. The shortage in manual labour may largely be met in so far as the destruction of weeds is concerned by the employment of women and children, working when necessary in gangs in charge of one or two older and practised hands; and of temporary workers who may be in a position to do work of this kind for short periods. In regard to labour, more use should be made of the Local Labour Exchanges.—*Leaflet No. 112 of the Board of Agriculture and Fisheries.*

NOTES AND REPLIES.

Peas, insect on.—Will you kindly tell me what is wrong with the enclosed Pea pods? I have had a splendid and early crop, but so many of the pods have had their appearance spoiled by this marking and a kind of mould inside. I shall be very much obliged if you will kindly advise me as to future treatment and say what is wrong. Your paper is ever of great interest to me.—A. ROWAN.

[Your Peas have been attacked by an insect commonly known as Black Thrip. If the attack is allowed to develop, irreparable damage to the crop ensues. The great thing in dealing with this pest is to attack it in the initial stage, when, if the plants and pods are syringed daily with Quassia extract, the insects are quickly killed off and the crop saved.]

Flower of Lilium Browni. (See page 413.)

be ploughed down. (6) The eradication of perennials, such as Couch, Field Bindweed, and Creeping Thistle, needs careful and well-directed effort. These plants are propagated by underground runners bearing buds, and the object should be to remove the rootstocks as far as possible unbroken. This will usually be best accomplished by shallow ploughing followed by grubbing or cultivating, rolling and harrowing. The weeds should be collected and either be burnt or made into a compost with lime. Sometimes, however, as in fallowing, they may first be brought to the surface and left to the drying effects of wind and sun. (7) Hand-pulling, digging with fork or spade, and total removal of weeds are efficient means of destruction, but these methods are all expensive, and are only resorted to when other plans have failed or are inapplicable. In every case the weeds collected should be burnt. (8) Any perennial weeds may be cut down frequently to exhaust the supplies of food

practised with good results on the heavy classes of soils on which root crops are uncertain and expensive to produce. At present, however, bare fallowing should be reduced to a minimum, "smother" crops being introduced (see 13). (10) Rushes, Sedges, and Horsetails are indicative of a sour soil, which can be remedied by draining and liming. A dressing of lime is, more or less, a specific against Sorrel, Corn Marigold, Spurrey, and some other weeds. (11) The application of dung and artificial manures induces considerable changes in the character of the herbage on pastures and of the weeds on arable land. The application of 5 cwt. to 8 cwt. of basic slag per acre to pastures on stiff clay land often has a wonderful effect in encouraging Clovers and generally improving the herbage, while a mixture of superphosphate and sulphate of ammonia is often an effective means of reducing such weeds as Buttercups, Daisies, and Plantains. Suitable manur-

FRUIT.

GRAPES SCALDING AND SPLITTING.

The berries of all varieties are liable to be scalded just before they begin to colour, those of a few varieties splitting badly at the same stage. Madresfield Court is one of the sorts that split badly. If the treatment is good both the scalding and splitting of the berries can be reduced to a minimum, if not altogether avoided.

SCALDING.—Usually scalding occurs in the early morning. If the house has been closed through the night, directly the sun shines on the glass in the morning a lot of moisture condenses on the cold skin of the berries, and, a little later, if this moisture is not gradually dispersed, one side of the berry will be scalded, and sometimes many berries in a bunch will suffer. Rarely are berries thus scalded if the ventilators are opened early in the morning before the sun shines on the house. If the grower cannot make sure of thus opening them the best plan will be to open them nearly 2 inches wide at 10 o'clock at night, moisture not then condensing on the berries. Berries may be badly scalded if theinery is closed too early in the afternoon on a day when the sun is very hot. On such days it is much better to leave the ventilators open longer and gradually close them as the sun-heat lessens. The same atmospheric conditions that cause the scalding are conducive to the

SPLITTING of the berries. I have grown that superb variety Madresfield Court for many years and had berries split wholesale in the early days when I did not know how to treat it properly. But during the past twenty years I have not had much trouble from splitting. Allowing an extra growth of laterals, keeping the border drier, etc., will not prevent splitting if the house is kept closed in the morning and again in the afternoon when hot weather prevails. I have purposely kept the structure closed and watched the berries at the stage when colouring begins, and though not actually seeing the berries split, I have seen them whole one minute and in a split condition the next. To avoid splitting I always keep the soil in a regular state as regards moisture, and never entirely close the top ventilators night or day from the time the berries begin to take on the final swelling and colouring. I further cover the moist surface of the border with short litter or straw.

All Grapes, when colouring, should have plenty of air. I have removed squares of glass from ventilators opposite bunches of Madresfield Court and seen the bunches move to and fro in the breeze created on a very hot day, and the side of the bunches next to the opening, and facing north, was as black as Sloes when the other side was half coloured. BOURNE VALE.

Strawberry-beds.—Where Strawberries are grown on the three or four years system, which is the rule generally, a plot of ground must now be selected for the planting of the new bed. This should be well manured and thoroughly dug at once, which will allow ample time for it to settle down and be in excellent condition for planting early in August. In the meantime the requisite number of plants of the varieties favoured should be layered into small pots, and if done without further delay, so that the layers become well rooted and established by the end of the present, and planting out effected early in the succeeding month, a good crop of fine fruit results the first season. As to the utilisation of the ground which has been carrying the

Strawberries to be discarded, it can either be dug over and reserved for the planting of Cabbages for spring cutting, or after hoeing and cleaning the surface it may, without further preparation, be planted with maincrop and late varieties of Broccoli.—G. P. K.

NECTARINES AND PEACHES FAILING.

THE bearer will hand you two Nectarines. You will see that they are small and in very poor condition. Could you let me know the reason for the failure of these Nectarines? If you eat them, however, you will see that they do not taste at all badly. I have a Peach-house at Bromley, Kent, 20 feet long and about 9 feet wide. It has a wall at the back (north), and the front (facing south) is glass. It is ventilated on top and in front. I have a Nectarine and a Peach inside the house near the glass front (and not against the wall). Although the house is heated, I do not use heat, because I prefer the Peaches and Nectarines to ripen naturally, and usually the Nectarines are ripe by about July 14th, and the Peaches about the end of July. This year, however, no doubt owing to the cold, sunless summer, I have only just begun to gather the Nectarines, and I do not suppose I shall be able to gather any Peaches till towards the end of August. No rain, of course, gets into the house, but the gardener keeps the border watered at suitable intervals, using each time about two big tankfuls of water. He, of course, syringes the trees from time to time, but keeps the water clear of the fruit when it is near the ripening stage. After the fruit stones we put a top-dressing of cow-manure on the border. The border is about 9 feet deep, with cement foundation, and is composed of a mixture of loam, lime-rubble, charcoal, and $\frac{3}{4}$ -inch bones. There is a sump, which carries off any excess of water. I have had the Nectarine about fifteen years, and until three or four years ago it has always cropped splendidly and the fruit has ripened well, and it had a good appearance and flavour. For the last three or four years the fruit seems to have been going off, the tendency being:—(a) To diminish in number and size of the Nectarines. (b) To show a sort of rust on the skin on one side of the Nectarine (you will see the rust on one of the Nectarines herewith, though there is none on the other Nectarine). (c) No flavour to speak of. If you could give me an explanation of the deterioration I should feel much obliged. I am sure the gardener must be making some blunder. I might add that the Peach-tree has not been doing quite so well during the last three or four years as it used to do, though the falling off is nothing like so marked as in the case of the Nectarine.—NECTAR.

[The general condition of the Nectarines indicates that the tree is out of health, which is without doubt due to the roots being beyond the influence of air and warmth, or in other words through the border being of too great a depth. Instead of being 3 yards deep, 1 yard, including drainage material, would be an ample depth, and we fear that unless you take steps to remedy matters in this direction the condition of the tree will grow worse rather than improve. This means lifting the roots of the tree, which can be done with safety if undertaken just before it sheds its foliage in autumn, throwing out the soil to the required depth, viz., 3 feet 4 inches, and putting in a concrete floor or base 4 inches in thickness. When set, place 6 inches to 9 inches of drainage material in two grades, coarse and fine, all over it, and cover with whole furves Grass side down. On this place a layer of soil, spread out the roots at their various levels; cover with fine soil, making all very firm as the work proceeds. If the old compost is worth using again mix a modicum of new loam with it, but if it has become inert and worn out then use new material only. Have everything in readiness before lifting is commenced

with, so that the roots are out of the soil for as short a period as possible. Wet Moss placed in mats is an excellent material with which to enclose the roots as they are laid bare and liberated from the soil. It is also a good plan to shade the roof over the tree and to keep the foliage moistened with a syringe from the time lifting commences until the tree is replanted. The Peach tree alluded to is no doubt getting into the same condition, and would be best lifted at the same time as the Nectarine.]

NOTES AND REPLIES.

Fungus on Plums.—I send some Plums, most of which are going bad, as you will see. Gum exudes from many, and it is questionable whether, after removing those attacked, the remainder will reach maturity. It is unfortunate, as most of my other trees are very thinly cropped or have none at all.—SUSSEX DOWNS.

[The Plums have been attacked by the fungoid disease commonly known as the brown-rot fungus (*Monilia fructigena*). Your best course is to pick off all affected fruits and burn them. Then spray the tree three times at intervals of ten or twelve days with Bordeaux mixture. Next spring, some time before the buds expand, spray the tree with sulphate of iron, using $\frac{1}{4}$ lb. of the latter to every gallon of water required. After the tree has flowered and set its fruit, spray two or three times at fortnightly intervals with Bordeaux mixture at half or summer strength. The latter can be purchased ready for use from any dealer or maker of insecticides with instructions attached.]

Plum Coe's Golden Drop.—In a season when Plums are none too plentiful it is pleasing to notice that Coe's Golden Drop is bearing its usual heavy crop. Reputedly, in this district, a rather difficult Plum, I cannot recall a season during the past twenty years in which Coe's Golden Drop did not justify its inclusion in the collection, and amply repay the space upon the walls which the trees occupy. Ripening in late September and early October, the variety is specially useful, for even when the crops of Plums are heavy the most of the fruits are over before Golden Drop ripens. Of excellent flavour and handsome shape, being, in addition, a free-stone, this Plum is highly appreciated in the dessert. The red variety of the same Plum is equally useful, although, perhaps, hardly equal to the yellow sort in point of flavour.—W. McG., *Balmoe*.

Strawberries.—The plantations of these will be examined as soon as the fruit is gathered, and plants that have been upon the ground two or three years will be cleared off, and the soil prepared for late Broccoli or some other vegetable. Plantations intended to remain for another year must on no account be neglected, as the quality of the next season's crops depends greatly upon the way they are now managed. Having removed the nets, clear the plants of weeds, exhausted foliage, and runners. See also that the plants do not suffer from want of water, and, if possible, give necessary nourishment in the form of liberal applications of liquid-manure. This will encourage them to form strong crowns for next season's fruiting.

Morello Cherries.—These trees are trained very similar to the Peach. Shoots growing at right angles to the wall known as fore-right shoots—and others that are not required for fruiting next season should be cut clean away, for the Morello Cherry requires different treatment from the Sweet Cherry, which develops its fruit on spurs. A sufficient quantity of young wood should be trained in annually on Morello Cherries to furnish the fruiting wood of next season. Tie the growths in loosely and encourage a healthy, clean growth. The fruits should be protected from birds before they change colour.—G.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM AUGUST 9TH.—*Solanum jasminoides*, *Honeysuckles*, *Clematis* (in variety), *Magnolia grandiflora*, *Ceanothus* (in variety), *Buddleias* (in variety), *Carpenteria californica*, *Polygonum baldschuanicum*, *Olearia Haasti*, *Spiraea arifolia*, *S. THE WEEK'S WORK.—Seeds of many herbaceous perennials, alpine and rock plants have ripened, and these have been sown during the week. If these seeds are sown a few days after they are gathered, when quite ripe, they germinate much better than if kept for a time. A bed of light, sandy soil was made up in a cold frame, and the seeds sown thinly in drills 6 inches apart, covering them with finely sifted soil. Afterwards the seed-bed was watered carefully through a fine rose can, the lights placed in position and shaded until the seeds have germinated. Ventilation is afforded as soon as the seedlings appear, increasing the amount of air gradually to induce the plants to grow sturdy and strong. Some varieties of early-flowering *Chrysanthemums* have been slightly disbudded. This is necessary with some varieties where flowers of moderately good size are desired, but the disbudding should not be so severe as to spoil or even alter the character of the plant. Now that the weather is so hot and dry these plants require frequent liberal waterings. *Azaleas*, *Rhododendrons*, *Camelias*, and all similar plants are amongst the first to suffer from want of moisture at the roots. These have been thoroughly watered and heavily mulched with leaf-soil. Borders of *Belladonna Lilies* have been cleared of all weeds and leaves, and the surface-soil stirred, afterwards giving a thorough soaking of water, which will enable the flower-spikes to come all the stronger. *Violets* have made good progress during the last few weeks. All side shoots are removed as they appear, and the Dutch hoe frequently used between the plants. It is necessary to syringe them freely twice daily—morning and evening. Good dustings of soot are applied frequently as a means of keeping red-spider in check. Hardy bulbous plants, such as *Narcissi*, *Tulips*, *Scillas*, *Lencojums*, *Grape*

and *Feather Hyacinths*, as well as many others that increase freely, deteriorate if left too long undisturbed. Where lifting and re-planting are decided on the present is the most suitable time to carry out the work. Lift the clumps carefully, separate, and replant without delay. F. W. GALLOP.

Lilford Hall, Oundle, Northants.

SOUTHERN COUNTIES.

Strawberries.—The perpetual-fruiting varieties of which St. Antoine de Padone is a good type, should now be allowed to fruit, and the same care taken to protect the berries from being splashed with soil and from bird attacks as is meted out to other varieties. If necessary, water freely to assist the berries to swell to full size. Plants which were forced and afterwards set out should be kept clear of runners and well watered at the roots to get them thoroughly established by the end of autumn. A mulch of short manure applied at that period will then protect the surface from harm however severe the winter may be. When well attended to, these plants yield very heavy crops the following season. The earlier young plants or recently-rooted layers are planted in August the greater the prospect of a crop of very fine fruit the next season. All preliminaries in the way of preparing the sites for new beds should, therefore, be expedited so that the planting may be done at an early date. If they are to follow some crop for which the soil was well manured, nothing beyond a levelling of the surface and treading it afterwards to render it firm—the latter being very essential—is needed. If, on the contrary, manuring and digging have yet to be done, the matter should have immediate attention. Strawberries succeed best on loamy soils of a medium texture. On light and sandy loams the plants suffer severely from drought in a dry season unless they are kept well mulched and watered. When possible, such soils should receive a dressing of loam and cowshed manure prior to digging. Heavy and retentive soils are the better for a good coating of well-rotted manure and charred refuse. When a long succession is desired, not only must early maincrop and late varieties be planted, but they must be planted in various positions to ensure the fruit ripening in its proper season. For instance, the earliest should be accorded a border having a southern or south-western aspect. The maincrop sorts should be out in the open, and the later and latest in a position under a wall facing north-west and due north respectively. Before planting, give the plants a thorough soaking of water, and after having firmed the soil open out holes for each with a trowel large enough for some fine soil to be worked in round the balls and make all quite firm. Finish off by treading round each plant and mulch the surface with short manure. Shallow planting is as much to be avoided as the reverse; the correct way being to set them in the ground just deep enough for the top of the balls to be lightly covered with soil and no more. The usual distance for planting is 18 inches between the rows, the rows from 2 feet to 2½ feet apart, according to circumstances.

Early Apples and Plums.—Of the former, *Beauty of Bath* will soon be ready for use. As the fruits become woolly and lose flavour if gathered and stored, the best way is to gather and send them to table as they become fit for use. Heavily-laden trees of *Codlin* varieties may be relieved of a good portion of their crops, the thinnings being of service for cooking and baking. If the best of the fruits are left on the trees they will then grow to a much larger size than if the crop is left unthinned. As to *Plums*, *Early Prolific*, on a wall and in the open, is ripe enough for cooking, but requires another fortnight to render the fruits fit for dessert. Birds are so troublesome that it is absolutely necessary to net the trees if the fruit is to be preserved.

Wasps.—An unprecedented number of queen wasps was destroyed during the spring, but, in spite of this, there is already evidence that these insects will be very numerous in the latter end of the summer and early autumn. A good few very strong nests have already been found; for some time to come they will be sought for over a considerable area and

destroyed. If every landowner would only do the same thing the numbers of these pests would soon be very considerably reduced and in time almost extirpated.

Spring Cabbage.—The second sowing of seed to furnish plants for setting out to form a succession to the earliest raised in the latter end of July should take place now under precisely the same conditions as mentioned for the previous sowing. If space is restricted, the seeds may be sown between the newly-planted *Strawberries*. A single drill drawn between every two rows of the latter will do no harm if the young *Cabbage* plants are not left in the ground later than February.

Lettuces for spring use.—These may be raised in the same way if necessary, making a good sowing now of *Winter White* and *Bath Brown Cos* and again in a fortnight's time.

Cauliflowers.—These may also be raised on newly-formed *Strawberry* beds. The middle of the month is, for all general purposes, quite soon enough to sow. The three best varieties are *Early Giant*, *Early London*, and *Walcheren*.

Onions.—So long as the war continues, and no doubt for some time after, the present large demand for *Onions* will not abate. To cater for this should be the object of growers, and extra large breadths should be sown accordingly this autumn. The actual sowing need not take place for another fortnight or in three weeks' time will be early enough for the south, but the site where the sowing is to be done should be manured and dug in readiness. A border under a wall facing south or westwards makes a good seed bed, and from which plants can be drawn for transplanting early in February. Those set out in February of the present year are now swelling fast and require their tops to be kept bent over on one side. As soon as the tops begin to die off the bulbs should be pulled and laid out in full sun on shutters or mats to finish off, after which they should be stored in a cool, dry place.

Turnips. Good-sized breadths of these should be sown for winter use as fast as ground becomes available. As a rule, the raising can be effected with far less trouble at this date than earlier in the season. *Early Snowball* may still be one of the varieties sown, but the bulk of the drills should be sown with *Red Globe* and *Green-topped Stone*. For later sowings *Chirk Castle Black Stone* should be included. Sifted ashes from recently-burnt refuse, so long as it has not been allowed to get wet, may with advantage be strewn in the drills instead of artificial manure when the latter cannot be spared. If plentiful, the surface of the plots may be dressed with this material and incorporated with the soil in the process of raking it down to a fine condition. A.W.

MIDLAND COUNTIES.

Melons.—Melon-growing from now onwards will be more difficult than in early spring. Plants setting their fruits must be grown in a temperature not lower than 75 degs., and if there is danger of the figures dropping below this during dull or damp days, the hot-water pipes must be employed. Expose fruits that are ripening to the light and air, and stop all lateral growths closely. In these gardens the last batch of plants was planted on August 1st.

Pears.—As a result of early thinning, the fruits are swelling rapidly and the growth and foliage are clean and healthy. Varieties that ripen their fruits early have to be protected by nets, otherwise birds will damage them. Once *Pears* are pecked by birds, wasps and flies soon complete their destruction. *Pears* often suffer from lack of moisture at the roots at this season, and the result is seen in small, immature fruits. Trees carrying heavy crops will be greatly benefited by applications of liquid-manure or some quickly soluble fertiliser, washing the manurial properties well into the soil with water. Trees growing in thin, gravelly soil naturally require much more water than those planted in heavy soil. If not already done, no time must be lost in removing all superfluous shoots of hardy fruit-trees of all kinds. Whether

they are espalier, dwarf, pyramid, or standard trained trees, not a single shoot that is not wanted should be retained, as there is no danger of the buds at the base of the shoots breaking into growth after this date. American blight has been troublesome on some Apple-trees. A sharp look out is kept for this pest and the affected parts rubbed over with a stiff brush dipped in methylated spirit. In bad cases and where the trees are not bearing crops they have been syringed with a strong insecticide, repeating the application as often as necessary. The season has been a very difficult one for keeping the ground clear of weeds. An opportunity to destroy weeds, however, presents itself in the present hot weather. Keep the hoe constantly at work and go over the ground several times in quick succession. Hoeing serves also to check evaporation from the soil at a time when moisture at the roots is essential.

Begonia Gloire de Lorraine.—Plants that have filled their pots with roots are regularly fed with liquid-manure and the shoots neatly trained to form good shapely specimens. The plants will not need to be syringed overhead so frequently after this date, and as the days become shorter syringing will be discontinued. Allow plenty of space to each plant and gradually expose them a little to the sunshine. Schizanthus seedlings have been pricked off into boxes and stood in a cool frame, shading from bright sunshine. A batch of Roman Hyacinths and Polyanthus Narcissus has been potted up for early forcing. After potting they are plunged in ashes in a cool position, first soaking the soil in the pots with water. The propagation of summer-bedding plants will now be commenced in order to maintain stocks of the various plants. Pelargonium cuttings are best put into boxes. Use light, sandy soil which should be rammed as hard as possible. This will ensure hard, sturdy growth that will winter well. After inserting the cuttings they should be well watered and placed in an open, sunny position, where they may remain until it is necessary to remove them indoors for the winter. Cuttings of Ivy-leaved Pelargoniums, Fuchsias, Verbenas, Ageratum, Heliotrope, etc., will be put in as they become available.

Autumn-sown Onions have been lifted. In order to have the bulbs thoroughly ripened they are turned daily for at least a fortnight. When they are removed to the Onion loft they will require to be carefully examined that they may be kept as late into the autumn as possible. Onions sown in heat and planted out have done remarkably well, and are now nearing maturity. It is most important in regard to the keeping of Onions that they should be ripened and lifted early. The beds should be examined and all deformed bulbs removed. The rough skins should then be removed from the perfect bulbs to prevent them holding water, when the outer skin will ripen to a brown colour. By the end of the present month the whole of the crop should be carefully lifted and harvested. The main crop sown in the open has also made good progress, and will now have the tops turned down. This is best done with the hands, exposing the bulbs to the sun as much as possible. Preparations will now be made for sowing Onions to stand the winter. I find the best plan is to sow these on an open piece of ground and transplant in early spring. Some excellent varieties for successional planting are White Emperor, White Leviathan (two good early varieties), Blood Red, and Lemon Rocca.

Runner Beans do best when the growths are not allowed to become overcrowded. After the top of the supports is reached the shoots should be stopped to induce some of the bottom growths to break away strongly. The Runner Bean is a moisture-loving plant, and it can hardly be given too much water at the roots, even though the weather may be showery. Excepting those required for seed, the pods should be gathered immediately they become fit, as nothing tends to weaken the plants more than allowing the seeds to mature.

Peas.—At the time of writing Peas are very plentiful and exceptionally good. Successional and late varieties have been well mulched and thoroughly watered. Should the hot weather

continue it will greatly benefit the plants if they can be thoroughly syringed early every morning. If necessary to hasten the development of the Peas, pinch out the points of the shoots and remove all lateral growths.

Spinach.—Frequent sowings are still made in order to maintain a daily supply, choosing a cool position so that the plants may escape the afternoon sun. Winter Spinach is being sown in quantity.

Winter Lettuce seeds will shortly be sown for raising Winter Lettuces, the varieties used being All the Year Round and Hardy White Cos. The seeds will be sown on a south border, so that the plants may be ready early in November. A quantity of seedlings will also be transplanted into cold frames as soon as they can be shifted, allowing the lights to remain off until frost or heavy rains occur. Excessive dampness is frequently the cause of failure amongst Winter Lettuces. Allow the plants plenty of room, and keep the soil well stirred.

F. W. GALLOP.

SCOTLAND.

Nerines and Hæmanthus.—These valuable and showy bulbs are now thoroughly ripe, and may for a time be placed at the foot of a south wall fully exposed to the sun. When the embryo flower-stalk begins to push, the plants may be removed under cover. As the soil will be in a dust-dry state, it must then be thoroughly moistened, and the best way to do this is to plunge the pots to the rim in a tank until the ball is saturated. Afterwards the watering-pot can be employed without any apprehension that the ball is not thoroughly wet to the centre.

Lorraine Begonias.—These, as becomes necessary, must be potted on. It is as well to do this work by degrees, for it will be noticed some plants grow more quickly than others and are apt to suffer if allowed to remain unpotted till the bulk of the batch requires attention. Although at times troublesome in their younger stages, these Begonias make rapid progress after they go into 5-inch pots. Syringing occasionally is of advantage, and a light vaporising now and then lessens any risk from thrips, which occasionally attacks the plants. Careful watering after repotting is needed.

Pinks. Despite the rather untoward season, Pinks have been wonderfully good, and the display has been a prolonged one. The old white Pink, Her Majesty, Mrs. Sinkins, and various coloured varieties, chiefly seedlings, have been very effective. Now that the blooms are over, the withered heads are being removed, the greyish foliage being not without a beauty of its own when freed from dead flowers and stems. Now is the time to propagate if any increase of the number of Pinks is desired. If cuttings are put in thickly in a shaded cold frame or even in a cool place out-of-doors, they soon root, and make useful little plants which can be moved to their permanent quarters in late autumn.

Hardy annuals. In the course of the week a little time was spared to spring-sown hardy annuals just on the point of flowering. These have been used freely, if not in quite such a large variety as usual, and the sowings have turned out well. Masses of *Eschscholtzia californica* are always telling, so, too, are *Saponaria calabrica*, the various *Godetias*, and *Nemophilas*, while *Virginian Stocks* and *Poppies* are indispensable. In the course of cleaning among these and similar hardy annuals no compunction was felt in rooting out a few plants in places where they appeared to be too thick. The period of effectiveness in the case of these things is largely decided by the weather, but as soon as their beauty is on the wane they ought to be dispensed with, for nothing is so untidy as hardy annuals when their display is over.

Sweet Peas in lines and in clumps now take up a certain proportion of the time, as, if the blooms are not kept closely picked, seed-pods form and the bloom ceases. It is, therefore, just as well to have stated days on which the plants are relieved of their flowers. For some time, owing to the cold nights, bud-dropping was prevalent. At the time it was said that

this might be to the ultimate advantage of the plants, and so it proved. These have made superior growth, and the blooms which are now being freely produced have long and massive stems. In the event of the plants showing signs of distress, a dose of liquid-manure is recommended. Let this liquid be weak, for if it is given too strong the increased growth which follows will react on the blooms, and bud-dropping is occasionally found to follow over-feeding quite as much so as when cold nights occur. Keep the soil among lines and clumps well hoed up now that there is a certain amount of tramping over the surface to pick the blooms.

Hardy-flower borders grow increasingly attractive and put summer bedding plants entirely in the shade. Variety is now great, and the improvement in the weather during the past week has resulted in a greater brightness than has hitherto been the case. While watering some wall fruit-trees in the neighbourhood of some of the borders with liquid-manure an opportunity was taken of affording a good drenching to many large clumps of *Kniphofias*. These rapidly exhaust the soil, and unless given occasional waterings of liquid-manure or some other stimulant they are apt to deteriorate. The early kinds, especially the yellow *Lemon Queen*, are coming on rapidly. A useful and lasting family may be noted at this time in the *Achilleas*, of which a good selection is grown. *Lycnis chalcidonica*, both single and double, is bright. *Coreopsis grandiflora* and the various *Heleniums* and *Helianthus* provide, with the *Anthemises*, plenty of yellow. *Clematis recta*—or *erecta*, as it is sometimes called—is in full bloom, and *Phloxes* begin to make their presence felt. *Chrysanthemum maximum*—several good named kinds—is on the point of expanding, and *Asclepias rubra* is at present very handsome. *Galegas* are useful, if a trifle coarse. *Campanulas* are numerous, and the season of the *Anechuras* has been prolonged over a longer period than usual. The spikes of the earlier kinds of *Montbretias*, especially *Gerbe d'Or*, are fast becoming prominent, and blue *Veronicas* are numerous and showy. Something has apparently gone wrong with a fine piece of *Romneya Coulteri* in a south border, the plant looking far from healthy and, contrary to its habit, blooming sparsely.

Figs in pots.—The second crop is now advancing rapidly, and to assist this as far as possible a fresh top-dressing was given. As soon as the roots get to work in the new material, occasional supplies of artificial manure in solution will be given. In the meantime the syringe is kept at work morning and evening, for while Figs are not especially liable to insect attacks, yet in a close atmosphere during sunny weather thrips and red-spider occasionally made their appearance. It is of advantage if the pots can be plunged to half or three-quarters of their depth.

Peaches and Nectarines on walls.—During the week some considerable time was devoted to tying in the young growths of Peaches and Nectarines on the walls. The shoots are fairly vigorous, and slightly more numerous than is required, so a certain amount of thinning has to be done as the work goes on. In the meantime, the shoots have to be laid in so that they do not interfere with the rapidly swelling fruits. They will, of course, be put into their correct places during the winter training. Any obtrusive foliage is removed from the front of the fruits in order that they may be fully exposed to the sun.

Summer pruning in the case of Apples, Pears, and Plums is rapidly approaching completion. As soon as time permits, Plums and Pears will be watered either with liquid-manure or with a chemical substitute in solution.

Peas.—For some time misgivings were felt as to the success of this important crop; but with the renewal of fine weather the pods are filling in a satisfactory way. In the absence of material with which to mulch the lines, the Dutch hoe is kept at work among them at fairly frequent intervals. This not only keeps down weeds, but the fine tilth thus formed acts to some extent as a mulch and checks, if it does not prevent, evaporation.

Turnips. Thinning was done in the case of recently-sown lines, and a final sowing was made. There has been an entire absence of the Turnip-flea during this season.

Carrots just appearing above the soil have been freely dusted with soot. There is not now the same danger from the Carrot-fly, which has two periods of activity—one in spring (which is the more dangerous) and the second in mid-autumn.

Brassicæ.—Among the various Brassicæ the hoe is being vigorously employed when time can be found for the work. Growth is well maintained, and is especially noticeable among the early Brussels Sprouts. There is yet time to fill up vacant corners with such things as Early Ulm Savoy, Kale, and Spinach.

Celery.—The earliest-put-out plants will soon be ready for their first moulding. Although I am not convinced that early moulding is in the best interests of the plants, yet from long usage the orthodox custom is followed year by year. Previous to the soil being placed to the stems the trenches will be given a thorough watering. W. MCGUFFOG.

Balmæ Gardens, Kirkcudbright.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Ageratum seedlings (Miss Barton).—The only thing you can do is to pot the seedlings off singly into small pots, shifting them on as necessary until they are in 6-inch pots, in which they may be kept during the winter in a warm-house. Keep all the flowers pinched out, and next spring, if you have managed to keep them, you can increase them from cuttings.

Roses not opening (T.).—Your Rose is one of the varieties that do not open well in our country owing to the misguided efforts of raisers to get very double flowers. In a dry, sunny clime the variety might open better, but even in such a clime a few wet days will often prevent Roses from opening. The best way is to discard the plant and replace with one that opens well in your district. Among likely ones, we should name Rêve d'Or, Bouquet d'Or, and Gloire de Dijon.

Growing Cacti (D. L. Castle).—The soil best suited for the different kinds of Cacti is good loam lightened by an admixture of sand and brick rubble broken about the size of Beans. When potting is necessary it should be done in March or April, but one thing to bear in mind is that most of this class thrive best when pot-bound, hence care must be taken not to overpot. From this time to the end of August the soil must be kept fairly moist, after which less water should be given in order to ripen

the growth, while throughout the winter months they should be kept quite dry. The Phyllocacti, being of a less succulent nature, must not be dried to the same extent as the others, but even these need very little water during the winter. Most of the different kinds of Cacti can be raised from seed without difficulty; that is, when good seed can be obtained. Sow in well-drained pans in a mixture of loam and sand, sprinkling enough soil over to thoroughly cover the seed, but no more. The seed-pans are best stood in a warm, shaded structure, and the soil must be kept slightly moist at all times. Under such conditions the seed soon germinates, and, if sown in the spring, the young plants will attain sufficient strength to pass the winter without injury. When large enough to be conveniently handled, the seedlings must be put singly into small pots, taking care that good drainage is ensured.

TREES AND SHRUBS.

Cutting a Holly hedge (Miss Barton).—It is too late to do this. It should be cut into shape towards the end of April just before growth begins, using a sharp knife. Many people, to save time, use the shears in pruning a Holly hedge, but the knife makes by far the best work.

Buddleia variabilis Veitchiana, pruning (Canterbury).—Any pruning needed by this shrub and its several forms should be done in the spring before the plants start into growth. Even then it should be limited to the cutting away of any exhausted wood, unless it is desired to keep the plant within bounds. From the leaves you send us, we should say that the plant is dry at the roots and that the soil is exhausted. The soil may look moist on the surface, while further down it may be quite dry. Your best plan will be to loosen the surface-soil and give the plant a thorough soaking of water, then mulch it with some well-rotted manure and water freely, so as to carry the goodness of the manure down to the roots.

FRUIT.

Neglected Raspberry bed (N. Matthews).—Seeing your Raspberry bed is in such a bad condition and, as you say, overrun with Bindweed, the only thing you can do is to go through the plantation in the autumn and select what you require of the strongest suckers and make a fresh plantation on a piece of ground that has been well manured and deeply trenched. Plant in rows 4 feet apart and in clumps of three at 2½ feet apart. Plant in November, and cut all the canes back to 6 inches from the ground in the spring to cause strong suckers to break up. You can do nothing to the present plantation owing to its being so overrun with Bindweed, and the only thing you can do is to dig the canes up, burn them, and then have the ground thoroughly trenched, clearing out as the work goes on every particle of the Bindweed you can find.

VEGETABLES.

Management of Cucumbers (C. W.).—It is not so very often needful to thin out the fruit on Cucumbers, but it is absolutely requisite to thin the branches, which should never be allowed to become a thicket. As the plants grow, stop the main shoots at 2 feet or so in length, then as the side shoots show fruit pinch out the point of each one a joint beyond the fruit, and continue to do so. Still the plants will in time become too dense, and then some of the side shoots must be taken out altogether. When the plants are thus kept properly thinned and in good health there are rarely too many fruits. Of course, if wanted for show, the plants should not be permitted to carry more than three or four large fruits each at one time. For ordinary domestic use a strong plant may carry some eight or nine fruits at one time.

MISCELLANEOUS.

Fowls' manure (N. Matthews).—The manure from a fowls' run is very good for almost anything, but the run should be covered with sand or ashes, from off which the manure could be raked every day or so quite clean. Then, as collected, it should be smothered with soot, placed in a heap, and mixed with its hulk of soil, allowing it to so remain for a month, then turning it in and giving it yet a

further dressing of soot, still allowing the manure to remain to sweeten and become incorporated with the soil. If allowed to remain for three or four months, so much the better. Then spread it on the ground in spring, and just fork it in. A thin dressing suffices. It is a mistake to employ this manure solely, as a different dressing is desirable the following year.

SHORT REPLIES.

E. D. Daniel.—Seeing you give us no particulars as to the soil in which the plants are growing and their treatment, it is very difficult to give a reason for the failure. Have you been giving the plants any liquid or artificial manure, as either of these given too strong would cause the injury. Can you kindly let us have a complete plant of any of the plants that have been injured?—*H. S.*—Kindly send us a few samples of your Bean leaves, and we will do our best to help you.—*Omega.*—It is not at all to be wondered at that all your plants are so leggy seeing the ground is so shaded by hedges, wall, and house. This trouble is increased probably by heavy manuring. The only remedy you have is to do away with the hedge, which, in addition to shading the plants you have in the borders, robs the soil of all its goodness.—*Angelina.*—We fear the Pear-tree has been moved too often. You say nothing as to the soil in which it has been growing. Judging from the shoot you send, it is in a very bad condition and not worth keeping.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*X. Y. Z., Stechford.*—1, Campanula; 2, Campanula sp., flowers too far gone to name with any certainty; 3 and 7, Sedum pruinaum; 4, Veronica cupressoides; 5, Veronica lycopodioides; 6, Santolina incana.—*J. S. Purden.*—1, The Bladder Nut (Staphylea colchica); 2, Rosemary (Rosmarinus officinalis); 3, Polygonum cuspidatum; 4, Aralia filicifolia.—*W. D., Halifax.*—Campanula muralis.—*M. C. G.*—1, Dianthus deltoides albus; 2, Dianthus deltoides; 3, Aubrietia Dr. Mules; 4, Aubrietia Peter Barr; 5, Sedum spurium.—*A. C.*—1, Hieracium aurantiacum; 2, Tradescantia virginica; 3, Lunaria biennis; 4, Thalictrum minus.—*R. F.*—1, Sedum spectabile; 2, Coreopsis lanceolata; 3, Centranthus ruber; 4, Astrantia major.—*A. R.*—1, Malva moschata alba; 2, Achillea ptarmica fl.-pl.; 3, Anteanaria tomentosa; 4, Inula glandulosa.—*W. NOTES OF THE WEEK.

A Chilean shrub (*Eucryphia pinnatifolia*) on a Kentish hill.—This was in profuse bloom in mid-August at Emmets, Ide Hill, the distinct effect of the erect mass of creamy-white striking, the close view of flowers lovely beyond power of words to describe. With such myriads of flowers and buds one wonders how the tall bush could carry them and live on, all this strange beauty coming fresh when most of our spring and summer shrubs have passed out of bloom. In no Elysian valley in its own land could the shrub have carried more bloom than on this Kentish hill, where it has been growing for some years quite hardy and vigorous in soil freely strewn with Kentish ragstone, the garden about 700 feet above sea-level. Dwarfier shrubs are placed around the tree as a precaution against exposure of the stem.

Kniphofia Red Cap.—A brilliant and vigorous sort, a vivid scarlet cresting, and falling into a spike of fine clear yellow. Worth a place beside John Benary or any of the best. From Messrs. Wallace, Colchester.

Cynoglossum amabile.—A handsome blue and unlooked for annual flower, rich in colour and of rather taller habit than in its fellows in the same genus. In bloom early August.

Roscea caulioides.—This is blooming for the second time this year. Several flower-spikes have been produced for the second blooming, but the flowers are smaller than they were earlier in the year.—N. L.

Pentstemon Myddleton Gem.—A good kind fit to rival the other well-known "Gems" of the race, with a clear white throat set in the fine rose-pink colour. Another fine large kind is Mrs. Fulford, a rich red with white throat. From Messrs. Wallace, Colchester.
